Many inſects aſſociate together all their lives, others only for a certain period. Thoſe who live together proceed from the ſame moth who depoſited the eggs near each other, or laid them in a heap, and thus formed a kind of neſt. Theſe are generally hatched about the ſame time, and live together, forming a kind of republic. Theſe ſocieties include two, three, or four hundred individuals, and uſually live incloſed in a large web, like the lackey moth, (phal. neuſtria) and the ermine moth. Of theſe ſocial caterpillars there are ſome kinds which never quit the ſociety to which they belong, but paſs into the pupa form in the ſame neſt. One of the moſt remarkable of theſe caterpillar communities is that of the bombyx proceſſionea. Theſe live on the oak ſeparate till they arrive at a certain age, when they aſſociate together, and do not quit their ſociety till they acquire their perfect form. As the number of the caterpillars thus aſſembled is conſiderable, the neſt is alſo very large. They remain in their habitation till ſun ſet. When they go out one of the body precedes the reſt as a chief, whom they regularly follow. When the leader ſtops the reſt do the ſame, and wait till it goes on again before they recommence their march. The firſt file generally conſiſts of a ſingle caterpillar, which ſeries is ſucceeded by a double file, theſe by three in a row, which are then followed by files of five, and ſo on. They keep cloſe to each other, not leaving any interval either between the ranks or between thoſe in each rank, all following their captain in compact order, whether in a ſtraight or irregular courſe. After they have taken their repaſt they return to the neſt in the ſame order as they ſet out. This conduct is regularly purſued till they are full grown, when each ſpins a cone for itſelf in the neſt. It has been remarked, that though theſe caterpillars proceed often very far from the neſt, it is by no means difficult for them to get back again, becauſe they ſpin a thread in their route. The firſt leads the way, the ſecond follows ſpinning, the third ſpins after the ſecond, and ſoon forming thus a path of threads.

Upon the ſame tree, ſhrub, or plant, we often find numbers of caterpillars which have no affinity to each other, and of which the actions of one have no influence over the manners of the other; they may in this reſpect be conſidered ſolitary. There are others who ſeem ſtill more independent of each other even than theſe, becauſe they ſhun all intercourſe, conſtructing lodgments formed of leaves tied together with conſiderable ingenuity, in which they live as in an hermitage. The operation by which theſe caterpillars tie the leaves together is far ſurpaſſed by another kind, who fold and bend one part of the leaf till it meets the other. Theſe are again excelled by thoſe who roll the leaves which they inhabit. For this purpoſe the caterpillar makes choice of part of a leaf which it finds in ſome degree bent; here its work commences, the caterpillar moving the head with great velocity in a curved line, or rather vibrating it like a pendulum, the middle of the body being the centre on which it moves. At each motion of the head a thread is ſpun and fixed at that part to which the head ſeems to be applied. The threads are extended from the bent to the flat part of the leaf, and the curvature which is to be given to it. There is another ſpecies of which it is obſerved, that at each new thread it ſpun, the edges of the leaf inſenſibly approached to each other, and were bent more and more, in proportion as the caterpillar ſpun new threads; when the laſt thread was ſpun, that which preceded it was looſe and floating in the air. To effect this the caterpillar, after it has fixed a thread to the two edges of the leaf, and before it ſpins another, draws it towards itſelf by the hooks of its feet, and by this means bends the leaf; it then ſpins another leaf to maintain the leaf in this poſition, which it again pulls towards itſelf, and repeats the operation till it has bent the leaf in its whole direction. It now begins again placing the threads further back, upon the bent part of the leaf, and by proceeding in this manner it is rolled up; when it has finiſhed this buſineſs it ſtrengthens the work by faſtening the ends of the leaf together. The habitations thus formed are open at both ends, and within which the inſect feeds in ſafety. At the approach towards the pupa ſtate, the caterpillar lines the rolled leaf with ſilk, that the rougher parts may not injure it.

A great number of the ſmaller larvæ require an artificial covering to protect them. Some inhabit the interior part of leaves in which they form large oval or circular ſpaces; others form a kind of gallery within, which in ſome is ſtraight, in others crooked. Many of the tineæ are found lodged in cylindrical tubes or caſes, which they form of different ſubſtances cloſely woven with fine ſilken threads. The ſmall caterpillar found in neglected woollens and other ſimilar articles is of this kind, living in a cylindrical caſe, and producing a ſmall moth.

The phryganea larvæ conſtruct caſes ſomewhat ſimilar in form, and which are alſo open at both ends; in theſe the larvæ reſide, the outſide is formed of different ſubſtances, ſuch as bits of reed, ſtone, gravel, and ſmall ſhells, which they arrange and manage with ſingular dexterity. When they walk they only advance a few of the anterior rings of the body, training the caſe after them. When they are about to aſſume the pupa form they cloſe up the ends with ſilken threads.

But the habitations of theſe inſects, though conſtructed with ingenuity, are in no manner comparable with the architectural fabrications of many other inſects, as thoſe of the waſp, the bee, the common ant (formica), the white ant (termes), &c. The ſtructure of the neſts conſtructed by the common waſp, and the common honey bee, cannot be unknown to any reader. Among the habitations of the ſolitary, or thoſe called the wild bees, there are many which deſerve remark. Some of the bee tribe penetrate into the earth, where they form ſmall contiguous cavities, in each of which they depoſit an egg, with a ſufficient quantity of proviſions for the ſuſtenance of the larva. There is one kind whoſe neſt conſiſts of ſeveral cells artfully let into each other, but not covered with a common incloſure; each cell conſiſts of two or three membranes, inexpreſſibly fine, and placed over each other. The cavity in which the neſt is placed is ſmeared over with a layer of matter, like that of which the cells are formed, and apparently ſimilar to that viſcous humour which ſnails ſpread in their paſſage from one place to another. An egg is depoſited at the bottom of each cell, where, after it is hatched, the grub finds itſelf in the midſt of a plentiful ſtock of proviſion, for in each cell there is placed a quantity of paſte, or a kind of wax, which is to ſerve as food for the worm, and as ſupport to the wall of the cell.

Another ſpecies that forms its neſt under ground makes a perpendicular hole in the earth about three inches deep and cylindrical, till it comes within three-fourths of an inch of the bottom, when it begins to open wider. The ſuitable proportions being given, the bee proceeds to line with tapeſtry not only the whole of the inſide, but alſo the entrance; the ſubſtance with which it is lined is of a crimſon colour, and appears as very beautiful. This lining is formed of fragments of the flowers of the poppy, which the bee cuts out curiouſly, and then ſeizing them with her legs conveys them to her neſt. If theſe pieces are rumpled, ſhe preſſes them ſmooth, and then affixes to the walls of her cell; or if the piece ſhe has cut and tranſported is found too large, ſhe clips off the ſuperfluous parts, and conveys the ſhreds out of the apartment. After the bee has lined the cell, ſhe fills it nearly half an inch deep with a kind of paſte, proper to nouriſh the larva when hatched from the egg. When the bee has amaſſed a ſufficient quantity of paſte, ſhe folds the tapeſtry over the paſte and the egg, which is by this means incloſed as it were in a bag of paſte; and the bee then fills up with earth the empty ſpace that is above the bag. Another of the bee tribe is ſaid to conſtruct its neſt in the ſame way, with this difference only, that the lining is of the corolla of the roſe.

The carpenter bee (apis centuncularis) conſtructs her neſt in pieces of wood, whence the name; in this ſhe perforates long cylindrical hollows, which ſhe divides into ſtages, and depoſits her eggs, each incloſed in a curious cylindrical caſe formed of leaves, not quite an inch in length, and leſs than half an inch in diameter, and theſe are diſpoſed endwiſe one above another to the amount of ten, twenty, or more, the cylindrical perforation in the wood being two or three feet long, or ſometimes more. They bore the wood moſt commonly in the longitudinal direction of its ligneous fibres, but this is not always the caſe. There are ſeveral ſpecies of this order in appearance much like each other. The leaves which form the lining of the caſes in one ſpecies is that of the roſe.

The former are called the carpenter bees on account of the holes which they bore in the wood; there is another which bears the name of maſon bee, from the peculiar ſtructure of the neſt. Their manner of building is this: the bees collect with their jaws ſmall parcels of earth and ſand, which they glue together with a ſtrong cement, which is furniſhed from the proboſcis; and of this they form a ſimple but commodious habitation, which is generally placed along walls that are expoſed to the ſouth. Each neſt reſembles a lump of rude earth of about ſix or ſeven inches diameter, thrown againſt the wall; the labour of conſtructing an edifice of ſuch magnitude muſt be conſiderable, as the bee can only carry a few grains at a time. The exterior form is rude and irregular, but the art exhibited within more than compenſates for the ruggedneſs of the external appearance. The interior is divided into twelve or fifteen cells, ſeparated from each other by a thick wall; in each of theſe an egg is depoſited by the parent bee. The cells are conſtructed progreſſively, for when one is finiſhed ſhe places an egg in it, with a ſufficient quantity of honey to nouriſh the larva; ſhe then builds another, and ſo proceeds till all her eggs are depoſited. When the young are hatched the ſtrength of their jaws enable them to penetrate through their cells with perfect eaſe.

There is a ſpecies of ſphex called the ichneumon waſp, whoſe manner of conſtructing the neſt is ſtill different from either of thoſe before mentioned. This little creature generally begins its work in May, and continues its labours through the greater part of June. The object of her labour ſeems at firſt to be the digging of a hole a few inches deep in the ground, in the conſtruction of which ſhe forms however a hollow tube above ground, the baſe of which is the opening of the hole, and which it raiſes as high above ground as the hole is deep below; it is formed with great care, reſembling a coarſe kind of fillagree work, conſiſting of the ſand drawn from the hole. The ſand out of which ſhe excavates her cell is nearly as hard as a common ſtone. This it readily ſoftens with a penetrating liquor, with which ſhe is well provided; a drop or two of it is imbibed immediately by the ſand on which it falls, which is inſtantly rendered ſo ſoft, that ſhe can ſeparate and knead it with her jaws and fore feet, forming it into a ſmall ball, which ſhe places on the edge of the hole as the foundation ſtone of the pillar ſhe is about to erect; the whole of it is formed of ſuch balls, ranged circularly, and then placed one above the other. She leaves her work at intervals, probably in order to renew her ſtock of that liquor which is ſo neceſſary for her operations; theſe intervals are of ſhort duration; ſhe ſoon returns to her work, and labours with ſo much activity and ardour, that in a few hours ſhe will dig a hole two or three inches deep, and raiſe a hollow pillar two inches high. After the column has been raiſed to a certain height perpendicularly from the hole, it begins to curve a little, which curvature increaſes till it is finiſhed, though the cylindrical form is preſerved. She conſtructs ſeveral of theſe holes, all of the ſame form and for the ſame purpoſe. It is evident the hole was dug in the ground to receive the egg, but the purpoſe of the tube of ſand is not very apparent. By attending to the labours of the waſp, one end, however, may be diſcovered; it will be found to ſerve the purpoſe of a ſcaffold, and that the balls are as uſeful to the waſp as materials to the builder, and are therefore placed as much within her reach as poſſible. She uſes it to ſtop and fill up the hole after ſhe has depoſited an egg in the cell, ſo that the pillar is then deſtroyed, and not the leaſt remains left in the neſt. The parent inſect generally leaves ten or twelve worms as proviſions for the young larva.

In all theſe fabrications there is a degree of ingenuity in deſign, and exactneſs of execution, which, independently of the labour required in their conſtruction, excites our admiration. The talent, if it may be ſo expreſſed, of the inſect race, is more obviouſly diſplayed in the formation of the dwellings than in moſt other particulars of their hiſtory. It is a pleaſing ſubject of inquiry, and extremely worthy of attention, but for an elementary diſcourſe we have, perhaps, already purſued theſe obſervations to a due extent, and ſhall therefore conclude with a conciſe account of one other, which, from its ſtupendous dimenſions, the order, regularity, and beauty of its architectural deſign, and inimitable convenience to the purpoſes for which it is intended, cannot fail to excite the aſtoniſhment of every obſerver; it may be anticipated that the alluſion is to the buildings of the termites. Theſe diminutive inſects, known more generally by the name of the white ants, though, technically ſpeaking, they are entirely of a diſtinct genus, are natives of the Eaſt Indies, Africa, and the ſouthern parts of America. They live in ſocieties, each of which is compoſed of ſome thouſand individuals, all of whom are accommodated in the ſame habitation. Their ſtructures are of a pyramidal form, riſing to the height of ten or twelve feet, and covering no inconſiderable extent of ground at the baſe. They uſually build in the plains ſeveral contiguous to each other, and from their ſize and form may ſometimes be miſtaken at a diſtance for the huts of the natives.

Theſe neſts are ſo common all over the iſland of Bananas, and the adjacent continent of Africa, that it is ſcarcely poſſible to ſtand on an open place where one of theſe buildings is not to be ſeen. The domes are ſo ſtrong that they will eaſily bear the weight of three or four men ſtanding on them at once, and ſhelter the interior from every attack of the weather. The interior is divided with the utmoſt regularity into an immenſe number of apartments, arched chambers, magazines, and avenues leading to them; and the centre, on a level with the ground, contains the royal apartment, in which the queen reſides, ſurrounded by the nurſery, &c. The white ant is the termes fatale: there are two, if not more, ſpecies beſides, namely, deſtructor and arda, both inhabitants of Africa, which build neſts of a ſimilar form, but of much ſmaller ſize. See the article TERMES.

Food of Inſects.

Inſects feed on all kinds of vegetable and animal ſubſtances. There is ſcarcely any production of theſe two kingdoms which does not ſerve for food to ſome kinds of inſects. They may therefore be conſidered under two heads; thoſe which live on vegetables alone, and thoſe ſupported chiefly on animal food. The organs of the mouth point out the very wide diſtinction nature intended in this reſpect, ſome being adapted to the purpoſes of maſtication, others to that of ſuction only; ſome, like ruminating animals, have two ſtomachs, others only one; the alimentary canal in ſome is ſhort, in others long, and upon the whole, their internal conformation, as well as external form, preſents the moſt ſtriking differences, each being in a peculiar manner adapted to the nature of the food upon which the animal ſubſiſts.

There is yet another circumſtance well worthy of remark; in all thoſe inſects which undergo material change, the transformation of their external figure is accompanied with an entire revolution in their internal ſtructure and economy; the larvæ deſtined to feed on vegetables, or the grub on carrion, after effecting their transformation, preſent no longer the ſame appearance within; parts adapted to their former mode of life, and inapplicable to their preſent one, totally diſappear, and other organs, either before not exiſtent, or which remained concealed, are now developed. The ſtomach of the butterfly, when in the larva ſtate, is adapted to the reception and digeſtion of its vegetable food, as its organs of maſtication are to its previous preparation; but this ſtomach and this mouth both diſappear in the butterfly, and other organs make their appearance; its mode of life is totally changed; it derives its ſuſtenance from the nectar of flowers, and its whole conformation is adapted to its new mode of life. Theſe arguments are not inferred from a few ſolitary inſtances; they are exemplified in numberleſs examples: nothing is more common than to find the larvæ ſubſiſting on food altogether different from that which ſupports the ſame inſect in the winged ſtate.

Among thoſe numerous tribes which feed on vegetables, ſome ſink into the earth, where they feed on the roots of graſs, and do conſiderable injury to gardens. The food of others is dry and hard; they pierce the wood, reduce it to powder, and then feed on it: in this manner many of the cerambyx tribe and other coleoptera feed in the larva ſtate. Some attack the leaves, eating the whole ſubſtance, except the principal nerves; while others feed only on the parenchymous parts which are contained between its ſuperficial membranes, forming paths and galleries within. Theſe inſects are not always content with the leaf; ſome eat the flowers, and even this food is too groſs for many; the bee, the butterfly, the muſca, and a hoſt of others, feed only on the nectareous juices, or the farina which they collect from flowers, or the delicious fluids of fruits. Corn and other grain are not free from them; they divide the produce with us, or often deprive us of large quantities. They inſinuate their larvæ into the moſt tender parts, and each oftentimes deſtroys more than would be ſufficient to feed fifty of them. We frequently find the larvæ of ſome inſects in pears, plumbs, peaches, and other fruit. There, indeed, appears ſcarcely any part of a plant which does not ſerve as food to different inſects; each has its appropriate food, and though the parent animal does not, perhaps, ſubſiſt on the ſame vegetable, yet ſhe inſtinctively depoſits her eggs on that particular ſhrub or plant which will be food for her young: Some more voracious than the reſt feed upon all with equal avidity; the migratory locuſt, gryllus migratorius, is a ſtriking example of this. The ravages of this inſect have been at particular times ſo extenſive as to lay waſte the vegetation of whole diſtricts, of even kingdoms; an inſtance is mentioned in the Amœnitates Academicæ, in which they over-ran all Sweden, and devoured all the plants, inſomuch that cattle periſhed with hunger, and men were forced to abandon their country, and fly to the neighbouring regions. Similar reſults have ariſen from the ravages of locuſts in various parts of the world at various periods, as appears from the moſt credible hiſtorians. The ſacred writings are not ſilent on this ſubject. In the year 593 of the Chriſtian era theſe animals appeared in ſuch vaſt numbers, as to cauſe a famine in many countries. Syria and Meſopotamia were over-run by them in 677. In 852 immenſe ſwarms took their flight from the eaſtern regions into the weſt, and deſtroyed all vegetables, not even ſparing the bark of trees, and the thatch of the houſes, after devouring the crops of corn, graſs, &c. Their daily marches were obſerved to be about twenty miles each, and it is ſaid their progreſs was directed with ſo much order, that there were regular leaders among them, who flew firſt and ſettled on the ſpot which was to be viſited at the ſame hour the next day by the whole legion; their marches were always undertaken at ſun-riſe. In 1541 incredible hoſts afflicted Poland, Wallachia, and all the adjoining territories, darkening the ſun with their numbers, and ravaging all the fruits of the earth. The years 1747 and 1748 afforded a memorable inſtance of the ravages of theſe animals in Germany and other parts of Europe, as far north as England. In the eaſtern parts of the world ſuch flights of locuſts appear more frequently than in Europe, and it is often found neceſſary for the governors of particular provinces to command a certain number of the military to take the field againſt armies of locuſts with a train of artillery.

The far greater number of inſects feed, however, more diſcriminately; ſome are confined to one particular plant, and others only to two or three kinds; and neither in many caſes will eat any other food; they often periſh in the midſt of abundant vegetation, becauſe they cannot procure that kind which is their natural food. The quantity of food which a caterpillar will devour is aſtoniſhing; that which feeds upon the cabbage (papilio braſſicæ) deſtroys in twenty-four hours more than twice its weight. If larger animals required a proportionable quantity of food, the earth would not be able to nouriſh its inhabitants. It ſhould, however, be remembered, that it is only during one period of their lives that they are ſo voracious, or ſubſiſt on ſuch food; after they quit the larva form they are nouriſhed in a different manner.

A vaſt number of inſects reject vegetabes in the larva ſtate, and live only on animal food; ſome ſeeking that which is beginning to putrefy, while others delight in that which is entirely putrid, or on the dung of animals. Some attack and feed on man himſelf, while others are nouriſhed by his victuals, clothes, furniture, and habitation; and again others prey on his cattle. No animal whatever is exempt from theſe depredators. Some ſubſiſt on the blood and humours of quadrupeds, others of birds, and a great proportion of them prey on inſects of other kinds, or often attack their own, and thus perpetuate an endleſs war among each other.

Every larger animal has its appropiate lice, which feed on and infeſt it: theſe in ſize or voracity bear no regular proportion to the animal they ſubſiſt upon. Thoſe of man are diminutive in the extreme, compared with thoſe which torment ſome animals. The hippoboſcæ and the tick, though not in technical terms the lice of the animals they infeſt, have the ſame habits, and draw nouriſhment from the body in the ſame manner; and theſe, in comparative bulk with the victims of their depredation, are an hundred, nay even, in ſome inſtances, a thouſand times larger than theſe uncleanly vermin in man. Some are not content with the blood and juices which they ſuck from animals; they ſeek their food in the fleſh, and that while full of life and health. The oeſtri, or gad-flies, are familiar examples of this, the larva feeds upon the fleſh beneath the ſkin in cattle. The parent lodges its eggs in the fleſh by making a number of little wounds, in each of which it depoſits eggs, ſo that every wound becomes a neſt, and the eggs are hatched by the heat of the animal. Here the larva finds abundance of food, and is at the ſame time protected from the changes of the weather, and they undergo their transformations in ſecurity. The parts they inhabit are often diſcovered by a lump or tumour which they occaſion; this ſuppurates, and is filled with matter, in which the head of the larva is always found plunged. When the time of change arrives the larva drops out, and ſeeks a convenient place in the ground, where it paſſes to the pupa ſtate. The ravages of the larva hatched from the ichneumon eggs, in the body of the caterpillar, are ſtill more deſtructive, as they entirely deſtroy the vitals of their victims. The number of inſects which are of a carnivorous diſpoſition is very great; and it is among theſe we find the traces of the greateſt art and cunning, as well for attack as defence. Every one is acquainted with the dextrous arts of the ſpider, to ſeize his prey, the curious neſt he ſpins, and the central poſition he aſſumes in order to watch more effectually the leaſt motion communicated to its tender threads when the incautious inſects ſettle upon it. D.

ENTONNER, *Fr.* in *Roman Catholic Churches*, is announcing to the choir the tone or ſound with the organ, or the voice of the officiating prieſt, with which a chant, hymn, pſalm, or anthem is to begin. In our cathedrals this is done for the reſponſes by a canon, vicar choral, or by a ſingle note on the organ.

ENTORSIS, in the *Manege*. See PASTERN.

ENTOYER, or ENTOIRE, in *Heraldry*, is uſed to expreſs a bordure, charged entirely with things without life. See BORDURE.

ENTRACQUE, in *Geography*, a town of Italy, in the principality of Piedmont, on the Geſſo; 5 miles S.S.E. of Demont.

ENTRA'CTE, *Fr.* the ſpace of time which elapſes between the end of one act of a drama and the beginning of another; and during which the repreſentation is ſuſpended, while the action is ſuppoſed to be advancing elſewhere. The orcheſtra fills up this ſpace by performing a ſymphony, which ſupplies the place of what uſed, in England, to be called an *act-tune*.

It does not appear that the Greeks ever divided their dramas into acts; conſequently, they had no act-tunes. The repreſentation was never ſuſpended on their ſtage empty from the beginning of the piece to the end.

The Romans, leſs intereſted in theſe exhibitions than the Greeks, were the firſt who divided their pieces into ſeveral diſtinct parts, the intervals of which afforded a relaxation to the attention of the ſpectators; and this cuſtom has been continued elſewhere ever ſince.

But as the entract was intended to ſuſpend the attention, and give ſome repoſe to the mind of the audience, the ſtage ſhould have remained vacant. But the interludes with which the vacuity was formerly filled furniſhed an interruption in a very bad taſte, which infallibly injures the piece in breaking the thread of the action.

However, Moliere himſelf did not ſee ſo ſimple and obvious a truth; the ſpaces between the acts of his laſt pieces were filled with interludes.

The French, whoſe public ſpectacles have more reaſon than enthuſiaſm in them, and who dread being long kept in ſilence, have ſince reduced their interacts to their due ſimplicity, and it is to be wiſhed for the perfection of the drama that they were imitated, in that particular, every where elſe.

The Italians, whom an exquiſite ſenſibility often guides better than reaſon, have proſcribed the dance of the dramatic action (ſee OPERA); but by an inconſiſtence ariſing from the too long duration which they allow to their repreſentations, they fill their interacts with ballets, which baniſh them from the piece in repreſentation, and if they avoid the abſurdity of a double imitation, they give into an equal abſurdity by a tranſpoſition of ſcene, and by haraſſing the ſpectator from object to object, they make him forget the principal action, loſe the intereſt, and, in order to give pleaſure to his eyes, rob him of thoſe of the heart.

They began, however, to feel (in 1768) the defect of this monſtrous aſſemblage; and after having already almoſt driven intermezzi from their ſtage, they will doubtleſs, ere long, get rid of the dance, reſerving it only as a brilliant and detached ſpectacle at the end of the grand piece.

But though the ſtage remains vacant during the interact, it is not to be underſtood that the muſic ought to be ſilenced; for at the opera, where it conſtitutes the principal exiſtence of every thing, the ſenſe of hearing ought to be ſo connected with that of ſight, that as long as the ſtage is ſeen the harmony ſhould be heard, which is ſuppoſed inſeparable from it; ſo that its concurrence may not appear afterwards foreign or new, but united with the melody of the vocal performers. Chiefly from Rouſſeau.

The difficulty which preſents itſelf on this ſubject, is to ſuggeſt what the compoſer ought to dictate to the orcheſtra when nothing is doing or tranſacting on the ſtage: for if the ſymphony, as well as all dramatic muſic, is only a continued imitation, what is it to ſay when nobody ſpeaks? What ought it to do when there is no action? "I anſwer to that (ſays Rouſſeau) that though the ſtage is vacant the heart of the ſpectator is not; there ought to remain a ſtrong impreſſion of what has been ſeen and heard. It is for the orcheſtra to cheriſh and ſuſtain this impreſſion during the interact, that the ſpectator at the beginning of the enſuing act may not find himſelf as cold as at the beginning of the piece, but that the intereſt may be as much linked in his mind as the events are in the action repreſented.

By this means the muſician will always have an object of imitation, either in the ſituation of the perſonages, or in that of the ſpectators. Theſe ſhould hear nothing from the orcheſtra but expreſſions of what they have felt, identified with what they hear; and their ſituation will be ſo much the more delicious, as there ſhall be a more perfect accord between that which ſtrikes their ſenſes and which touches the heart.

An able muſician will draw from the orcheſtra another advantage, which will contribute to give the repreſentation all the effect poſſible, in conducting the ſpectator, by degrees, to the ſtate of mind the moſt favourable to the effect of the ſcenes which are going to be repreſented in the following act.

The interact has no fixed duration; but it is ſuppoſed to be more or leſs conſiderable, in proportion to the time neceſſary for that part of the action, which is paſſed behind the ſcenes. However, that duration ſhould have its bounds of ſuppoſition, relative to the hypothetic duration of the whole action; and the real bounds relative to the duration of the whole repreſentation.

This is not the place to examine whether the rule of 24 hours is well founded, and if it ought never to be violated. But if we would give to the ſuppoſed duration of an interact bounds regulated by the nature of things, I ſee no other rule than that of the time during which no ſenſible and regular change happens in nature, which cannot be made apparently tranſacting on the ſtage during the interact. Now this time being 12 hours, which compoſe a day or a night, if that is exceeded, there is no longer any poſſibility of illuſion during the ſuppoſed length of the act."

This is reviving the old contention concerning the unities, which have never been received as a law in this country. And as to act-tunes analogous to the buſineſs of the drama, it is an idea which was executed by Purcell in many of the plays of Dryden and Congreve; and Arne, when compoſer in ſalary at Drury-lane theatre, compoſed very pleaſing and appropriate act-tunes to many of the ſtock plays, which never were printed, but preſerved in MS. in the archives of the old theatre; but we ſuppoſe that the ſtrains of Orpheus or Amphion might be as eaſily recovered now as theſe compoſitions.

ENTRAIGUES, in *Geography*, a ſmall town of France, in the department of the Aveyron, chief place of a canton, in the diſtrict of Eſpalion, with a population of 1748 individuals. It is ſituated near the place where the river Truyere falls into the Lot, 18 miles S. of Aurillac. Its canton contains 6 communes, and 6691 inhabitants, on a territorial extent of 147½ kiliometres.—Alſo, a ſmall town of France, in the department of the Iſére, chief place of a canton, in the diſtrict of Grenoble, with a population of 521 individuals. The canton contains 10 communes and 4988 inhabitants, on a territorial extent of 355 kiliometres.—Alſo, a ſmall town of France, in the department of Vaucluſe, 6 miles N.E. of Avignon.

ENTRAILS, the inteſtines or guts of an animal. See INTESTINES.

Menage derives the word from the barbarous Latin, *interalia*, formed of the Greek, εντερον, *inteſtine*.

ENTRAILS is alſo uſed, in a more extenſive ſenſe, for the viſcera, or all the parts contained in the cavities of the bodies of animals. See VISCERA.

The aruſpicina of the ancients was employed in conſidering the entrails of victims; as the heart, lungs, liver, &c. See ARUSPICES, &c.

ENTRANCE, in *Sea Language*, is a name often given to the foremoſt part of a ſhip under the ſurface of the ſea.

ENTRANCE *of hounds*, a phraſe uſed by our *Sportſmen*, to expreſs the inſtruction of theſe creatures in the art of hunting. They are ſaid to be entered when they are thoroughly taught this.

The time of entering of hounds is when they are about twelve months old; when they are firſt brought up from their walks, they ſhould be kept ſeparate from the pack: they are then to be taught to take the water and ſwim; they are to be laid abroad in the heat of the day, to enure them to fatigue and exerciſe; and they muſt be frequently led through flocks of ſheep, and warrens, to uſe them to be under command, and to know that they are to run at nothing but what the huntſman orders. They muſt be carefully inſtructed each to know his own name, and to underſtand the voice of the huntſman, and the notes of the horn uſed in hunting; and finally, to uſe their own language in a proper manner. When young hounds well know and anſwer to their names, they ſhould be put into couples, and walked out amongſt ſheep; and if any be particularly ſnappiſh leave the couples looſe about their necks in the kennel, till they are more reconciled to them. If any of them ſhould be very troubleſome, couple them to old hounds, always avoiding coupling two dogs together, if poſſible, and taking care that the couples be tight enough to prevent their heads being ſlipped out of the collar. After being walked out frequently amongſt the ſheep, they may be uncoupled, a few at a time, and ſuch as offer to run after them ſhould be well chaſtiſed; the cry of *ware, ſheep*, will afterwards ſtop them, without further application of the whip; proper attention will ſoon make them aſhamed of it; but if once ſuffered to taſte the blood, it will be difficult to reclaim them. If young and old hounds are aired together, let the former be in couples; they are always ready for miſchief, and idleneſs may induce even the latter to join in it. It may be as well to air the young hounds in that country where they are deſigned to hunt, as they thus acquire ſome knowledge of it, and if at any time they ſhould be left behind, they will more readily find their way home. Young hounds ſhould be entered as ſoon as you can; in woodlands and graſslands, it will of courſe be earlier than in corn countries. Sport in fox-hunting cannot be ſaid to begin before October; but in the two preceding months, a pack is either made or marred.

The beſt time of entering them is about noon; and it ſhould be in a fair warm day; for if they be entered in the morning, they will give out when the heat of the middle of the day comes on, and betake themſelves to ſhady places to reſt and ſleep. Accordingly it is ſaid that hounds ſhould be entered in the heat of the day, and about October or November, for hare-hunting, the weather being then temperate, and young hares that have not been hunted are then more eaſily taken for their encouragement. A neceſſary caution is alſo added, never at the entering of young hounds to help them to kill the hare with grey-hounds, for this will deter the hounds from putting their noſes to the ground, or trying to hunt her themſelves. Take the moſt advanced, that the game may not ſtand long before them, and let them be well rewarded when all is over. This ought to be repeated at leaſt once a week, for two months ſucceſſively; by this means they will be ſo fleſhed and ſeaſoned with what game you may enter them at, that they will never afterwards leave off the purſuit. Hounds, after two years old, ſhould be hunted three times a week, if they feed well, and may be kept out the greateſt part of the day to try their ſtoutneſs. The new hounds ſhould always be entered with the beſt and ſtauncheſt hounds that can be had; and there is not to be one barking dog ſuffered in the field on this occaſion.

Whatever chace the hounds are intended for, it has been ſaid that the hare is the beſt game to enter them at, becauſe in this chace, they will learn all the turns and doubles that they can poſſibly meet with in any other kind, and how to come to the hollo. They will learn alſo from this chace, to have a perfect and nice ſcent, and hard feet, by being uſed to highways, beaten paths, and dry hills.

On the other hand, it has been more reaſonably maintained, that young hounds ſhould always be entered at their own game; becauſe it is a ſtrange contradiction to enter them at a hare, and then to cut them to pieces for afterwards hunting the hare. This, it is ſaid, is laying a foundation for future cruelty and vexation. Moſt dogs like that ſcent beſt, which they were firſt blooded to; and if the blood of the fox be of ſo much ſervice, that of the hare cannot be deemed a matter of indifference. It is, therefore, without doubt moſt rational to uſe them to that ſcent *only*, which it is intended they ſhould hunt. It has been aſſerted, that the way to render hounds ſteady from hare, is to encourage them to hunt her. The advantage reſulting from this kind of paradoxical practice is ſaid to be, that hounds are thus taught to hunt, and made to learn obedience; but the ſurer method to make hounds obedient is calling them over often in the kennel, to accuſtom them to their names, walking them out frequently amongſt ſheep, hares, and deer, from which they are to be ſtopped, to make them know a "rate;" and by this practice they will learn obedience. Nature will inſtruct them how to hunt: art is only neceſſary to prevent their hunting what they ought not to hunt. Should any young hounds be very fond of hare, let ſome be found ſitting, and ſtarted before them, they will ſoon be checked and ceaſe to run after them. If they are to be ſteadied from deer, they ſhould often ſee deer, and they will not regard them. After this probation, a cub ſhould be turned out before them, with ſome old hounds to lead them on, and they will not long give trouble. After young hounds ſtoop to a ſcent, are become handy, know a "rate," and ſtop eaſily, put them, a few only at a time, into the pack after the old ones have been hunted and had blood; let them be taken the firſt day where they are certain of finding. Hounds ſhould be low in fleſh when hunting commences; becauſe the ground being generally hard at that ſeaſon, they are liable, if luſty, to be ſhaken. If foxes are plentiful, take the young, with ſome of the ſteadieſt of the old hounds, where there is leaſt riot, and ſhould you there find a litter of foxes, the young hounds will be ſo much improved as to need little ſubſequent inſtruction. If any cubs be ran to ground, and blood be not then wanted, let them be brought home, and they will be ſerviceable, ſhould blood be neceſſary at any time for the young hounds. Frequent hallooing is of uſe with young hounds, as it keeps them forward, prevents their being loſt, and from hunting after the others: the more, therefore, a fox is ſeen and hallooed, the better. Young hounds are thus made eager, and taught to exert themſelves. At their firſt entering, hounds cannot be encouraged too much: when they are handy, love a ſcent, and begin to know what is right, it will be ſoon enough to chaſtiſe them for doing wrong; in which latter caſe, one ſevere beating will ſave much trouble. The whipper-in ſhould uſe his voice as well as his whip, when he flogs a hound, and take care that the ſtroke precedes the "rating;" and he ſhould remember, that the ſmack of the whip is often as ſerviceable as the laſh to one who has already felt it. The day after young hounds have had blood is a proper time to take them where there is riot, and if they merit it, to chaſtiſe them: it is always beſt to correct them, when they cannot help knowing what they are corrected for. When hounds go out for this purpoſe, it ſhould be at a late hour; as the worſe the ſcent is, the leſs inclinable will they be to run it, and the ſtopping of them will be more eaſy and immediate. Upon the day when a fox is propoſed to be turned out, young hounds ſhould draw ſmall covers and furze brakes, where are hares or deer; a little rating and flogging, before they are encouraged to vermin, teaches them both what they ſhould not and what they ſhould do. A hound that hears a voice which has often rated him, and the whip he has often felt, ought to ſtop: when hounds are rated, and do not anſwer the rate, they ſhould be coupled up immediately, and made to know the whipper-in. A moſt eſſential point in rendering hounds obedient is to make them underſtand you; and therefore the language ſhould be appropriate and uniform. Young hounds ſhould be hunted in large covers to tire them out, provided the whipper-in can eaſily get at them; but when there is much riot there are no openings, the purpoſe will not be anſwered, unleſs you have a body of old hounds to carry on the right ſcent: for the young hounds, as ſoon as the ground becomes foiled, will be ſcattered about the cover, hunting old ſcents, and will not proceed faſt enough to tire themſelves. Beſides, every fox-hound will leave a bad ſcent of a fox for a good one of either hare or deer, unleſs he has been made ſteady from both. Young hounds are all given to riot; but the better they are bred, the leſs trouble will they be likely to give: high bred fox-hounds love their own game beſt: they ſhould have little reſt; one day they ſhould be hunted in large covers, where foxes are plentiful; the next, they ought to be walked out amongſt hares and deer, and ſtopped from riot; and the day following, be hunted again as before. By this management young hounds will ſoon become ſteady. At firſt young hounds ſhould be entered to vermin only; and they ſhould be uſed as early as poſſible to the ſtrongeſt and thickeſt woods and furzes, and they will ſeldom be ſhy of them afterwards. By being awed from hare and deer, and being taught to hunt only vermin, hounds will ſtop at a word, becauſe that word will be underſtood by them; and a ſmack of the whip will ſpare the inhuman trouble of cutting hounds in pieces for faults, which, if entered at hare, they have been invited to commit.

In hare-hunting the hounds, when firſt entered, muſt have all the advantages given them that can be. When the hare is put up, from her form, it muſt be obſerved which way ſhe went, and the ſcent muſt be left to cool a while, and then they muſt be laid in, and helped as much as can be, by wind, view, hollo, or pricking the paſſage; nor will it be amiſs, for the firſt time, to give them a hare tired the ſame morning in her courſe.

Some are of opinion, that the beſt way to enter young hounds is, to take a live hare, and trail her upon the ground, ſometimes one way, and ſometimes another, and then to draw her off to a convenient diſtance, and hide her, that the dogs, taking the ſcent, may follow all the traces through which ſhe was drawn, and at length find her.

It has been ſaid, however, that beating the hare up from her ſeat is a ſhorter way than trailing her from her feed to her form. Great exactneſs was formerly obſerved in the firſt entering of hounds, not to uncouple them repeatedly in the ſame ſort of ground, leſt by being uncoupled conſtantly in an open field, they would be at a loſs what to do when turned into a cover. It was a received opinion, that according to the places where hounds were firſt entered, they would ſhew a preference: *e. g.* if entered in a champaign country, they would always hunt better there than in covers, marſhy, or mountainous grounds. Hence it was deemed right to uſe them to every ſort of ground, and diverſity in the country was ſtrongly recommended, that they might be perfect in all. Some lands, which were of a glutinous and greaſy ſhining mould, never bore any ſcent, and there the huntſman was to help out the dogs by pricking the hare. In plains and downs where the graſs was ſhort, and the ſcent dried immediately, there alſo he was allowed to follow his game by the eye, in order to aſſiſt the noſe of the hounds. Some of the early ſportſmen never permitted the hare to be hallooed, or the hounds to be aſſiſted when they were at fault, but ſuffered them to work it out by themſelves; and this, though tedious, was conſidered a ſure way to aſcertain the goodneſs of the hounds: others took all advantages, and killed them as ſpeedily as poſſible. The method of rewarding the young hounds was curious. The hare, after being laid upon the graſs, and bayed by the hounds, was ſkinned before them; and after the gall and lights were taken away, which were ſuppoſed to make the hounds ſick, the huntſman, who carried a wallet with bread cut in ſmall pieces, dipped them in the blood, and with the entrails gave them to the hounds; the hare was afterwards diſtributed, and if any young hound was fearful to come in among the reſt, he had the head given him by himſelf. After this feaſt, the hounds had bread given them to prevent ſickneſs.

The huntſman ought very well to underſtand the nature and diſpoſition of his hounds, in finding out the game; for ſome hounds are of that temper, that when they have found the ſcent, they will run forward with it, not making any noiſe, nor ſhew of the tail; others, when they have found a head, will ſhew the game; and ſome, having found the footings of the beaſt, will prick up their ears a little, and either bark, or only wag their ears, or the hinder part of their bodies. This difference of natural diſpoſition, the huntſman is particularly to obſerve in the young and newly entered pack, otherwiſe he will never underſtand them, nor ever be able to hunt them to any credit or advantage.

For entering the hound at hart or buck, he ſhould be in the prime of greaſe, for then he cannot ſtand up, or hold the chace ſo long. The foreſt pitched upon ſhould have all the relays at equal diſtances, as nearly as may be; but then the young hounds ſhould always have ſome old ſtaunch ones to enter them, and they ſhould be led to the fartheſt and laſt relay, and the hart or buck ſhould be hunted to them. Being come up, the old hounds ſhould be uncoupled; and when they have found the hart, and well entered the cry, then the young ones are to be uncoupled alſo; and if any of them are found to lag behind, they muſt be whipped and beaten forward.

In whatever place the hart is killed, the neck ſhould be immediately flayed, and the hounds rewarded; for it is beſt always to do this while the fleſh is hot. Another very good method of entering hounds at the buck, is to take one in the toils or nets, and to wound one of his legs, ſo as to diſable him from running either very ſwiftly or very far: then let him looſe, and firſt let a blood-hound trace the creature, then let looſe all the young hounds; and when they have run down the animal, reward them with the neck.

Some enter their hounds with a toil; but this is a bad way; for the hart being in this caſe always in ſight, and not able to run an end, makes a great number of doubles and turnings: this is very different from the chaces they are to meet with afterwards; and when they find a hart run in the common way, ſtraight forward, and out of ſight, they will leave the chace, as unlike that by which they were taught. Daniel's Rural Sports. See Hunting.

ENTRASME, in *Geography*, a ſmall town of France, in the department of Mayenne; 6 miles S. of Laval.

ENTRAVES, Entravons, in the *Manege*. See Locks.

ENTRE Ambos os Rios, in *Geography*, a town of Portugal, in the province of Entre Minho Douro; 8 miles S.S.W. of Amarante.

Entre *Minho Douro*, a province of Portugal, ſo called from its ſituation between the rivers Minho and Douro, bounded on the north by Gallicia, a province of Spain; on the eaſt by Trazos Montes and Spain; on the ſouth by the province of Beira, from which it is ſeparated by the Douro; and on the weſt by the Atlantic ocean; and extending from 40° 50′ to 42° N. lat., and from 8° 55′ to 7° 55′ W. long., being 70 miles in length and 52 in breadth. It contains 963 pariſhes, 1460 churches, 1130 convents, 6 ſea-ports, and 804,000 inhabitants. This is the moſt northerly, the moſt fertile, and the moſt populous territory in the kingdom. Its numerous and fine vallies are ſhaded by beautiful trees, and watered by limpid ſtreams. Its air is pure and healthy; and it produces corn, wine, oil, and flax in abundance, with a great number of ſheep, and plenty of game and fiſh. The principal towns are Braga, Oporto, Viana, Amarante, Guimaræns, Ponte de Lima, and Pezo de Regna. Its chief rivers are the Minho, Lima, Neiva, Cavado, Ave, and the Douro or Duero, augmented by the Tamega; all of which run weſtward to the ſea.

ENTRECASTAUX, a ſmall town of France, in the department of the Var, near Barjols.

ENTRE'E, *Fr.*, the overture to a ballet, and ſometimes the beginning of the dance itſelf. In the firſt operas in France, the overture was called the entrée.

ENTREPAS, in the *Manege*, is a broken pace, or going, properly a broken amble, that is, neither walk nor trot, but has ſomewhat of an amble. This is the pace, or gait, of ſuch horſes as have no reins or backs, and go upon their ſhoulders, or of ſuch as are ſpoiled in their limbs.

ENTREVEAUX, in *Geography*, a ſmall town of France, in the department of the Lower Alps, chief place of a canton in the diſtrict of Caſtellane, with a population of 1326 individuals. It is ſituated at the foot of the Alps, on the river Var, near Glandeves. N. lat. 44° 1′. Its canton has a territorial extent of 197½ kiliometres, eight communes, and 2694 inhabitants.

ENTRICOMA, from εν and θριξ, *hair*, in *Anatomy*, the name of the outer edge of the eye-lid, on which the hairs grow.

ENTRIES, amongſt *Hunters*, thoſe places in thickets through which deer are found lately to have paſſed; by means whereof their bigneſs or ſize is gueſſed at; and at which the hounds or beagles are put to them for the view.

Entries, *Books of*, in *Law*, are ancient and modern, and contain tranſcripts of proceedings that have been had in ſome particular actions; the principal of ſuch are neceſſary for gentlemen educated to the profeſſion of the law.

ENTRING *a Ship*, in *Sea Language*, the ſame with boarding her. See Boarding.

Entring-*Ladder*, in a *Ship*, is of two ſorts; one is uſed by the ſhip's ſides, in a harbour, or in fair weather, for perſons to go in and out of the ſhip: the other is made of ropes, with ſmall ſtaves for ſteps, and is hung out of the galley to enter into the boat, or to come aboard the ſhip from thence, when the ſea runs ſo high that they dare not bring the boat to the ſhip's ſide for fear of ſtaving her. See Gang-way.

Entring-*Ropes*. See Rope.

ENTROCHUS, in *Natural Hiſtory*, the name of a genus of foſſils of a very regular figure and ſtructure, ſuppoſed by many authors to be lapides ſui generis, and ſtones in their native ſtate. They are, however, in reality, the foſſile remains of ſome marine animal, probably either of the echinus, or of the ſtar-fiſh kind, filled like the foſſile ſpecies of the echini, with a plated ſpar. Our imperfect knowledge in the animal hiſtory has not yet been able to aſcertain to what creature they really belong; but their analogy, with the other animal remains, found in the foſſile world, plainly evince, that they are of that origin. They are cylindric columns, uſually about an inch in length, and are made up in a number of round joints, like ſo many ſmall wheels or ſegments of cylinders. Theſe joints, when found ſeparate, and naturally looſe, as they ſometimes are, are called trochitæ. They are all ſtriated, from the centre to the circumference, and have a cavity in the middle, which is ſometimes found empty, but more frequently filled up with various matter, of the nature of the ſtratum, in which they have lain, or of other of the native foſſile ſubſtances.

The entrochi are compoſed of the ſame ſort of plated ſpar with the aſteriæ, and the ſpines and ſhells of the foſſile echini: and this is in theſe uſually of a blueiſh-grey colour, and very bright and gloſſy, where freſh broken. They are ſubject to accidental injuries, like the other extraneous foſſils, which have been formed in animal moulds, and are frequently met with compreſſed, or crooked.

That the entrochi are of marine origin, is evident from this, that they have not unfrequently ſea-ſhells found adhering to them; and when theſe are broken off, there remain on the entrochi no deficiencies, but the ſhells themſelves ſhew that they have been formed upon, and have grown to the entrochi, there being always natural hollows in them to anſwer to that part of the entrochus from which they have been ſeparated; whence it appears very plainly, that theſe entrochi, however altered ſince in their ſubſtance, were, however, exiſting in their preſent ſhape, in thoſe very ſeas where theſe ſhells had their growth.

There are not unfrequently found among the entrochi, larger or ſmaller fragments of plated bodies.

We meet with the entrochi of all the ſizes, from that of a pin's head to a finger's length, and the thickneſs of one's middle finger. They are, in ſome places, found looſe upon ploughed lands; in others, they are lodged in great quantities in the ſtrata of clay, and very often in ſtones of different kinds, and different hardneſs.

Mr. Parkinſon, in his ſecond volume of "Organic Remains," treats very largely of this claſs of animals; and Mr. William Martin, in his recent and valuable work, the "Petrificata Derbienſia," has paid conſiderable attention to the curious remains of this kind which Derbyſhire affords: among which he enumerates, 1ſt, the even-jointed entrochite (Entrochites lævis); 2d, the convex-jointed entrochite (E. prominens); 3d, the warted entrochite (E. verrucoſus); and 4th, the ring-jointed entrochite (E. cannulatus).

Entrochi abound in ſome particular beds of the firſt or upper lime-ſtone rock of the Derbyſhire lime-ſtone or toadſtone ſeries, and from hence the beautiful figured marbles are principally obtained, at Ricklow-dale, Bricks, and High-low, near to Monyaſh; at Foolow, Calver, Lexley in Aſhover, Crick-Cliff, and other places. The three other lime-ſtone rocks, which lie below the above, contain ſome few beds with a ſprinkling of entrochi in them; but they are very inferior in number or ſize to thoſe in the upper rock.

Entrochi are alſo found in ſmall numbers, in the yellow or magneſian range of lime-ſtone, which traverſes the country from Wetherby in Yorkſhire to near Nottingham; appears again at Bredon, Cloud's-hill, Barrow-hill, and Gracedieu in Leiceſterſhire; again at Ruſhall and Walſall; between Wolverhampton and Dudley in Staffordſhire; at Abberley in Worceſterſhire, &c.

The foſſil deſcribed by Mr. Walcot, in his "Petrifications found near Bath," p. 46, under the name of an entrochus, is more properly a trochus or top-ſtone, very different from the entrochi of which we have been ſpeaking: it belongs to the Bath free-ſtone ſtrata.

Entrocho *Aſteriæ*, the name given by authors to a peculiar kind of entrochus, differing from the common kind, in having a ſtellar cavity inſtead of a round one, in its centre.

Entrochus *Pyramidalis*, a name given by ſome writers to the ortho-ceratites, or tubulus marinus concameratus, a ſpecies of ſhell-fiſh, not known to us in its recent ſtate, but very common in the ſtones brought over from Sweden for pavements. Klein. de Tubul. Marin. p. 7. See Tubuli *Concamerati*.

Entrochus *Ramoſus*, the name of a foſſile body, the ſeveral parts of which reſemble the entrochi; but as they are joined together in this body when perfect, they ſhew themſelves in their proper light, and a ſight of them in this ſtate is ſufficient to explode the opinion advanced by ſome perſons, of the entrochi being of a vegetable nature; or, as they have pleaſed to call them, "rock-plants." The foſſil has evidently once been a ſtella-marina, or ſea ſtar-fiſh, conſiſting of twenty rays at the extremity of the body. The manner of inſertion of theſe has been this: the body is of a pentagonal figure, and from this there have ariſen five rays; theſe, at their extremity, have been divaricated, each into two, ſo as to make the number ten in the ſecond progreſſion; and each of theſe laſt being again divaricated into two at its extremity; the third and laſt progreſſion is of twenty rays. All this is eaſily diſtinguiſhable in the foſſil, when perfect, and ſeems to have been the whole figure of the animal while living. The prototype, or living animal, however, is not found; but this is not an accident peculiar to this foſſil, the cornua ammonis, and conchæ anomiæ, with many other bodies that have been once evidently ſhell-fiſh, being no where at this time found in their recent ſtate, though ſo very numerous in the foſſile world. This remarkable foſſile ſtar-fiſh is the body called by ſome authors, lilium lapidium. Keppeler's Epiſt. ad Klein de Entrochis.

ENTROCHORUM Radix. See Radix.

ENTROPIUM, (from εν and τρεπω, *to turn*,) a ſurgical diſeaſe, in which the eyelid turns inward towards the eye, ſo as to occaſion, by the friction and irritation of the eyelaſhes, chronic ophthalmy, and various inconveniences. See Trichiasis.

ENTRUSION, in *Law*. See Intrusion.

ENTRY, or Entrance, in its general ſenſe, denotes a door, gate, paſſage, &c. through which to enter, or arrive within a place.

Entry, in *Book-keeping*. See Book-keeping.

Entry, *Bill of*. See Bill.

Entry, is ſometimes alſo uſed to denote a duty or impoſt laid on commodities imported into a ſtate, either by land or ſea.

The duties of entry, or importation, are paid according to a tariff ſettled for that purpoſe. Where the duty of entry of any commodity is not fixed by the tariff, it is paid by eſtimation, *i. e.* in proportion to what ſome other commodity of nearly the ſame quality and value uſes to pay. In making entries inwards, it is uſual for merchants to include all the goods they have on board the ſame ſhip in one bill, though ſometimes there may happen to be upwards of twenty ſeveral kinds; and in caſe the goods are ſhort entered, additional or port entries are now allowed; though formerly the goods ſo entered were forfeited. As to bills of entry outwards, of including goods to be exported, upon delivering them and paying the cuſtoms, you will receive a cocket, which teſtifies your payment thereof, and of all duties for ſuch goods. If ſeveral ſorts of goods are exported at once, of which ſome are free, and others pay cuſtoms, the exporter muſt have two cockets, and therefore muſt make two entries. Entries of goods, on which a draw-back is allowed, muſt likewiſe contain the name of the ſhip in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken, that the cuſtoms for theſe goods were paid as the law directs; you muſt carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which muſt be given to the ſurveyor, ſearcher, or land-waiter, that they may certify the quantity of goods; after which the certificate muſt be brought back to the collector and comptroller, or their deputies, and oath made, that the ſaid goods are really ſhipped, and not landed again in any part of Great Britain. See Debenture, Importation, and Exportation.

Entry, alſo denotes a ſolemn reception, or a ceremony performed by kings, princes, ambaſſadors, legates, &c. upon their firſt entering a city, or their return in triumph from ſome expedition.

Entry, in *Law*, ſignifies the taking poſſeſſion of lands or tenements by the legal owner, when another perſon, who hath no right, hath previouſly taken poſſeſſion of them. See Possession.

In this caſe the party entitled may make a formal, but peaceable entry thereon, declaring that thereby he takes poſſeſſion; which notorious act of ownerſhip is equivalent to a feodal inveſtiture by the lord (ſee Investiture); or he may enter on any part of it in the ſame county, declaring it to be in the name of the whole (Litt. § 417.); but if it lies in different counties, he muſt make different entries; for the notoriety of ſuch entry or claim to the *pares* or freeholders of Weſtmorland, is not any notoriety to the *pares* or freeholders of Suſſex. Alſo, if there be *two* diſſeiſors, the party diſſeiſed muſt make his entry on *both*; or if *one* diſſeiſor has conveyed the lands with livery to *two* diſtinct feoffees, entry muſt be made on *both* (Co. Litt. 252.); for as their *ſeiſin* is diſtinct, ſo muſt alſo be the act which diveſts that ſeiſin. If the claimant be detained from entering by menaces or bodily fear, he may make *claim*, as near to the eſtate as he can, with the like forms and ſolemnities; which claim is in force for only a year and a day. (Litt. § 422.) And this claim, if it be repeated once in the ſpace of every year and day (which is called *continual claim*) has the ſame effect with, and in all reſpects amounts to, a legal entry. (Litt. § 419, 423.) Such an entry gives a man ſeiſin, (Co. Litt. 15.) or puts into immediate poſſeſſion him that hath right of entry on the eſtate, and thereby makes him complete owner, and capable of conveying it from himſelf by either deſcent or purchaſe. This remedy by entry takes place in three only of the five ſpecies of ouſter, *viz.* abatement, intruſion, and diſſeiſin (Co. Litt. 237, 238.); for as in theſe the original entry of the wrong-doer was unlawful, they may therefore be remedied by the mere entry of him who hath right. But, upon a diſcontinuance or deforcement, the owner of the eſtate cannot enter, but is driven to his action; for herein the original entry being lawful, and thereby an apparent right of poſſeſſion being gained, the law will not ſuffer that right to be overthrown by the mere act or entry of the claimant. Yet a man may enter on his tenant by ſufferance; for ſuch tenant hath no freehold, but only a bare poſſeſſion; which may be defeated, like a tenancy at will, by the mere entry of the owner. But if the owner thinks it more expedient to ſuppoſe or admit ſuch tenant to have gained a tortious freehold, he is then remediable by writ of entry, *ad terminum qui præteriit*. (Co. Litt. 57.) On the other hand, in caſe of abatement, intruſion, or diſſeiſin, where entries are generally lawful, this right of entry may be *tolled*, that is, taken away by deſcent. Deſcents, which take away entries (Litt. § 385—413.) are, when any one, ſeiſed by any means whatſoever of the inheritance of a corporeal hereditament, dies, whereby the ſame deſcends to his heir; in this caſe, however feeble the right of the anceſtor might be, the entry of any other perſon who claims title to the freehold is taken away; and he cannot recover poſſeſſion againſt the heir by this ſummary method, but is driven to his action to gain a legal ſeiſin of the eſtate. In general it appears, that no man can recover poſſeſſion by mere entry on lands, which another hath by deſcent. And this title of taking away entries by deſcent is ſtill further narrowed by the ſtatute 32 Hen. VIII. c. 13. which enacts, that if any perſon diſſeiſes, or turns another out of poſſeſſion, no deſcent to the heir of the diſſeiſor ſhall take away the entry of him that has right to the land, unleſs the diſſeiſor had peaceable poſſeſſion five years next after the diſſeiſin. But the ſtatute extendeth not to any feoffee or donee of the diſſeiſor, mediate or immediate. (Co. Litt. 246. 256.) By the ſtatute of limitations it is enacted by ſtatute 21 Jac. I. c. 16, that no entry ſhall be made by any man upon lands, unleſs within 20 years after his right ſhall accrue: and by ſtatute 4 and 5 Ann. c. 16, no entry ſhall be of force to ſatiſfy the ſaid ſtatute of limitations, or to avoid a fine levied of lands, unleſs an action be thereupon commenced within one year after, and proſecuted with effect. Moreover, this remedy by entry muſt be purſued, according to ſtatute 5 Ric. II. ſt. 1. c. 8. in a peaceable and eaſy manner; and not with force or ſtrong hand. For, if one turns or keeps another out of poſſeſſion forcibly, this is an injury of both a civil and criminal nature. The civil is remedied by immediate reſtitution; which puts the ancient poſſeſſor *in ſtatu quo*; the criminal injury, or public wrong, by breach of the king's peace, is puniſhed by fine to the king. Blackſtone's Comm. b. iii. See FORCIBLE *Entry*.

ENTRY, *writ of*, is a poſſeſſory remedy, which diſproves the title of the tenant or poſſeſſor, by ſhewing the unlawful means by which he entered or continues poſſeſſion. (Finch. L. 261.) This writ is directed to the ſheriff, requiring him to "command the tenant of the land that he render (in Latin, *præcipe quod reddat*) to the demandant the land in queſtion, which he claims to be his right and inheritance; and into which, as he ſaith, the ſaid tenant had not entry but by (or after) a diſſeiſin, intruſion, or the like, made to the ſaid demandant, within the time limited by law for ſuch actions; or that upon refuſal he do appear in court on ſuch a day, to ſhew wherefore he hath not done it. This is the original proceſs, the *præcipe*, upon which all the reſt of the ſuit is grounded; wherein it appears, that the tenant is required, either to deliver ſeiſin of the lands, or to ſhew cauſe why he will not. This cauſe may be either a denial of the fact, of having entered by or under ſuch means as are ſuggeſted, or a juſtification of his entry by reaſon of title in himſelf, or in thoſe under whom he makes claim; whereupon the poſſeſſion of the land is awarded to him who produces the cleareſt right to poſſeſs it.

Writs of entry are of divers kinds, diſtinguiſhed into four degrees, according to which the writs are varied. The *firſt* degree is a writ of entry *ſur diſſeiſin*, that lieth for the diſſeiſee againſt a diſſeiſor, upon a diſſeiſin done by himſelf; and this is called a writ of entry in the nature of an aſſiſe. The *ſecond* degree, by ſome reckoned the firſt, is a writ of entry *ſur diſſeiſin in le per* and lies againſt the heir by deſcent, who is ſaid to be in the *per*, as he comes in by his anceſtor; and ſo it is if a diſſeiſor make a feoffment in fee, gift in tail, &c. The feoffee and donee are in the *per* by the diſſeiſor. The *third* is a writ of entry *ſur diſſeiſin in le per and cui*, where the feoffee of a diſſeiſor maketh a feoffment over to another; when the diſſeiſee ſhall have this writ of entry ſur diſſeiſin, &c. of the lands in which ſuch other had no right of entry, but by the feoffee of the diſſeiſor, to *whom* the diſſeiſor demiſed the ſame, who unjuſtly and without judgment diſſeiſed the demandant. (1 Inſt. 238.) Theſe three degrees thus ſtate the original wrong, and the title of the tenant who claims under ſuch wrong. If more than two degrees (that is, two alienations or deſcents) were paſt, there lay no writ of entry at the common law. For, as it was provided, for the quietneſs of men's inheritances, that no one, even though he had the true right of poſſeſſion, ſhould enter upon him who had the apparent right by deſcent or otherwiſe, but he was driven to his *writ of entry* to gain poſſeſſion; ſo, after more than two deſcents or conveyances were paſſed, the demandant, even though he had the right both of poſſeſſion and property, was not allowed this *poſſeſſory* action, but was driven to his *writ of right*, a long and final remedy, to puniſh his neglect in not ſooner putting in his claim, while the degrees ſubſiſted, and for the ending of ſuits, and quieting of all controverſies. (2 Inſt. 153.) But by the ſtatute of Marlbridge, 52 Hen. III. c. 30, it was provided, that when the number of alienations or deſcents exceeded the uſual degrees, a new writ ſhould be allowed without any mention of degrees at all. Accordingly a new writ, or a *fourth*, has been framed, called a writ of entry in the *poſt*, which only alleges the injury of the wrong-doer, without deducing all the intermediate title from him to the tenant; ſtating it in this manner; that the tenant had not entry unleſs *after*, or ſubſequent to, the ouſter or injury done by the original diſpoſſeſſor; and rightly concluding, that if the original title was wrongful, all claims derived from thence muſt participate of the ſame wrong. Upon the latter of theſe writs it is (the writ of entry *ſur diſſeiſin* in the *poſt*) that the form of our common recoveries of landed eſtates is uſually grounded. See FINE and RECOVERY.

This remedial inſtrument of writ of entry is applicable to all the caſes of ouſter (ſee OUSTER), except that of diſcontinuance by tenant in tail, and ſome peculiar ſpecies of deforcements. Such is that of deforcement of dower, by not aſſigning *any* dower to the widow within the time limited by law; for which ſhe has her remedy by writ of *dower, unde nihil habet*. (F. N. B. 147.) See DOWER. But in general the writ of entry is the univerſal remedy to recover poſſeſſion, when wrongfully withheld from the owner. It would, therefore, be endleſs to recount all the ſeveral diviſions of writs of entry, which the different circumſtances of the reſpective demandants may require, and which are furniſhed by the laws of England. (See Bracton, l. 4. tr. 7. c. 6. § 4. Britton, c. 114. fol. 264.) Of theſe the moſt uſual were, 1. The writ of entry *ſur diſſeiſin*, and of intruſion (F. N. B. 191. 203.), which are brought to remedy either of the ſpecies of ouſter. 2. The writs of *dum fuit infra ætatem*, and *dum fuit non compos mentis* (Ibid. 192. 202.) which lie for a perſon of full age, or one who hath recovered his underſtanding, after having, (when under age or inſane,) aliened his lands; or for the heirs of ſuch alienor. 3. The writs of *cui in vita*, and *cui ante divortium* (Ibid. 193. 204.) for a woman, when a widow or divorced, whoſe huſband during the coverture hath aliened her eſtate. 4. The writ *ad communem legem* (Ibid. 207.) for the reverſion, after the alienation and death of the particular tenant for life. 5. The writs *in caſu proviſo*, and *in conſimili caſu*, (Ibid. 205, 206.) which lay not *ad communem legem*, but are given by ſtat. Gloc. 6 Edw. I. c. 7. and Weſtm. 2. 13 Edw. I. c. 24, for the reverſioner after the alienation, but during the life of the tenant in dower or other tenant for life. 6. The writ *ad terminum qui præteriit* (Ibid. 201.) for the reverſioner, when the poſſeſſion is withheld by the leſſee or a ſtranger, after the determination of a leaſe for years. 7. The writ *cauſa matrimonii prælocuti* (Ibid. 205.) for a woman who giveth land to a man in fee or for life, to the intent that he may marry her, and he doth not: and the like in caſe of other deforcements. Theſe writs are plainly and clearly chalked out in that moſt ancient and highly venerable collection of legal forms, the "regiſtrum omnium brevium," or regiſter of ſuch writs as are ſueable out of the king's courts, upon which Fitzherbert's "Natura Brevium" is a comment.

In the times of our Saxon anceſtors, the right of poſſeſſion ſeems only to have been recoverable by writ of entry (Gilb. Ten. 42.); which was then uſually brought in the county-court. The proceedings in theſe actions were not then ſo tedious, when the courts were held, and proceſs iſſued from and was returnable therein at the end of every three weeks, as they became after the conqueſt, when all cauſes were drawn into the king's courts, and proceſs iſſued only from term to term, which was found exceedingly dilatory, being at leaſt four times as ſlow as the other. Hence a new remedy was invented, in many caſes, to do juſtice to the people and to determine the poſſeſſion in the proper counties, and yet by the king's judges. This was the remedy by *aſſiſe*, which ſee. Blackſt. Comm. b. iii. For other particulars on the ſubject of this article, ſee Jacob's Law Dict. by Tomlins.

Entry *Iſland*, in *Geography*, one of the Magdalen iſlands in the gulf of St. Lawrence. N. lat. 46° 18'. W. long. 61° 20'.—Alſo, an iſland in the Pacific ocean, about nine leagues N. from Cape Tierawite and under the ſame ſhore, which may be diſtinctly ſeen from Queen Charlotte's Sound, at the diſtance of about ſix or ſeven leagues. The name was given to it by lieutenant Cook, who paſſed it in January 1770.

ENTYPOSIS, from ἐντυπόω, *I make an impreſſion*, in *Anatomy*, the articulation of the ſhoulder with the arm.

ENTZERSTORFF, in *Geography*, a town of Germany, in the archduchy of Auſtria; ſix miles S. of Laab.—Alſo, a town of Germany, near the conflux of the rivers Reſtinpach and Reiſenpach; 10 miles W.N.W. of Bruck.

Entzerstorff in *Logenthal*, a town of Germany, in the archduchy of Auſtria; two miles S.E. of Corn Neuburg.

Entzerstorff or *Statl-Entzerſtorff*, a caſtellated town of Germany, in the archduchy of Auſtria, on the north ſide of the Danube, belonging to the biſhop of Freyſingen; 24 miles W. of Preſburg and nine E. of Vienna.

ENVERMEU, a ſmall town of France, in the department of the Lower Seine, chief place of a canton in the diſtrict of Dieppe, with a population of 896 individuals. The canton contains 40 communes and 13,402 inhabitants, on a territorial extent of 265 kiliometres.

ENVELOPE, in *Fortification*, denotes a mount of earth ſometimes raiſed in the ditch of a place, and ſometimes beyond it, being either in form of a ſimple parapet, or of a ſmall rampart bordered with a parapet.

Theſe envelopes are made where weak places are only to be covered with ſingle lines, without advancing towards the field, which cannot be done but by works which require a great deal of room: ſuch as horn-works, half-moons, &c. Envelopes are ſometimes called ſillons contregards, conſerve, lunettes, &c.

ENVIRON, among *Military Men*, relates to that complete inveſtment of a town, or fortreſs, which utterly precludes the acquiſition of ſupplies, or of reinforcements, and, in a general ſenſe, may be ſaid to be the baſis of a blockade. When we ſay that a place is environed, we are not indiſcriminately to conclude, that any circumvallation has taken place; but, that the country round is ſo completely poſſeſſed by the enemy, as to render any attempt to afford ſuccour to the inhabitants unavailing. Thus, if there be ſeveral paſſes leading to a town ſituated in a valley, ſurrounded by mountains inacceſſible, or impaſſable in every part, except at thoſe paſſes; or if a town ſtands on a peninſula, of which the iſthmus is cut off by the enemy, who likewiſe poſſeſs the navigation of the circumferent waters, ſuch towns are, to all intents and purpoſes, environed; and, if the blockade be duly ſupported, muſt in time ſurrender merely from a want of ſupplies.

If, however, the enemy ſhould not be ſtrong enough to keep the inhabitants within cloſe bounds, or if, notwithſtanding the whole of the adjacent country may be under his controul, ſupplies may be attainable from the exterior, whether by connivance among the peaſantry, or by the operations of enterpriſing partizans, then the place cannot be ſaid to be environed. When we conſider the many chances ariſing in favour of ſuch garriſons as make a good defence, it ſhould appear to be the beſt policy, as well as the moſt honourable conduct, to hold out to the very utmoſt, and never to ſurrender except under the laſt extremity. As to being environed, or blockaded, it is ſometimes a very important advantage gained by the defending power, becauſe it muſt prove a complete diverſion, by cauſing a very large force to be occupied in ſhutting up a comparative hand-full.

It, however, very rarely happens, that towns are, properly ſpeaking, environed: the old ſyſtem of circumvallation is now obſolete, except in very confined caſes, and where there is no army in the field capable of raiſing the ſiege. We have, indeed, a recent inſtance of a large city, namely, Saragoſſa, having been environed; but it was under moſt peculiar circumſtances; for the place fell rather from a want of an adequate force to cope internally with the aſſailants, though, on the other hand, the want of ſupplies was ſeverely felt. If any thing could ſtrengthen the recommendation we have juſt given, of continuing a defence to the laſt moment, ſurely the noble example ſhewn by that loyal and illuſtrious, but moſt unfortunate city, muſt ſerve as a ſtimulus, and prompt every perſon in charge of a beſieged fortreſs, or town, to deſpiſe the efforts of the environing army, and to ſell every inch of ground at the higheſt price that valour can impoſe on a ſuperior force.

Thoſe who undertake a blockade, by completely environing a town, &c. have a moſt arduous taſk to perform. They have not only to oppoſe the ſallies of the garriſon, but to keep a very ſharp look-out againſt exterior attacks, which may often be ſo effectually made, by an enterpriſing partizan, as to coerce a very numerous army to conſiderable relaxation, ſuch, indeed, as muſt prove favourable to the defenders. When we conſider theſe circumſtances, we ſhall be leſs ſurpriſed at the great loſſes ſuſtained by beſiegers, who, as well as the beſieged, ſuffer under all the diſadvantages attendant upon fixed camps; whereby not unfrequently the moſt deſtructive diſeaſes are engendered.

ENVIRONNE', in the *French Heraldry*, is when a lion or other figure is environed, or encompaſſed round with other things. Environné with ſo many bezants, &c. in orle.

ENULA, in *Botany*. See Inula.

ENULION, from ἐν and οὖλον, the *gums*, a word uſed by ſome medical writers for the fleſh of the gums.

ENUMERATION, the act of enumerating, or counting. At the time of our Saviour's birth, Auguſtus Cæſar had commanded an enumeration to be made of all the world, or rather of all the people under his empire: though ſeveral able authors are of opinion, that the cenſus, tax, or enumeration mentioned by St. Luke, did not extend to the whole empire, but only to the people of Judæa. See Perizonius de Cenſu Judaico, and Berger de Viis Militaribus.

At Rome, it was an uſual thing to have an enumeration made of all the families: the firſt of theſe was under Servius Tullius, when the men amounted to eighty thouſand. Pompey and Craſſus made another, when they reached to four hundred thouſand. That of Cæſar did not exceed one hundred thouſand; ſo that the civil wars muſt have deſtroyed three hundred thouſand Roman citizens. Under Auguſtus, in the year 725, the Roman citizens throughout the empire were numbered at four millions ſixty-three thouſand. In the year of Rome 746, the citizens, being numbered again, were found four millions two hundred and thirty-three thouſand. In the year 766, being the laſt year of Auguſtus's reign, that prince, together with Tiberius, made another enumeration of the citizens of Rome, when they were found four millions one hundred and thirty-ſeven thouſand perſons.

Claudius made a new computation in the year of Chriſt 48, when, as Tacitus relates it, the Roman citizens throughout the whole empire amounted to ſix millions nine hundred and ſixty-four thouſand; though others repreſent the number as conſiderably greater. A very rare, yet indiſputable medal of Claudius, never yet made public, expreſſes the preciſe number in this liſt made by Claudius, which was called oſtenſio, to be ſeven millions of people fit to bear arms, beſide all the ſoldiers on foot in the armies, which amounted to fifty legions, fifty-ſeven cohorts, and ſixty ſoldiers. After this enumeration, we find no more till that of Veſpaſian, which was the laſt.

ENUMERATION, in *Rhetoric*, denotes a part of the peroration, wherein the orator, collecting the ſcattered heads of what has been delivered throughout the whole, makes a brief and artful rehearſal or recapitulation thereof. See RECAPITULATION.

ENUMERATION is alſo a rhetorical figure: for which ſee APARITHMESIS.

ENUMERATION *of the parts*, amounts to the ſame with what we more uſually call diſtribution. In this part of rhetoric, the orator acquaints his hearers with the ſeveral parts of his diſcourſe, upon which he deſigns to treat. See DISTRIBUTION and PARTITION.

ENUNCIATION, a ſimple expreſſion or declaration of a thing, in terms either of affirmation or denial.

The ſchoolmen uſually diſtinguiſh three operations of the underſtanding; apprehenſion, enunciation, and reaſoning.

ENUNCIATION, among *Logicians*, denotes the ſame as propoſition.

ENUNCIATION, which, without violation of etymology, might be applied to ſignify the whole act of ſpeech or delivery of language, is, in conformity with the theory and ſyſtem laid down under the article ELOCUTION, confined to the utterance and combination of the elements, and the conſequent pronunciation of ſyllables, words, &c. as contradiſtinguiſhed from the tones, and tuning of the voice, and all that belongs to the melody of ſpeech.

The perfection of enunciation conſiſts in the following particulars; 1. *Diſtinctneſs*, or the clear and perfect formation of the reſpective elements by right motions and poſitions of the organs of the mouth, accompanied by proper degrees of energy and impulſe to impreſs thoſe elements fully and contradiſtinctly on the ear. 2. *Articulation*, or the act of combining and linking together of the reſpective elements, ſo as to form them into intelligible ſyllables and words, capable of being again combined into clauſes and ſentences for the proper conveyance of our ideas, thoughts, and determination. 3. *Implication*, or the combination and apparent union of words in oral utterance, which are graphically ſeparated; and by which, without injury to the intelligible diſtinctneſs of the reſpective words, all differences of auditory impreſſions are removed between monoſyllabic and polyſyllabic compoſition in language.

The faults immediately oppoſed to diſtinctneſs are, 1. *Mumbling*, or an indolence or want of preciſion in the action of the lips, affecting, of courſe, principally the labial ſounds, but impeding, to a certain degree, the clear progreſs of the ſpecific impulſes given to other elements, by the interior organs of the mouth. 2. *Thickneſs*, or indolence and imperfection in the action of the tongue, and affecting, more or leſs, the whole or part of the lingual ſounds. 3. *Drawling*, which reſults from indolence or inaptitude of the whole organs of ſpeech, vocal as well as enunciative. Theſe are defects of lethargy, or deficiency of organic action. Thoſe that follow are of another deſcription. 4. *Mouthing*, a pompous but dull ſpecies of indiſtinctneſs, which reſults from affectedly purſing up the mouth, and conſequent drawing the cheeks too cloſe upon, or even between the teeth, during the act of ſpeaking: it is one of the unſucceſsful theatrical means of aiming at ſublimity and pathos. 5. *Cluttering*, a ſpecies of St. Vitus's dance of the organs; hurrying them with too much rapidity and indeciſion from one elementary poſition to another, before the reſpective elements are completely formed, or have had time to make their reſpective impreſſions diſtinctly on the ear. This laſt is one of the fruitful ſources of impediment of ſpeech.

The faults oppoſed to articulation and implication are, a *fau-ul-ter-r-ring he-e-ſi-i-ta-a-tion*, a *púl,ſá,tive ín,tér, rúp,tion*, (ſuch as is almoſt univerſally obſervable in the early reading of ſchool boys, and which ſome people in their reading never get rid of as long as they live,) and a pè-dán-tìc fòr-má-lì-ty', ſuch as was ridiculed in a gentleman, who, aſking his friend if he came to town in his *cha-ri-ot*, was anſwered, no, ſir, I came in my *co-ach*. But the contradiſtion, and even oppoſition, thus marked between diſtinctneſs and articulation, though ſo indiſpenſible to the intelligible treatment of the ſubject of elocutionary ſcience and inſtruction, is ſo little authorized by thoſe who have hitherto treated upon theſe ſubjects, that the writer of this article deems it neceſſary controverſially to refer to thoſe authorities, and to ſtate the objections to the cuſtomary and confuſed phraſeology which they have ſanctioned. Among theſe, ſome have defined the term articulation as if it embraced the whole art and practice of enunciative utterance, as the ingenious, and generally ſpeaking, profound and accurate Mr. Gough,—"Articulation," ſays he, "is the art of modifying the ſounds of the larynx by the aſſiſtance of the cavity of the mouth, the tongue, teeth, and lips." (Manch. Mem. vol. v. pt. ii. p. 645.) But much more frequently it is uſed as a pure ſynonym with *diſtinctneſs*. (Mr. Sheridan, in his lectures, confounds it not only with diſtinctneſs but with enunciation generally, and even with idiomatic pronunciation, Lect. ii. p. 21. 8vo. edit.) But, not to inſiſt particularly upon the important axiom, that the very admiſſion of ſynonyms is inconſiſtent with the progreſs and communication of ſcientific truth, if ſuch were the uſe to which the term articulation were to be applied, why did the Engliſh grammarian go to the Greek language and to the ſcience of anatomy to borrow a name for an idea which he had already a good and familiar Engliſh word fully and completely to convey? How came he to apply that word ſo ſuperfluouſly borrowed in a ſenſe diametrically oppoſite to that which it bears in the ſcience from which it is taken? For articulation in anatomy ſignifies the *juncture of bones*, or that flexible combination of joints or elementary portions into a limb, or of limbs into a body, by which the unity of the whole is conſtituted, without injury to the individuality of the parts. And laſtly, how came he to look out for a ſupernumerary name to one idea, while another idea equally indiſpenſible to his ſcience (for the combination of elements is as neceſſary to ſpeech as their formation) without any ſeparate or ſpecific deſignation? Without going further, therefore, into critical diſquiſition, we may venture to lay down, as one of the canons of elocution and grammatical nomenclature, the following definition.—Articulation (as one of the eſſential properties of human enunciation, is the jointing or linking together of the reſpective elements, and ſyllables, and words (the portions, limbs, and members of ſentences) as the bones themſelves, (the portions, limbs, and members of the anatomical frame) are linked or jointed together, by an analogous articulation in animal economy. Implication will then remain to be conſidered merely as that part of articulation which relates ſeparately to the articulation of ſeparate graphic words in the act of oral delivery, and conſequently as indicating rather a grammatical diſtinction, than a diſtinct ſpecies or modification of organic action: for in well delivered ſpeech (it is contended, by the authority ſo frequently referred to in the different articles relative to elocution) the ear, unaſſiſted by the memory of the eye, knows of no ſuch thing as a diviſion or diſtribution of ſpeech into ſuch ſeparable portions as in graphic compoſition are denominated words. The proceſs of enunciation and implication conſiſts in a delicate preciſion of the motion of the organs, without ceſſation of ſound, from one elementary poſition to another, by which the termination of the perfect ſound is glided more or leſs intimately into the ſucceeding element or commencement of the enſuing ſyllable. Thus literal ſounds, intimately glided into each other, are articulated into ſyllables; as, *a* and long *l* into *all*. Syllabic ſounds, intimately glided into each other, are articulated into words; as, *all* and *ways* into *always*. The terminations of words (as they are called in conformity with graphic diſtinctions) glided into the initial ſounds of ſucceeding words, are implicated into clauſes, or parts of clauſes; as

the man, a ſhip, an apple,

Harry to Harry might, and horſe to horſe, &c.

A good enunciation, then, conſiſts in that clear and accurate delivery of verbal language, by which the requiſite qualities of diſtinctneſs and articulation are combined and modified; and the due proportions and alterations of ſound and interruptions, conſtituting the ſpecific relations of letters, ſyllables, members, clauſes, and ſentences, are preſerved in diſcourſe or reading.

ENUNCIATIVE Organs, thoſe portions and members of the human mouth, by the motions, poſitions, and contact of which, ſpecific character is ſuperadded to the original impulſes of voice, ſo as to render them communicable ſigns of diſtinct ideas. See Organs *of Speech*.

ENVOICE. See Invoice.

ENVOY, a public miniſter ſent by one ſovereign prince or independent ſtate to another to negociate ſome affair, or to watch over the intereſts of that ſtate or prince in general, and furniſhed with the credentials of an envoy. Like embaſſadors, envoys may be either *ordinary*, who reſide permanently at the court of a foreign prince, or *extraordinary*, who are diſpatched for one particular purpoſe, and retire when their miſſion is accompliſhed. Envoys hold the ſecond rank among public miniſters ſent to foreign courts: but they are alike under the ſpecial protection of the law of nations, and enjoy all the privileges and immunities of embaſſadors, except thoſe relating to the ceremony of their reception, public entry, and ſolemnity of their audiences. See Embassador.

The quality of envoy extraordinary, Wicquefort obſerves, is very modern; more modern than that of reſident: the miniſters inveſted therewith, at firſt, took on them moſt of the airs of embaſſadors; but they have ſince been taught otherwiſe.

In the year 1639, the court of France made a declaration, that the ceremonies of conducting envoys extraordinary to their audience in the king and queen's coaches, with divers others, ſhould no longer be practiſed to envoys.

S. Juſtiniani, the firſt envoy extraordinary from Venice, after that regulation, offered to cover in ſpeaking to the king, but it was refuſed him; and the king of France himſelf declared, that he did not expect his envoy extraordinary at the court of Vienna ſhould be regarded any otherwiſe than as an ordinary reſident. Since this time, thoſe two kinds of miniſters have been treated alike. Wicquefort.

ENURE, in *Law*, ſignifies to take place, or be available, and is as much as to have effect. Thus for inſtance, a releaſe made to tenant for life ſhall enure, and be of force and effect to him in the reverſion.

ENURESIS, in *Medicine*, from ἐν and οὔρησις, *mingendi actus*, the noſological term for incontinence of the urine. See Urine, *incontinence of*.

ENVY, in *Ethics*, is defined by Mr. Locke to be an uneaſineſs of mind, occaſioned by the conſideration of a good we diſcover in poſſeſſion of another perſon, whom we deem leſs worthy of it than ourſelves. It is a compoſition of ſorrow and hatred, and ſtands in direct oppoſition to congratulation. Otherwiſe, envy entertains a degree of ſorrow that the good contemplated ſhould eſcape ourſelves, and of anger that it ſhould fall to the ſhare of another. Or, it is that ſpecies of malevolence which is inſpired by the conjoined influence of pride, ſorrow, and anger. It differs from *emulation* (which ſee), or a diſquiet, occaſioned by the felicity of another, not becauſe he enjoys it, but becauſe we deſire the like for ourſelves; as it occaſions an uneaſineſs not merely from the want of the felicity poſſeſſed by another, but becauſe he enjoys it. Envy, in its nature and effects, is the baſeſt, moſt miſchievous, and moſt tormenting of all paſſions. Ariſtotle (De Rhetor. l. ii. c. 12.) obſerves, that this paſſion moſt uſually affects perſons who were once upon a level with thoſe they envy. The method preſcribed by Cicero (De Orat. l. ii. c. 52.) for leſſening or removing the influence of this paſſion is to ſhew that the things which occaſioned it, have not happened to the envied perſon undeſervedly; but are the juſt rewards of his induſtry or virtue; that he does not ſo much convert them to his own profit or pleaſure, as to the benefit of others; and that the ſame pains and difficulties are neceſſary to preſerve them, with which they were at firſt acquired.

Envy, in *Mythology*, is repreſented by the Greek and Roman poets as an infernal divinity, with ſquinting eyes, lean body, pale countenance, diſturbed air, head encompaſſed with ſerpents, &c.

ENURNY, is the *herald's* term for the bordure of a coat of arms being charged with any kind of beaſts.

ENXYLON, of εν and ξυλον, *wood*, a name uſed by the Greek authors for a ſpecies of worm or maggot, hatched from the egg of a beetle, and having its habitation in wood: which, in this ſtate, it erodes and burrows into, in various directions. The old Greeks called it alſo *dex* and *thrips*, and uſed the pieces of wood eroded by it in remarkable figures, as ſeals. See Thrips.

ENY, Saint, in *Geography*, a ſmall town of France, in the department of La Manche; 9 miles S. W. of Carentan.

ENYDRA, in *Botany*, (ενυδρος, *living in the water*,) a Syngeneſious genus of Loureiro's Fl. Cochinch. 510, which appears to belong to the 4th ſection of Juſſieu's *Corymbiferæ*, and to the order *Polygamia-ſegregata* of Linnæus. The character is, Common Calyx of four leaves; partial of one leaf, rolled up into a tube, ſingle-flowered. Corollets all tubular; thoſe of the radius three-cleft. Receptacle naked. Down none. The ſpecies is E. *fluctuans*, a native of the marſhes of Cochinchina, with oppoſite, ſerrated, rather haſtate leaves, and a white terminal flower. We know not whether it be reducible to any previouſly-deſcribed genus.

ENYSTRON, of εν and ὕστερος, *poſterior*, a word uſed by Ariſtotle for the ſecond ventricle in ruminating quadrupeds, in which the food is elaborated and concocted.

ENZ, in *Geography*, a river of Germany, which riſes about 10 miles W. of Altenſtadt, in the circle of Swabia, paſſes by Wildbad, Neuenburg, Pfortzheim, &c., and joins the Neckar at Beſſigheim, in the duchy of Wurtemberg.

ENZELLI. See Einzellee.

ENZIG, a lake of Germany, in the circle of Upper Saxony, and new mark of Brandenburg; 12 miles W.S.W. of Dramberg.

ENZINAS, Francis, in *Biography*, was born at Burgos, in Spain, about the year 1515. In Moreri and other works he is known by the name of Dryander, which is a Greek tranſlation of his family name. He was educated in Germany, and became a zealous diſciple of Melancthon, who thought very highly of his talents, and wrote a letter in his favour to archbiſhop Cranmer in the year 1548. He publiſhed a Spaniſh tranſlation of the New Teſtament, which he dedicated to the emperor Charles V.; and which drew down upon him the vengeance of the higher powers, and he ſuffered an impriſonment of 15 months duration. He eſcaped in the year 1545, and went to Calvin, who reſided at Geneva. He publiſhed "A hiſtory of the State of the Low Countries, and of the Religion of Spain," which is very rare, and forms a part of the "Proteſtant Martyrology," printed in Germany.

Enzinas, John, brother of the former, reſided a conſiderable time at Rome, and became a convert to the proteſtant religion, and was ſetting out for Germany to join his brother John, when ſome expreſſions which he dropped, relative to the corruptions and diſorders of the church, occaſioned his being accuſed of hereſy, and thrown into priſon. The terrors of a dungeon, and the proſpect of a cruel death, did not daunt his noble ſoul, but when brought before the pope and cardinals to be examined, he refuſed to retract what he had ſaid, and boldly avowed and juſtified his opinions, for which he was condemned to be burnt alive; a ſentence which was put into execution at Rome in the year 1545. Moreri, under the word Dryander.

ENZOWAN, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; four miles E. of Leitmeritz.

EO, Eu, or *Miranda*, a river of Spain, which riſes in the mountains of Aſturias, ſeparates the province of Aſturias from Galicia, and runs into the Atlantic, a little to the north of Rivadeo.

EOA, in *Ancient Geography*, a town of Africa Propria, according to Ptolemy; called Oea by Mela.

EOBANUS, Helius, in *Biography*, an eminent Latin poet, was born, in 1488, on the confines of Heſſe; hence he obtained the name of Heſſus. His parents were ſo poor, that it has been ſaid he was born in the open air under the ſhade of a wide ſpreading tree; but his education was not neglected. He was taught Latin at a ſmall ſchool, and purſued his more advanced ſtudies at the univerſity of Erfurt, where he afterwards taught the belles lettres till the year 1526, when Philip Melancthon procured him an invitation from the city of Nuremberg. Here he taught for ſeven years and then returned to Erfurt, where his reputation was ſo high and ſo firmly eſtabliſhed, that he is ſaid to have had 1500 ſcholars at a time. His fame produced him but very trifling emoluments, and he was often labouring under the greateſt poverty. He at length obtained through the intereſt of Philip, landgrave of Heſſe, a good ſituation at the univerſity of Marpurg, where he died on the 5th of October 1540. Camerarius, who wrote his life, praiſes his good qualities, his application to labour, and his talent at poetry. He was a man of great good nature, ſincere in his attachments, and averſe from contention. He took credit to himſelf for being a hard drinker, and would challenge any man as to the quantity of liquor which he would drink, and in a conteſt of this kind his antagoniſt fell dead on the floor. He wrote many books, a liſt of which is given by Moreri: his poems and epiſtles have been frequently publiſhed. Moreri.

EODANDA, in *Ancient Geography*, a deſert iſland, ſituated E. of Arabia Felix.

EOLIAN, in *Ancient Muſic*. The Eolian tone or mode was one of the mean or principal modes of the Greek muſic, and its fundamental ſound was immediately above the Phrygian.

The Eolian mode was grave, according to Laſus. "I ſing (ſays he) Ceres and her daughter Melibæa, the ſpouſe of Pluto, upon the Eolian mode, full of gravity."

The name of Eolian, given to this mode, is not derived from the Eolian iſles, but from Eolia, a country of Aſia Minor, where it was firſt uſed.

EOLIC, or rather *Æolic*. See Æolic.

EOLIPILE. See Æolipile.

EOLUS, and Eolus's *harp*. See Æolus.

EON, or Æon. See Æon.

Eon, a word uſed by ſome anatomical writers to expreſs the whole ambit or compaſs of the eye.

Eon, de l'Etoile, in *Biography*, a French fanatic, who, from the reſemblance of his name to the word *eum*, applied to himſelf this paſſage, "per Eum qui venturus eſt judicare vivos et mortuos," and was ſatisfied that he was the perſon alluded to, *viz.* the ſon of God. This doctrine he taught with much fervour, and ſucceeded, like other enthuſiaſts, in making many converts, who gave him the homage due to one on whom their future deſtiny depended. At Rheims he drew down the notice of the clergy, who cauſed him to be apprehended, and after an examination he was committed to priſon, where he languiſhed a few days, and miſerably died. Many of his adherents perſiſting in the ſame follies which had characterized their maſter, were apprehended, and, refuſing to abjure their errors, were delivered over to the ſecular power, and were burnt alive in the neighbourhood of Rheims. Such was the perſecuting ſpirit of the prieſts who never fail to abuſe the power entruſted to them, and who would, in this inſtance, have been better employed in inſtructing their own flocks than in murdering theſe deluded fanatics. Moreri.

EOOA. See Ea-oo-wee.

EORDÆA, in *Ancient Geography*, a country of Macedonia, in Mygdonia.

EORIA, in *Mythology*, a feaſt celebrated by the Athenians in honour of Erigonus, who, by way of puniſhment, for their not avenging the death of his father Icarus, engaged the gods to inflict the curſe on their daughters, that they ſhould love men who never returned their paſſion. The feaſt was inſtituted by the order of Apollo.

EOSTRE, a Saxon goddeſs, to whom they ſacrificed in the month of April, called the month of Eoſtra; and thence the name Eaſter, which the Saxons retained after their converſion to Chriſtianity, applying it to the feſtival celebrated in commemoration of our Saviour's reſurrection. Bed. de Rat. Temp. cap. 13.

EPACRIA, in *Ancient Geography*, a town of Greece, in Attica.

EPACRIS, in *Botany*, from επι, *upon*, and ακρις, *the ſummit of a mountain*, alluding to the native ſituation of ſeveral of the ſpecies. Mountain-bloſſom. Forſt. Gen. t. 10. Linn. Suppl. 19. Schreb. 113. Willd. Sp. Pl. v. 1. 834. Mart. Mill. Dict. v. 2. Gærtn. t. 94. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Ericæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of ſeveral imbricated, ovate, acute leaves; the five innermoſt longeſt and equal. *Cor.*

of one petal, funnel-ſhaped; tube dilated upwards; limb in five equal, ovate, ſpreading ſegments. Nectary of five obovate blunt ſcales, cloſely ſurrounding the baſe of the germen. *Stam.* Filaments five, equal, very ſhort, inſerted into the ſummit of the tube of the corolla; anthers incumbent, roundiſh oblong, of two cells and two lobes, burſting longitudinally, deſtitute of any appendage. *Piſt.* Germen ſuperior, roundiſh, with five furrows; ſtyle cylindrical, rather ſhorter than the tube; ſtigma capitate. *Peric.* Capſule roundiſh, ſomewhat depreſſed, with five furrows, of five valves and five cells, the partitions from the centres of the valves. *Seeds* numerous, minute, angular, affixed to the central column.

Eſſ. Ch. Calyx imbricated. Corolla tubular. Stamens inſerted into its orifice. Scales five, at the baſe of the germen. Capſule ſuperior, of five cells and five valves, with partitions from their middle. Seeds numerous, chaffy.

The numerous ſpecies of this elegant genus, but few of which have, as yet, found their way into botanical books, are all natives of New Holland or New Zealand. They bear a general reſemblance to the vaſt Cape genus *Erica*, with which botaniſts have aſſociated them in natural order, not without ſome uncertainty. Willdenow enumerates but four ſpecies, of which the fineſt is E. *grandiflora*, Sm. Exot. Bot. v. 1. 75. t. 39. Curt. Mag. t. 982. (E. longiflora; Cavan. Ic. v. 4. 25. t. 344.) "Leaves heart-ſhaped, pungent, recurved, on footſtalks. Flowers pendulous." Native of dry ſandy places in New South Wales, flowering in October. Its chief beauty conſiſts in its copious long pendulous flowers, with a crimſon tube and white border.

To theſe are now added, E. *obtuſifolia*, Sm. Exot. Bot. v. 1. 77. t. 40. "Leaves elliptic-lanceolate, very obtuſe, and pointleſs, on ſhort footſtalks. Flowers drooping toward one ſide." Grows in a ſandy ſoil near Port Jackſon, New South Wales, bloſſoming in October. The flowers are cream-coloured, with a browniſh calyx.

E. *pulchella*, Cavan. Ic. t. 345. Curt Mag. t. 1170. Branches clothed with ruſty down. Leaves heart-ſhaped, recurved, pungent. Flowers axillary, crowded. Native of Port Jackſon. Flowers white, ſweet-ſcented.

E. *pungens*, Cavan. Ic. t. 346. Branches ſmooth. Leaves ovate, pungent. Flowers axillary, crowded. Tube cylindrical. Common about Port Jackſon. The flowers are copious, large, ſnow-white, and very fragrant, reſembling thoſe of a *Phlox* in ſize and figure. Cavanilles' plate, a truly miſerable repreſentation of this magnificent ſpecies, miſled Dr. Sims in Curt. Mag. to confound it with the laſt. We apprehend this laſt writer has committed a further error in taking the red-flowered ſpecies, repreſented in his t. 1199, for a variety of the *pungens*. They ſeem to us very diſtinct.

Forſter and Cavanilles confounded with the genus of *Epacris* that of *Styphelia*, whoſe fruit is a drupa, with five ſeeds.

EPACTHES, Επαχθης, in *Antiquity*, a feſtival celebrated in honour of Ceres, named Αχθεια, from αχθος, *i. e.* *grief*, in memory of her ſorrow, when ſhe had loſt her daughter Proſerpine.

EPACTS, in *Chronology*, the exceſſes of the ſolar month above the lunar ſynodical month; and of the ſolar year above the lunar year of twelve ſynodical months; or of ſeveral ſolar months above as many ſynodical months; and ſeveral ſolar years above as many dozen of ſynodical months.

The epacts, then, are either *annual* or *menſtrual*.

Epacts, *Menſtrual*, are the exceſſes of the civil or calendar month above the lunar month.

Suppoſe, *e. gr* it were new moon on the firſt day of January; ſince the lunar month is 29 days, $12^h\ 44'\ 3''$; and the month of January contains 31 days; the menſtrual epact is 1 day $11^h\ 15'\ 57''$.

Epacts, *Annual*, are the exceſſes of the ſolar year above the lunar.

Hence, as the Julian year is 365 days 6', and the Julian lunar year 354 days 8 48' 36', the annual epact will be 10 days $21^h\ 11'\ 22''$; that is, nearly 11 days. Conſequently, the epact of two years is 22 days; of three years, 33 days; or rather three, ſince 30 days make an emboliſmic, or intercalary month.

Thus the epact of four years is 14 days, and ſo of the reſt; and thus, every 19th year the epact becomes 0; conſequently, the 20th year the epact is 11 again; and ſo the cycle of epacts expires with the golden number or lunar cycle of 19 years, and begins with the ſame, as in the following table; which is formed by the conſtant additions of 11, caſting off 30; ſuppoſing the lunar month to conſiſt of 29 and 30 days, and the civil year of 365 days, with a biſſextile every fourth year. This natural order of the epacts is ſuch as was eſtabliſhed by the council of Nice, A.D. 325.

Gold. Numb.	Epacts.	Gold. Numb.	Epacts.	Gold. Numb.	Epacts.
1	XI	7	XVII	13	XXIII
2	XXII	8	XXVIII	14	IV
3	III	9	IX	15	XV
4	XIV	10	XX	16	XXVI
5	XXV	11	I	17	VII
6	VI	12	XII	18	XVIII
				19	XXIX

Again, as the new moons are the ſame, that is, as they fall on the ſame day every 19 years, ſo the difference between the lunar and ſolar years is the ſame every 19 years. And becauſe the ſaid difference is always to be added to the lunar year, in order to adjuſt or make it equal to the ſolar year; hence the ſaid difference reſpectively belonging to each year of the moon's cycle is called the "epact of the ſaid year," that is, the number to be added to the ſaid year, to make it equal to the ſolar year, the word being formed from the Greek επαγω, *induco, intercalo.*

Upon this mutual reſpect between the cycle of the moon and the cycle of the epacts, is founded this rule for finding the Julian epact, belonging to any of the moon's cycle. Multiply the year given of the moon's cycle into 11; and if the product be leſs than 30, it is the epact ſought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the epact. For inſtance, we would know the epact for the year 1712, which is the third year of the moon's cycle. Wherefore 3 is the epact for 1712, for 11 × 3 = 33, and 33 being divided by 30, there is left three of the dividend for the epact. But the difference of the Julian and Gregorian years being equal to the exceſs of the ſolar above the lunar year, or 11 days, it happens that the Gregorian epact for one year is the ſame with the Julian epact for the preceding year.

By the help of the epact may be found what day of any month in any year the new moon falls on, thus: to the number of the month, from March incluſively, add the epact of the year given; if the ſum be leſs than 30, ſubtract it out of 30; if greater, ſubtract it out of 60; and the remainder will be the day whereon the new moon will fall.

If the new moon be ſought for in the month of January or March, then nothing is to be added to the epact; if for February or April, then only one is to be added.

Thebes was taken by the Lacedæmonians, and Pelopidas with others attached to liberty and independence were expelled, but Epaminondas was ſuffered to remain, as one whoſe poverty and philoſophy would prevent him from taking any part in political concerns. When the exiles, about four years afterwards, regained the city, they were joined by Epaminondas, and the Thebans regained their liberty. Theſe two friends concurred in improving the military diſcipline of their fellow-citizens; and Epaminondas in particular took pains by his counſel and example, in promoting among them that frugality and contempt of pleaſure which lie at the foundation of all manly exertions. By ſuch conduct he gained the confidence of the Thebans, and being raiſed to a high rank in the army, he was deputed as a delegate to Sparta for the purpoſe of negociating a peace. On this occaſion, when the other deputies were overawed by Ageſilaus, who guided the operations of the Lacedæmonians, Epaminondas aſſerted the dignity of his character as the repreſentative of an independent ſtate, and inſiſted that the Thebans ſhould retain the ſame authority in Bœotia with that of the Spartans in Laconia. The Spartan king was incenſed, and war was immediately declared againſt the Thebans. The Lacedæmonians gave orders to their king Cleombrotus, to march into Bœotia at the head of an army conſiſting of 10,000 foot ſoldiers and 1000 horſe. The army of the Thebans was made up of only 6000 infantry and a ſmall body of cavalry; but Epaminondas commanded it, and under him was Pelopidas. The two armies met at Leuctra, a ſmall town of Bœotia, and on the 8th of July, B.C. 371, a battle was fought, which by the wiſdom and valour of Epaminondas terminated in the defeat of the Lacedæmonians, and the death of Cleombrotus. It afforded ſingular ſatisfaction to the victorious general that his father and mother had lived to witneſs the glory he now acquired. Two years after (B.C. 369) Epaminondas and Pelopidas were nominated Bæotarchs, or chiefs of the Bœotian league. The concurrence of circumſtances, mutual eſteem, friendſhip, and an uniformity of ſentiments and views, formed an indiſſoluble union between theſe two great men. With Pelopidas, the companion of his labours and his glory, Epaminondas entered Peloponneſus, ſpreading terror and deſolation through the ſtates in alliance with Lacedæmon, haſtening the defection of others, and breaking the yoke under which the Meſſenians had groaned for centuries. Seventy thouſand men of different nations marched under his orders with an equal confidence, and he led them on to Lacedæmon. Ageſilaus, appriſed of his approach, was anxious and alarmed; but ſuch was his reſiſtance, and the delay occaſioned by it, that Epaminondas thought it moſt prudent to retreat. After quitting the Spartan territories, he rebuilt the ancient city of Meſſene, and recalled its diſperſed inhabitants from the ſurrounding countries, in which they had long lived as aliens. It was the eſtabliſhed rule of the Bœotian league, that the chiefs ſhould hold their office only for a year, and then reſign to their ſucceſſors. Epaminondas and Pelopidas, however, retained their authority four months longer than the term preſcribed by law. For this they were accuſed, and judicially proſecuted. Pelopidas puſillanimouſly ſunk under the charge; but Epaminondas appeared before his judges with the ſame tranquillity as at the head of his army, and thus addreſſed them: "The law condemns me, I merit death, I only demand that this inſcription be engraven on my tomb: the Thebans have put Epaminondas to death, becauſe at Leuctra he forced them to attack and vanquiſh thoſe Lacedæmonians, whom they did not before dare to look in the face; becauſe his victory ſaved his country, and reſtored liberty to Greece; becauſe under his command the Thebans beſieged Lacedæmon, which deemed herſelf too fortunate to eſcape from ruin: and becauſe he rebuilt Meſſene, and ſurrounded it with ſtrong walls." The people preſent applauded this ſpeech, and the judges did not dare to condemn Epaminondas. In the next year Epaminondas marched again into Peloponneſus to aid the Arcadians againſt the Spartans; and having taken ſome towns and laid waſte the country, he marched to Corinth, which was ſucceſsfully defended againſt him. Upon his return, ſo uncertain is popular favour, he was deprived of his command, and reduced to the condition of a private citizen. After ſome time, an army being ſent to reſcue Pelopidas, who had been ſeized and impriſoned by the tyrant Alexander the Pheræan, Epaminondas ſerved in it as a private ſoldier, and in that humble rank preſerved the army from being utterly deſtroyed. His fellow-citizens reinſtated him in his command, and ſent him with freſh forces to recover his friend, whoſe life was ſuppoſed to be in imminent danger. Alexander was ſo intimidated that he acquieſced in a ceſſation of arms, on condition of releaſing Pelopidas and another deputy. Thebes had now arrived at ſuch a degree of importance among the Grecian ſtates, as to be preferred to Sparta and Athens by the Perſians, who, therefore, wiſhed to enter into a treaty with the Thebans. Pelopidas concluded the treaty, though the Theban allies demurred againſt it. Epaminondas was therefore deputed with an army to force the Achæans to continue the alliance; and in this buſineſs he ſucceeded, and a general peace ſoon followed. Epaminondas wiſhed to render his country as powerful by ſea as it was by land; and with this view he was deputed to negociate with the Rhodians, Chians, and other maritime people. The Thebans were ſtill purſuing their ambitious deſigns; and Epaminondas marched a powerful army into Peloponneſus: but, as a confederacy was formed againſt the Thebans, the troops of which aſſembled at Mantinea, Epaminondas, apprehending that Sparta would be left defenceleſs, made a ſudden march in order to ſurpriſe it. But Ageſilaus was ready to receive him. Informed by a deſerter of Epaminondas's march, he returned home with extraordinary celerity, and placed his ſoldiers in the moſt important ſtations. The Theban general ordered ſeveral attacks. He had penetrated to the forum, and made himſelf maſter of one part of the city, when Ageſilaus, then near 80 years of age, liſtening only to the dictates of deſpair, ruſhed into the midſt of danger, and ſeconded by the brave Archidamus his ſon, repulſed the enemy and compelled them to retire. Epaminondas was not moleſted in his retreat; but a victory was become neceſſary, that the failure of his enterpriſe might be forgotten. He therefore marched ſuddenly to Mantinea, expecting to find it unguarded; but here he was diſappointed. He determined, however, to riſk a battle for the purpoſe of retrieving his honour. The army of the Lacedæmonians and their allies conſiſted of more than 20,000 foot and near 2000 horſe; the army of the Theban league of 30,000 infantry and about 3000 cavalry. Never did Epaminondas diſplay greater abilities than on the preſent occaſion; ſo that the enemy, diſmayed at his appearance, betook themſelves to flight. But whilſt he was purſuing them with great ardour, they ſuddenly rallied, and poured upon him a ſhower of darts. At length one of them pierced his breaſt with a javelin, the point of which was left in his body. When he was carried off the ground to his tent, and had recovered his ſpeech, his firſt queſtion was, what was become of his ſhield? when it was brought him, he kiſſed it as the inſtrument of his labours and his glory. He then inquired concerning the event of the battle; and being informed

formed that the Thebans were victorious, he ſaid, "It is well; I have lived long enough;" or, as others report his declaration, "I die unconquered. Adviſe the Thebans to conclude a peace." The javelin being then extracted, he expired, B. C. 363. Epaminondas was never married; and he ſeems to have regarded celibacy as moſt favourable to his philoſophical purſuits in private life, and to his active ſervices in a public ſtation. On the plain where he fell, two monuments were raiſed to him, *viz.* a trophy and a tomb. Epaminondas is repreſented by Cicero as one of the greateſt men that any age or nation ever produced: and why, it is ſaid, ſhould we not grant this honourable diſtinction to the general who perfected the art of war, who eclipſed the glory of the moſt renowned commanders, and who was never vanquiſhed but by fortune; to the ſtateſman, who gave to Thebes a ſuperiority ſhe had never poſſeſſed, and which ſhe loſt immediately upon his death; to the negociator who, in the general aſſemblies and congreſſes of Greece, always maintained a ſuperiority over the other Grecian deputies, and found means to retain in the alliance of Thebes, his country, even the ſtates who were jealous of the growth of this new power; to the man who equalled in eloquence the greater part of the Athenian orators, was no leſs devoted to his country than Leonidas, and perhaps more juſt even than Ariſtides? Travels of Anacharſis, vol. ii. Corn. Nep. Vit. Epam. Plutarch Vit. Pelop. & Ageſil. Univ. Hiſt. vol. v. and vi.

EPANALEPSIS, Επαναληψις, called alſo *Epanadiploſis*, in *Rhetoric*, the repetition of the ſame word in the beginning of one ſentence, and at the end of another. Thus Virgil,

> "Ambo florentes ætatibus, Arcades ambo."

Such alſo is the expreſſion of Plautus (Amph. Act ii. Sc. 2. v. 21.): "Virtue contains all things: he wants no good thing who has virtue." The figure is the ſame, though the principle is leſs honeſt, which occaſions the advice given by the writer in Horace, (Epiſt. i. 1. 65.) "Get money, if you can, honeſtly; but, however, get money." This figure adds force to an expreſſion, when the principal thing deſigned to be conveyed is thus repeated, ſo as to leave its impreſſion laſt upon the mind. And the beauty is heightened, when the ſentence has an agreeable turn ariſing from two oppoſite parts; as in Cicero's compliment to Cæſar, (Pro Marcell. c. 6.): "We have ſeen your victory terminated by the war: your drawn ſword in the city we have not ſeen." Hermogenes (Sturm. de Univerſ. Eloc. p. 410.) calls this a *circle*, becauſe the ſentence returns again to the ſame word. See Anadiplosis.

EPANAPHORA, Επαναφορα, the ſame with anaphora.

EPANA'STASIS, (from επι, and ανιστημι, *to excite*,) in *Surgery*, a tumour, or tubercle.

EPANASTROPHE, Επαναστροφη, in *Rhetoric*, the ſame with what is otherwiſe called anadiploſis.

EPANCYLO'TUS, (from επι, and αγκυλος, *crooked*), in *Surgery*, a bandage deſcribed by Oribaſius.

EPANODOS, Επανοδος, in *Rhetoric*, an inverſion of a ſentence, or a repetition of the ſame words in an inverted order; thus:

"Nox brevis nimis, ah! nimis brevis nox." Voſſ. Rhet. lib. v. p. 298.

This figure comprehends both *anadiploſis* and *epanalepſis*; for it both begins and ends with the ſame word, and the ſame word is likewiſe repeated in the middle. This turn of expreſſion has a beauty in it, and ſhews a readineſs of thought. Minutius Felix has given an example of it, when he is expoſing the folly of the Egyptian ſuperſtition. "Iſis," ſays he, "with Cynocephalus, and her prieſts, laments, bemoans, and ſeeks her loſt ſon; her attendants beat their breaſts, and imitate the grief of the unhappy mother: in a little time the ſon is found, upon which they all rejoice. Nor do they ceaſe every year to loſe what they find, or to find what they loſe. And is it not ridiculous to lament what you worſhip, or to worſhip what you lament?" This figure ſerves likewiſe to illuſtrate and enforce the ſenſe by ſetting it in two oppoſite views. Such is the expreſſion of the prophet (Iſ. v. 10.) "Wo unto them, who call good evil, and evil good: who put darkneſs for light, and light for darkneſs."

EPANORTHOSIS, or Correction, in *Rhetoric*, a figure by which the orator revokes and corrects ſomething before alleged, as too weak, and adds ſomething ſtronger and more conformable to the paſſion by which he is agitated.

The word is formed of ορθος, *right*, *ſtraight*; whence ορθοω, *I ſtraighten*; ανορθοω, επανορθοω, *I redreſs*, *ſtraighten*, *correct*, and επανορθωσις, *correction*. Accordingly the Latins call it *correctio* and *emendatio*.

This figure is uſed in different ways. Sometimes one or more words are recalled by the ſpeaker, and others ſubſtituted in their room. At other times, without recalling what has been ſaid, ſomething elſe is introduced as more ſuitable, inſtances of both kinds follow.

Such, *e. gr.* is that of Cicero for Cœlius: "O ſtultitia! ſtultitiamne dicam, an impudentiam ſingularem? Oh folly! folly did I call it, or rather intolerable impudence?" And in the firſt Catilinarian: "Quanquam quid loquor? Te ut ulla res frangat? Tu ut unquam te corrigas? Tu ut ullam fugam meditare? Tu ut ullum exilium cogites? Utinam tibi iſtam mentem dii immortales donarent." Thus alſo Terence, in the Heautontimo-rumenos, introduces his old man Menedemus, ſaying,

> "Filium unicum adoleſcentulum
> Habeo. Ah! quid dixi habere me? imo habui, Chreme.
> Nunc habeam necne, incertum eſt." "I have an only ſon, Chremes. Alas! did I ſay, that I have? I had indeed; but it is now uncertain, whether I have or not."

Cicero, in his defence of Milo, ſpeaking to the judges concerning Clodius ſays; "Are you only ignorant, what laws, if they may be called laws, and not rather torches and plagues of the ſtate, he was about to impoſe and force upon us?" Again, in his defence of Plancius he ſays: "What greater blow could thoſe judges, if they are to be called judges, and not parricides of their country, have given to the ſtate, than when they baniſhed him, who, when prætor, freed the republic from a neighbouring war, and when conſul from a civil one?" Here he is ſpeaking of Opimius: but in commending the moderation of Lucius Mummius who did not enrich himſelf, but his country, by demoliſhing the wealthy city of Corinth, he thus recalls his whole expreſſion, and by giving it a new turn, heightens the compliment he deſigned him. "He choſe rather," ſays he, "to adorn Italy, than his own houſe, though by adorning Italy his houſe ſeems to have received the greateſt ornament." De Off. l. ii. c. 22. Sometimes the correction is made by ſubſtituting ſomething contrary to what had been ſaid before: as in the following paſſage of Cicero (Philipp. iii. c. 2.): "Cæſar" (meaning Auguſtus), "though but a youth, by an incredible and ſurpriſing reſolution and courage, when Antony was moſt enraged, and we dreaded his cruel and pernicious return from Brundiſium, at a time when we neither aſked, nor expected, nor deſired it (becauſe it was thought impoſſible) raiſed a very powerful army of invincible veterans, to effect which he threw away his whole eſtate. Although I have uſed an improper word; for he did not throw it away, but employed it for the ſafety of the government." At other times, as we have before obſerved, the correction is made by adding a more ſuitable word, without any repetition of the former. Thus Cicero, after he has inveighed againſt the crimes of Verres (lib. ii. c. 29.) breaks out into this pathetic exclamation: "O the clemency, or rather wonderful and ſingular patience of the Roman people?" The word *clemency* not being, in his apprehenſion, ſtrong enough, he adds *patience*, as better anſwering his purpoſe. The ſudden and unexpected turn of this figure gives a ſurpriſe to the mind, and by that means renders it the more pathetic.

EPANTHE'SMA, or Epanthísma, (from επι, and ανθος, *a flower*), in *Surgery*, an effloreſcence; exanthema.

EPAPHÆ'RESIS, (from επι, importing *a repetition*, and αφαιρησις, *a removal*). In Galen it is employed in the ſenſe of a repeated evacuation by bleeding.

EPARCHA, in the *Muſic of the Ancients.* Pollux, (Onomaſt. lib. iv. cap. 9.) tells us, that the eparcha was one of the ſtrains of the Citharian mode, according to the diviſion of Terpander. It was probably the prelude, for that is the ſignification of the word eparcha.

EPARCHUS, Επαρχος, an officer under the Greek emperors of Conſtantinople, who had the command of the guards, or government of a province.

EPARER, in the *Manege*, is uſed to ſignify the flinging of a horſe, or his yerking or ſtriking out with his hind legs. In caprioles, a horſe muſt yerk out behind with all his force; but in ballottades he ſtrikes but half out; and in croupades he does not ſtrike out his hind legs at all. All horſes that yerk are reckoned rude. See Yerking.

EPA'RGEMOS, (from επι, and αργεμον, ſignifying a white ulceration, or opacity of the eye), in *Surgery*, an epithet applied to a perſon affected with the diſorder called argemon.

EPARITA, in the *Materia Medica*, a name given by Paracelſus to a ſort of fine earth, of a liver colour, ſeemingly the ſame with the Tokay bole.

EPA'RMA, or Epa'rsis, (from επι, and αιρω, *to elevate*,) in *Surgery*, a tumour of any ſort. The term, however, is uſually confined to a ſwelling of the parotid gland.

EPARRES, in *Geography*, a ſmall town of France, in the department of the Iſére, near Vienne.

EPAULE, or Espaule, in *Fortification*, the ſhoulder of the baſtion, or the angle made by the face and flank, otherwiſe called the angle of the epaule. See Bastion and Angle.

The word is pure French, and literally ſignifies *ſhoulder*.

Epaule *en dedans*, in the *Manege*, a leſſon of late invention, which, rendered into Engliſh, denotes that attitude in which, as the horſe goes forward, he is ſo bent through his whole frame, that if he goes to the right hand, he muſt croſs the right fore-leg over the left, and ſo *vice verſâ*; or, in the language of the Manege, his inner ſhoulder, or leg, over the outward. The old maſters worked their horſes upon circles, when they intended to ſupple the ſhoulders and haunches; but to this mode of working upon circles, it has lately been objected that it conſtrains the fore-part too much, and throws the horſe upon his ſhoulders. To remedy this evil, M. de la Guerriniere, an accompliſhed horſeman at Paris, invented the leſſon called "epaule en dedans," and eſtabliſhed it in his Manege. This new method, however, differs very little from the old practice, to which it owes its origin, and from which it is extracted and formed. The only objection againſt the circle is, that the horſe, when worked circularly, has his haunches too much at liberty, by which means the weight of his body is thrown upon his ſhoulders, which are thereby impeded in their motion; and the animal compelled to work in a manner directly oppoſite to what he ſhould do. The blame, however, inſtead of being laid on the circle, ſhould have been aſcribed ſolely to the falſe and ſenſeleſs manner in which horſes were formerly worked in it; when heavy large bitts and caveſons were uſed, with which the heads of horſes were loaded, and brought down to a level with their knees, ſo that they carried them, like rams, when they fight, and batter one another with their foreheads. Had theſe old practitioners known the advantage, and, indeed, the neceſſity of raiſing the head, in order to preſs and bend the haunches, and of doing this by means of a ſnaffle with double reins, one being tied over the withers, on the oppoſite ſide to which the horſe is to turn, the head would at once have been raiſed, the outward ſhoulder brought in, and the horſe bent from noſe to tail; but this diſcovery was reſerved for ſir Sidney Medows, who has made many important improvements in the art of horſemanſhip. Berenger's Hiſt. &c. of Horſemanſhip. vol. ii.

EPAULEMENT. In treating of the enfilade, we had occaſion to notice this part of the defences of batteries expoſed to a flanking-fire. The deſignation is derived from the French word *epaule*, meaning "a ſhoulder," to which the epaulement bears a ſtrong reſemblance. Wherever a work, whether on the defences, or in the approaches of the beſiegers, is ſubject to be enfiladed, and eſpecially where that enfilade is *direct*, it becomes indiſpenſibly neceſſary to raiſe an epaulement, for the purpoſe of warding off the ſhot. The thickneſs of ſuch a buttreſs muſt always be proportioned to its height, which again muſt be carried up ſo far as may render the fartheſt gun, upon the battery to be ſecured, ſufficiently ſafe from the ordinary *lobs* of ſhot fired en ricoçhet, as well as ſuch as may enfilade by deſcent. A general rule may be eaſily formed; namely, that the epaulement ſhould be full as thick as the parapet, be about ten feet, if practicable, beyond the prolonged line of the inner revetement of the terre-pleine, and be raiſed high enough to make an angle of ten degrees from the horizontal; the farther end of the battery being the angular point formed by the meeting of the terre-pleine, with a line drawn from the creſt of the epaulement. If this proportion be properly attended to, it will be almoſt impoſſible to enfilade the defences with effect; becauſe few ricoçhet ſhots, fired at an angle of ten degrees, will riſe more than eight at their ſecond flight. This mode gives a kind of ſtandard, which proportions the height of the buttreſs to the length of the battery it is to protect.

Where there is ſpace for ſuch a work, it is often found highly advantageous to raiſe cavaliers at the extremities of the baſtions, &c. which by their height ſerve as epaulements; but, as ſuch defences, when they fall into the hands of the beſiegers, not only afford a lodgment, but command the adjacent works, it is abſolutely neceſſary they ſhould be ruined; ſo that they may be completely annihilated whenever they are wreſted from the defenders. It being a general rule, that the creſt of the parapet ſhould be full ſeven feet in height, very little elevation thereof will make a competent epaulement for a battery of ſmall force, and eſpecially where the cannon are placed as cloſe up to the flank as circumſtances may admit. This cannot be done ſo eaſily in ſaliant angles which are acute, that is, under 90°; but, in the flanked angles of baſtions, &c. is generally very practicable. In the batteries and places of arms conſtructed by the beſiegers, the epaulements may be made within ten feet of the outer cannon, and may be run up to any height, provided they do not obſtruct the operations of other batteries; which, indeed, can be the caſe only in very peculiar ſituations. The beſt engineers recommend, that the epaulement ſhould be merely temporary, except at the orillons on the extremities of the flanks of baſtions, where they are always requiſite to prevent ſuch ſhots as may paſs over the proximate baſtion, when its angle or face may be battered, from enfilading the battery or the face of that baſtion next to ſuch orillon. When made on emergency, ſand bags are found to anſwer admirably in the conſtruction of epaulements; but when intended to be permanent, the buttreſſes ſhould be made of the firmeſt ſoil, well compacted, and properly gazoned (*i. e.* turfed.) As we have remarked, while ſpeaking of enfilades, no maſonry ſhould be expoſed in the conſtruction of epaulements any more than in traverſes and parapets; on account of the incalculable miſchief done by the numerous ſplinters which are knocked off by ſuch ſhots as ſtrike thereon.

EPAULETTE, is a diſtinguiſhing ornament, worn upon the ſhoulders of commiſſioned and of non-commiſſioned officers of ſome deſcriptions. The epaulette is always made to correſpond in colour with the bindings and lace of the uniform: therefore where yellow binding is in uſe, gold embroidery, &c. are employed, and where white binding is adopted, ſilver embroidery only is ſuitable. The military ſervice is by no means uniform in this ornament, ſome being epaulettes of one, ſome of another pattern; according to the fancies of the commandants reſpectively. The general rule is, that all general and field officers, as well as all ſuperior ſtaff officers, wear two epaulettes, the reſt of the officers in a corps wearing but one. Though, as above ſtated, variety obtains, yet the generality conſiſt of a rich ſtrap, of gold or ſilver lace, cuſhioned below, to give it a ſquare appearance upon the ſhoulder, and ornamented at its lower extremity with rich bullion, and fringe of a correſponding deſcription; the upper end ordinarily faſtens under, or on the cape, to a button; ſome being moveable, for the purpoſe of admitting a belt to paſs underneath. The flank companies, *i. e.* the grenadiers and light infantry, generally wear wings, not altogether unlike creſcents as they fit on the ſhoulder; of theſe the edges are ornamented with ſhorter bullions and fringe than are uſed in epaulettes. Some wings have ſhoulder-ſtraps, others have none; and ſome are ribbed, or ſtriped with narrow lace; but the generality are plain. In the navy, only large gold epaulettes are worn; all captains having two, and all under that rank but one. Formerly ſhoulder-knots, preciſely reſembling thoſe in uſe among ſervants, were worn by many corps, eſpecially the artillery. Theſe originated in the uſe of chains, ſuſpended from the collar down the arms, for the purpoſe of warding off the cuts of ſabres; but they ultimately became merely decorative, and were from that period made of ſilver cords, plaited, looped, and tagged, which hung down generally in front of the ſhoulder. For the ſame purpoſe of defence, the cavalry have in ſome inſtances adopted a laminated epaulette, conſiſting of metal plates of various patterns, but commonly circular or oval, overlapping each other a little, ſo as to allow due play to the limb, yet forming no ſlight reſiſtance againſt a ſabre. It cannot be expected, that the ſhoulder ſhould altogether eſcape injury, even though the edge of the weapon ſhould be averted; ſince the ordinary force of an attempt to cut down the ſhoulder muſt prove extremely painful, and generally benumb the part for a while; or eventually cauſe a bruiſe of ſome conſequence.

It is evident, from what we have detailed, that the epaulette may be conſidered as the type of a certain portion of armour, in uſe not many years ago; but which has become leſs neceſſary ſince diſcipline has empowered infantry to reſiſt cavalry; and as the former laid aſide their broad-ſwords in deference to the adoption, and to the ſuperiority of the muſquet and bayonet.

Though, in ſome parts of the Britiſh ſervice, the corporals ſtill wear ſhort ſhoulder-knots, and the ſerjeants retain their epaulettes, both being of cotton, worſted, or ſilk, the generality of them now wear the diſtinguiſhing marks of their reſpective ranks, in the form of fleches, or angular lacings on their ſleeves. Some variation exiſts in this particular, according to the nature of their employ; but, in general, one, two, and three fleches are the ordinary indications of rank. Thus, where an order of merit is eſtabliſhed among the privates, ſuch as appertain thereto wear one fleche, the corporals having two, and the ſerjeants three. This mode does not, however, ſeem to carry ſo much notoriety with it as the epaulette, which can be ſeen both from before and from behind the individual wearing it; whereas the fleche can be diſtinguiſhed but in one particular point of view.

EPEE, in *Geography*, a port of Africa, in the country of Benin.

EPEMBOLE, Επεμϐολη, in *Rhetoric*, the ſame with parembole.

EPENCRANIS, a name by which ſome of the old authors, particularly Eraſiſtratus, have called the cerebellum.

EPENDYTES, Επενδυτες, among the Greeks, a garment worn under the pallium, and above the interula or inner coat, called, in Greek, ὑποδυτης.

EPENTHESIS, formed of επι, εν, and τιθημι, *q. d.* επεντιθημι, *inſero*, *immitto*, in *Grammar*, the addition, or inſertion of a letter or ſyllable, in the middle of a word; as *relligio* for *religio*, *Mavors* for *Mars*, *alituum* for *alitum*. Virg. Æn. lib. vii. ver. 27.

In the Hebrew language, there are ſome letters which are called *epenthetic*, and they occur without any apparent neceſſity in the middle of words; ſuch are אוין. Maſclef's Heb. Gram. v. i. p. 191.

EPERIES, in *Geography*, a town of Hungary, celebrated for its mines of ſalt; 20 miles N. of Caſchau.

EPERLANUS, in *Ichthyology*, a name ſometimes given, on account of its pearl colour, to the ſmelt. See Salmo *Eperlanus*.

EPERLEQUE, in *Geography*, a town of France, in the department of the Straits of Calais; 2 leagues N.W. of St. Omer.

EPERNAY, or Espernay, an ancient and handſome town of France, in the department of the Marne, chief place of the diſtrict of the ſame name, with a population of 4430 individuals. It is pleaſantly ſituated on the river Marne, 21 miles N.W. of Châlons ſur Marne, 18 miles S. of Rheims, and 88 miles E. by N. of Paris. N. lat. 49° 2'. The canton has a territorial extent of 110 kiliometres, 11 communes, and 13,958 inhabitants.

As chief place of a diſtrict, Epernay has a ſub-prefect, a ranger, a court of juſtice, and a regiſter office. There are ſeveral manufactures of woollen ſtuffs, hoſiery, cutlery, leather, and writing-paper; but the moſt remarkable is that of a ſort of glazed earthen-ware, which ſtands the hotteſt fire.

The diſtrict of Epernay has 10 cantons, 215 communes, and 87,413 inhabitants, on a territorial extent of 2592½ kiliometres. Its ſoil is uncommonly fertile, and produces corn, but eſpecially that excellent red and white champaign of the very firſt quality, which is ſo much ſought for all over the world. Epernay is the centre of the beſt champaign wines; its own vineyards and thoſe of Ay produce the beſt; and the town has a great trade not only with theſe, but alſo with the famous wines of the hills of Hautvilliers, Pierry, and Cumieres, which are not far diſtant.

EPERNON, a town of France, in the department of the Eure and Loire; 4 leagues N.E. of Chartres.

EPERON, in *Natural Hiſtory*, the ſpur-ſhell, ſo called from its reſembling, in ſome degree, the rowel of a ſpur. It is a ſpecies of ſnail, of the round-mouthed kind, or claſs of the cochleæ lunares; all its volutæ are ſurrounded with double rows of prickles. See Lunaris *Cochlea*.

EPERONNIER, in *Ornithology*. See Pavo *Bicalcaratus*.

EPERUA, in *Botany*. See Dimorpha.

EPERVIER. See Falco.

EPERVIERS, in *Natural Hiſtory*, a name given by the French authors to a claſs of butterflies, which make the ſixth in Reaumur's method. They have a way of poizing themſelves on the wing in the manner of kites, and other birds of prey; and always live upon the wing, never ſettling themſelves upon the flowers they feed upon, but keep flying with a humming noiſe like a humble bee, while they thruſt in their trunk and ſuck the juices of the flower.

EPETIUM, in *Ancient Geography*, a town of Illyria, on the coaſt of Dalmatia, between Salone and Pegentium, near the mouth of a river, now called Xarnouvriza. The town which has ſucceeded to Epetium is named *Strobez*.

EPHA, a dry meaſure in uſe among the Hebrews.

The epha was the moſt common meaſure they uſed, and that whereby the reſt were regulated. It is commonly ſuppoſed that the epha, reduced to the Roman modius, contained four modii and a half. Now the Roman modius of grain or flour contained twenty libræ or pounds, conſequently the epha weighed ninety pounds. Dr. Arbuthnot reduces the epha to three pecks three pints, Engliſh meaſure. See Measure.

EPHALGIA, in *Ancient Geography*, now *Elpiſura*, a town of Aſia, in Meſopotamia, upon the banks of the Euphrates, W.N.W. of Circeſium.

EPHEBÆUM, Εφηβειον, in *Antiquity*, the place where the ephebi or youth exerciſed; or, as ſome ſay, where thoſe who deſigned to exerciſe met, and agreed what kind of exerciſe they ſhould contend in, and what ſhould be the victor's reward.

EPHEBI, Εφηβοι, among the Athenians, a deſignation given to their young men when they arrived at eighteen years of age, at which time they had their names entered in a public regiſter. Pott. Archæol. Grec. lib. 1. cap. 9. tom. i. p. 48.

EPHEDRA, in *Botany*, (εφεδρα is an ancient name for a climbing or paraſitical plant, and expreſſes a ſitting upon any thing; hence it ſeems to allude to the ſquat or decumbent and crowded habit of this ſhrub.) Sea ſide Grape. Linn. Gen. 532. Schreb. 707. Willd. Sp. Pl. v. 4. 858. Mart. Mill. Dict. v. 2. Juſſ. 411. Claſs and order, *Dioecia Monadelphia*. Nat. Ord. *Coniferæ*.

Gen. Ch. Male, *Cal.* the ſcales of a catkin, few, ſingle-flowered, roundiſh, concave, each the length of the perianth, which is of one leaf, cloven half way down, roundiſh, inflated, compreſſed, ſmall and blunt. *Cor.* none. *Stam.* Filaments ſeven, united into an awl-ſhaped column, cloven at the top, and longer than the calyx; anthers roundiſh, turned outwards, four of them below the reſt. Female, *Cal.* Perianth five-fold, one placed upon another ſo that their ſegments are alternate, forming an ovate figure; each is nearly ovate, of one leaf, cloven, the outer or lower ones ſmalleſt. *Cor.* none. *Piſt.* Germens two, ovate, the ſize of the innermoſt perianth on which they ſtand; ſtyles two, ſimple, thread-ſhaped, ſhort; ſtigmas ſimple. *Peric.* none; except the perianths, all become ſucculent and thickened, conſtituting a divided berry. *Seeds* two, ovate, acute, convex on one ſide and flat on the other, compreſſed by the perianth which incloſes them on every ſide.

Eſſ. Ch. Male, Calyx the ſcale of a catkin, in two ſegments. Corolla none. Stamens ſeven. Anthers four inferior; three ſuperior. Female, Calyx cloven, five-fold. Corolla none. Piſtils two. Seeds two, incloſed in the pulpy calyx.

The ſpecies known are but two.

1. E. *diſtachya*. Linn. Sp. Pl. 1472. Duhamel Arb. t. 92. (Uva marina; Ger. emac. 1116. f. 1, and 1117. f. 2.) "Flower-ſtalks oppoſite. Catkins in pairs." Native of various parts of the ſouth of Europe, in a ſandy ſoil about the ſhores of the ſea or of lakes, flowering in June and July. It bears our climate, eſpecially if led upright againſt a wall. A fine buſh of this kind may be ſeen in the Oxford garden, ten or twelve feet high. It is a buſhy, ſmooth, leafleſs ſhrub, always green, with the habit of an *Equiſetum*. The *catkins* are yellowiſh. *Berries* ſcarlet, ſweetiſh, viſcid, eatable but not agreeable.

2. E. *monoſtachya*. Linn. Sp. Pl. 1472. (E. polygonoides; Pall. Roſſ. v. 1. t. 83.) "Flower-ſtalks ſeveral. Catkins ſolitary." Native of Siberia. Linnæus ſuſpected this to be only a variety of the laſt, and Pallas confirms his opinion.

EPHELÆUM, in *Anatomy*, is the place from the hypogaſtrum, or lower part of the abdomen, to the ſecret parts.

EPHE'LCIS, from επι, and ἑλκος, *an ulcer*, in *Surgery*, a ſcab, or cruſt, upon a ſore.—Alſo, a ſmall portion of blood, voided by coughing.

EPHELIS, from επι and ἡλιος, *ſun*, a name uſed by the ancient writers on *Medicine*, for a diſorder of the face, brought on by the ſun and drying winds, and of the nature of what we call ſun-burning. It was a certain roughneſs, hardneſs, and bad colour of the ſkin.

The ephelis, or ſun-burning, is removed by an application of reſin, to which a third part of foſſile ſalt, and a little honey are added; but all theſe diſorders, as alſo the unnatural colour of cicatrices, are remedied by the following preparation, aſcribed to Trypho the Elder:

Take equal quantities of myrobolans, crocomagna, cimolian earth of a blueiſh colour, bitter almonds, the meals of barley and bitter vetch, dyer's weed (ſtruthium album); all theſe are to be triturated together, and made up with the moſt ſharp honey. With this preparation the parts affected are to be anointed at night; and the medicine carefully to be waſhed off the next morning. James Med. Dict. See Freckles.

EPHEMERA, from ἐπὶ and ἡμερα, *a day*, in *Medicine*, the name given by the Greek writers to the mildeſt form of fever, which runs through its courſe within the period of one day. By the Romans the ſame fever was termed *diaria*, from *dies*, a day.

A fever which terminates in the courſe of twelve, eighteen, or twenty-four hours, is not a common occurrence in this climate; unleſs the ſlight diſturbance of the ſyſtem, which fatigue, repletion, a ſleepleſs night, &c. induce, is to be called an ephemeral fever: and ſuch, indeed, appears to be the diſorder to which the term ephemera has been applied by writers in general, and which conſtitutes the ephemera ſimplex, or legitima, in their nomenclature. When the febrile condition is more ſevere, and therefore of longer duration, extending to the third or fourth day, by a ſoleciſm in language, it has been denominated ephemera extenſa, or ephemera plurium dierum. Any ſlight fever, of three or four days duration, is occaſionally called an ephemera at preſent; the ſlight derangement of the habit, from the operation of the cauſes juſt mentioned, being ſcarcely deemed a diſeaſe worthy of a diſtinct appellation.

The ephemera ſimplex is a ſlight febrile paroxyſm, marked by languor, loſs of appetite, thirſt, headache, and ſlight pains in the limbs, with ſome heat of ſkin terminating in a gentle perſpiration, and with dryneſs of the tongue and fauces. Theſe ſymptoms, from their mildneſs, imply a very ſlight derangement of any of the functions of the body: they originate from ſome evident cauſe of diſorder in what have been abſurdly termed the non-naturals, and ceaſe ſpontaneouſly when the influence of theſe cauſes no longer operates. The mildneſs of the ſymptoms, and the nature of the evident cauſes, are mentioned as the principal means of diſcriminating the ephemera from the various forms of continued fever at their commencement. Among the cauſes of the ephemera are enumerated the various paſſions of the mind, when ſtrongly excited, as grief, anger, joy, or care and anxiety, likewiſe loſs of ſleep, exceſſive heat of the weather, fatigue from labour or exerciſe, a fit of intoxication or of repletion, ſudden expoſure to cold, faſting, too great evacuations, &c. It is admitted, indeed, that many of theſe cauſes occaſionally give riſe to continued fevers of long duration; but, in theſe caſes, the attack is preceded by cold chills and ſhiverings, by languor and laſſitude, loathing of food, &c. and is accompanied by more ſevere diſorders of the functions, as by violent headache, pains in the back and limbs, nauſea or vomiting, with great anxiety and reſtleſſneſs. The preſence or abſence of theſe ſymptoms, in the commencement, will enable us to anticipate the future progreſs of the diſeaſe, whether it will be a mere ephemera or a more ſerious continued fever.

Beſides the ſimple ephemera, ariſing from the cauſes already enumerated, which Sauvages has included under the four heads of ephemera plethorica, ephemera nauſeativa, ephemera à frigore, and ephemera à calore, thoſe ſlight febrile derangements, connected with bruiſes, diſlocations, parturition, congeſtion of milk in the breaſts, dyſmenorrhœa, &c. have been alſo deſignated by the term ephemera; which, in this caſe, is a ſecondary or ſymptomatic ephemera. Avicenna, among the ancients, and Foreſtus, among the modern phyſicians, have made a ſtill more extenſive diviſion of ephemera; namely, into as many ſpecies as there are evident cauſes which induce it. Hence they uſeleſsly diſtinguiſh ephemera from grief, from joy, from hope, from fear, from thirſt, from faſting, &c.

The original ſignification of the term implied a completion of all the ſtages of a fever, *viz.* the beginning, increaſe, acmè, and decline, (in the language of the ancients,) within the compaſs of a natural day. By this definition, Van Swieten obſerves, the moſt acute fevers, which often kill a patient in twenty-four hours, are excluded from the term; ſince they do not arrive at their declenſion in that ſpace of time, although they end in death. Yet Caius has deſcribed that fatal epidemic, the *ſweating ſickneſs*, or *ſudor Anglicus*, under the term of ephemera; becauſe, on the one hand, it often terminated in the ſpace of twenty-four hours, by deſtroying the patient; and, on the other, by a ſweating, continued for the ſame ſpace of time, the patients were often cured. But in this caſe, though immediate danger was removed, yet great debility and other injuries to the functions ſtill remained, for ſome time afterwards; ſo that the diſeaſe belonged to the claſs of continued malignant fevers. This diſeaſe, under the appellation of ephemera ſudatoria, conſtitutes the ſeventh ſpecies of Sauvages. It has been alſo denominated ephemera Britannica, ephemera maligna, ephemera Anglica peſtilens, &c. See SWEATING *Sickneſs*.

With reſpect to the *cure* of the ephemeral fever, little remains to be ſaid. The term implies that its natural termination will occur within the period of a day, if left to itſelf: we here ſpeak of the ſimple ephemera, ariſing from a ſlight temporary cauſe. Abſtinence alone, or the moſt light and ſlender diet, with diluent drinks, is all that is required. The bowels may be opened by gentle aperients, as neutral ſalts, infuſion of ſenna, &c.: and this ought not to be omitted, where the diſeaſe has ariſen from over-repletion, or intoxication; in which caſe, it will contribute directly to remove the exciting cauſe of the diſorder. Thin drinks, ſuch as ſpring-water, or barley-water, acidulated or not with the juice of lemons, tea, or the infuſions of other grateful herbs, may be uſed, and animal food abſtained from.

The ſame treatment will be uſeful in the ſecondary or ſymptomatic forms of ephemera; in which caſes, however, the cure or alleviation of the original diſorder muſt be the firſt ſtep towards removing the ephemera. See Galen Method. Medend. lib. viii. De Febribus, lib. i. &c. Van Swieten, Comment. App. 728. Burſerius Inſtit. Med. tom. i. ſect. 198. Sauvages Noſ. Meth. claſs ii. genus 1.

EPHEMERA, in *Entomology*, a genus of the neuroptera order. This genus has the mouth deſtitute of mandibles; feelers four, very ſhort, and filiform; jaws ſhort, membranaceous, cylindrical, and connected to the lip; antennæ ſhort and ſubulate; ſtemmata too large above the eyes; wings erect; the lower ſmaller; tail terminating in briſtles.

The ephemeræ are proverbially a race of beings deſtined to enjoy the functions of life for a much ſhorter period than any other animals. This is a popular opinion, and, in a partial view of their hiſtory, not altogether incorrect; but it muſt be underſtood only of the laſt or winged ſtate, after attaining which they exiſt but for a few hours. The duration of this period varies in different ſpecies. It is devoted ſolely to the pleaſures of fulfilling the ordinary purpoſe of nature, the propagation of their kind; in the accompliſhment of which the ephemeræ may be obſerved in myriads, during the ſummer ſeaſon, ſporting on the wing, juſt above the ſurface of the water. In the larva and pupa ſtates the ephemeræ live one or two years; and ſome ſpecies, it is believed, live even three years from the time of hatching from the egg ſtate, before they arrive at the perfect form. The larvæ are found in the water, wherein they conſtantly reſide, and are the favourite food of fiſhes. They are active, furniſhed with ſix legs, a tail, ſix lateral fins or gills, and prey on ſmaller inſects. The pupæ, like the larvæ, are carnivorous, and reſemble the former ſtate, except in having the rudiments of the wings apparent. The ephemeræ are ſo abundant in ſome countries, that they are uſed for the purpoſe of manure, the ſpecies vulgata eſpecially. This is the common practice with the huſbandmen in Carniola. They are alſo very numerous on ſome parts of the Rhine, the Maes, and Iſel. The ſeaſon of their appearance in ſuch multitudes continues, however, only for about three days annually. The ephemeræ are arranged in two ſections, according to the number of briſtles at the extremity of the tail.

Species.

* *Tail with three hairs or briſtles.*

VULGATA. Wings reticulated, and ſpotted with brown; body yellowiſh, ſpotted with black. Scop. Donov. Brit. Inſ., &c.

Inhabits watery places throughout Europe.

Lutea. Wings tranſparent, reticulated; body yellow. Fabr.

Native of Europe, and is found in Britain.

Marginata. Wings white; exterior margin fuſcous; body black. Fabr.

Similar to E. vulgata, but ſmaller.

Vespertina. Wings black; poſterior ones white. Linn.

Native of Sweden, and other parts of Europe.

Halterata. Wings two, white; abdomen whitiſh, with fuſcous tail. Fabr. *Phryganea cauda triſeta*, &c. Degeer.

Inhabits ſtagnant waters in the north of Europe.

Inanis. Wings hyaline; body black; ſegments of the abdomen from the fourth to the ſeventh pellucid. Linn.

Native of Europe.

Maroccana. Wings white, immaculate; body yellowiſh. Fabr.

Found in Morocco.

Brevicauda. Wings two, cinereous, with a black rib; abdomen pale; tail brown. Fabr.

A ſmall ſpecies, found in the vicinity of Paris.

*** Tail with two hairs or briſtles.*

Bioculata. Wings white reticulated; head with two yellow tubercles; tail yellow. Fabr. Geoff., &c.

Native of European waters.

Renosa. Wings white reticulated; body brown. Fabr.

Inhabits Denmark.

Nigra. Body black; wings blackiſh; poſterior pair very ſmall. Linn.

Deſcribed by Linnæus as a native of Sweden; alſo inhabits other parts of Europe.

Culiciformis. Wings white; body brown. Linn.

Found in Greece by Pada; alſo in Sweden by Linnæus, and in France by Geoffroy.

Horaria. Wings white; thicker-margin blackiſh. Linn. *Ephemera minima*, Swammerdam.

Very abundant in Europe.

Striata. Wings hyaline, ſtriated; thorax fuſcous; abdomen white. Fabr. *Ephemera mutica*, Linn. Fn. Suec.

An European ſpecies.

Diptera. Wings two; coſtal margin brown, with cinereous ſpots. Linn.

The abdomen in this inſect is marked with red lines. The ſpecies inhabits Sweden.

Fuscata. Wings hyaline; abdomen brown, with the baſe whitiſh; legs pale. Fabr.

Albipennis. Wings white, immaculate; abdomen pale at the baſe; tail blackiſh. Fabr.

This and the preceding inhabit France, and other parts of Europe.

Notata. Yellow; wings white; abdominal ſegments with a fuſcous ſpot each ſide. Linn.

Ephemera notata and the three following are inhabitants of watery places in Europe.

Testacea. Wings browniſh; body brown teſtaceous; ſoles of the feet fuſcous. Linn.

Ferruginea. Wings yellowiſh; body ferruginous. Linn.

Stigma. Wings browniſh; body pale yellow; thighs with a black dot in the middle.

Ephemera, is alſo applied among *Botaniſts*, to a kind of flowers which open and expand themſelves at ſunriſing, and wither or cloſe up again at his ſetting. Such are the dent-de-lion, vulgarly dandelion, and divers others.

EPHEMERIDES, in *Aſtronomy*, tables calculated by aſtronomers, ſhewing the preſent ſtate of the heavens for every day at noon; that is, the places wherein all the planets are found at that time.

It is from theſe tables that the eclipſes, conjunctions, and aſpects of the planets are determined; horoſcopes, or celeſtial ſchemes, conſtructed, &c.

We have ephemerides of Regiomontanus from 1475 to 1506, of Engel from 1494 to 1500, of Staeffler from 1499 to 1531, of Origan from 1595 to 1654, of Kepler from 1617 to 1628, of Argoli from 1620 to 1700, of Heckerus from 1666 to 1680, of Wing from 1652 to 1671, of De la Hire from 1701 to 1703, of Manfredi from 1715 to 1750, of Parker, &c. S. Caſſini has calculated ephemerides of the ſidera medicæa, or ſatellites of Jupiter, which are of good uſe in determining the longitude.

In England the Nautical Almanac or Aſtronomical Ephemeris, publiſhed annually by anticipation, under the direction of the Commiſſioners of Longitude, is the moſt conſiderable. See Almanac.

In France they have preſerved in the national library ephemerides of 1442; and celeſtial ephemerides have been publiſhed by M. Deſplaces every ten years, from 1715 to 1745: they were afterwards continued by the abbé Caille, with many additions, from 1731 to 1774, of which an account may be ſeen in the Hiſtory of the Academy of Sciences for 1743, &c.; they were further continued by Lalande from 1775 to 1810. The Academy of Sciences have likewiſe publiſhed annually, from the year 1678, a kind of ephemeris, under the title of Connoiſſance des Tems. This has been continued ſince the revolution under the direction of the "Bureau des Longitudes." The two volumes for the years 8 and 9, edited under the inſpection of M. Lalande, contain, beſides other important articles, new catalogues of the ſtars; tables of the moon's horary motion by Delambre; obſervations of Mercury by Videl, &c. They have alſo ephemerides at Bologna; thoſe for 23 years from 1787 to 1810, being computed by C. Mateucci, aſſiſted by Iſolani, Guglielmini, Sacchetti, Zanotti, and Canterzani. The ephemerides of Milan contain the reſult of an important labour of C. Oriani, on the method of correcting the elements of the tables of Mercury by obſervation, and many intereſting obſervations of C. Reggio and De Ceſaris, &c. &c. The ephemerides of Berlin are now conducted by M. Bode, and contain many aſtronomical obſervations and memoirs by German, French, and Engliſh aſtronomers. The aſtronomers of Vienna commenced a ſimilar work in 1757. The geographical ephemerides, undertaken by M. Von Zach, of Gotha, at the commencement of the year 1798, contain many curious obſervations; information reſpecting new books and charts, new voyages and geographical maps, portraits of eminent philoſophers, and, in a word, every thing that can be intereſting to aſtronomers, geographers, and navigators. The meteorological obſervations of the electoral Academy of Sciences at Manheim, from 1781 to 1792, are comprehended in 12 volumes 4to. under the title of "Ephemerides Societatis Meteorologicæ Palatinæ."

EPHEMERUM, in *Botany*, from εφημερος, laſting but a day, in alluſion to its tranſient bloſſoms; ſee Lysimachia. The name has alſo been given in ancient times to the hemlock, on account of the celerity of its deſtructive action upon animal life.

EPHESIA, in *Mythology*, a feaſt inſtituted at Epheſus, in honour of Diana.

EPHESIANS, Epistle *to*. See Epistle.

EPHESIORUM Portus, in *Ancient Geography*, a port of Aſia Minor, upon the Boſphorus of Thrace; the modern name of which is *Aphoſiati*.

EPHESIUM, the name of a plaſter, which is deſcribed by Celſus.

EPHESIUS, in *Biblical Hiſtory*, a manuſcript of the goſpels written in 1166, and formerly in poſſeſſion of a biſhop of Epheſus, whence it has taken its name. It is noted 71 in the firſt part of Wetſtein's N. T. It is at preſent in the archbiſhop's library at Lambeth, to which it was preſented by Trahern, together with the extracts which he had made from it. Theſe were inſerted by Mill, in his collections of readings.

EPHESTIA, in *Mythology*, a feaſt celebrated in honour of Vulcan, in which three young lads ran for a prize.

EPHESTRIA, were feaſts celebrated at Thebes, in honour of Tyreſias.

EPHESUS, in *Ancient Geography*, a city of Aſia Minor, in Ionia, formerly reputed the metropolis of Aſia. Stephanus ſtyles it "Epiphaneſtata," or moſt illuſtrious. Pliny repreſents it as the ornament of Aſia; and Strabo deſcribes it as the largeſt and moſt frequented emporium of that continent. The ancient city, which was originally a ſmall village, ſtood about 50 miles S. of Smyrna, near the mouth of the river Cayſter, and the ſhore of the Icarian ſea, which is a bay of the Ægean; but its preciſe ſituation cannot be aſcertained, as it was often deſtroyed and rebuilt. Some modern travellers maintain that the ancient city ſtood more to the ſouth than the preſent town, or rather village, which they infer from the ruins that ſtill remain. It was known in ancient times by the names of Alopes, Ortygia, Morges, Smyrna, Trachæa, Samornion, and Ptela. Its name Epheſus is derived, according to Heraclides, from the Greek word *epheſus*, ſignifying permiſſion; becauſe Hercules, as he ſays, permitted the Amazons to live and build a city in that place. Others allege, that Epheſus was the name of the Amazon that founded the city: for Pliny, Juſtin, and Oroſius unanimouſly affirm, that it was built by an Amazon; while others aſcribe the honour to Androclus, the ſon of Codrus, king of Athens, who was the chief of the Ionians that ſettled in Aſia. However this be, it is acknowledged, that the city, which in the Roman times was the metropolis of Aſia, was founded by Lyſimachus; who, having cauſed the ancient city to be demoliſhed, rebuilt a new one, at a vaſt expence, in a place more convenient, and nearer the temple. We learn from Strabo, that when the inhabitants manifeſted a reluctance to quit their ancient habitations, this prince cauſed all the drains, that conveyed the water into the neighbouring fens and the Cayſter, to be privately ſtopped up: ſo that the city on the firſt violent rains that fell was in great part laid under water, and many of the inhabitants were drowned: and he thus conſtrained thoſe who remained to retire into the new city. This new Epheſus was greatly damaged by an earthquake in the reign of Tiberius, but that emperor repaired and adorned it with ſeveral ſtately buildings, of which there are now ſome few ruins that teſtify its exiſtence. The aqueduct, of which a part ſtill ſubſiſts, is generally believed to have been the work of the Greek emperors; the pillars, that ſupport the arches, are of fine marble, and they are higher or lower as the level of the water required. This aqueduct ſerved to convey water into the city from the ſpring of Halitee, mentioned by Pauſanias. The gate, now called for ſome unknown reaſon the gate of perſecution, is remarkable for three bas-reliefs on the mould, of exquiſite taſte. The port, of which many medals have been ſtruck. is at preſent merely an open road, and not much frequented. The Cayſter was formerly navigable, and afforded a ſafe place for ſhips to ride in, but it is now almoſt choaked with ſand. Epheſus is now venerable for nothing but the ruins of palaces, temples, and amphitheatres. It is called by the Turks *Ajaſaluk* (which ſee), or the temple of the moon, from the magnificent ſtructure formerly dedicated to Diana. The church of St. Paul, ſaid to have been founded by the apoſtle, is wholly deſtroyed; the little which remains of that of St. Mark is ſinking to ruin. The only church remaining is that dedicated to St. John, who reſided here, and this is now converted into a Turkiſh moſque. The town is merely a miſerable village, the habitation of herdſmen and farmers, living in low and mean huts, ſheltered from the extremities of weather by mighty maſſes of ruinous walls; the pride and oſtentation of former days, and the emblem in theſe of the tranſient vanity of human glory. All the inhabitants of this once famous city amount not to above 40 or 50 families of Turks, without one Chriſtian family among them; ſo ſtrikingly hath the ſcripture denunciation been fulfilled, that "their candleſtick ſhould be removed out of its place."

The ancient city, whether it was firſt built by Androclus, who conducted the Ionians hither and drove out the Carians and Leleges, by whom this ſituation was occupied before his arrival, or by one Crœſus or Epheſus, long before the Ionic migration, as others maintain, became ſoon the metropolis of Ionia. It was at firſt governed by Androclus and his deſcendants, who aſſumed the royal title, and exerciſed regal authority over the new colony; whence, even in Strabo's time, the poſterity of Androclus were ſtyled kings, and allowed to wear a ſcarlet robe, with a ſceptre, and all the enſigns of royal dignity. In proceſs of time, a ſenate was eſtabliſhed and a new form of government introduced, which continued to the time of Pythagoras, who lived before Cyrus the Great, and was one of the moſt ſavage tyrants whoſe name and character hiſtory records; for having expelled the ſenate and engroſſed the whole power, he filled the city with blood and rapine, not ſparing even thoſe who fled for ſhelter to Diana's temple. His ſucceſſor Pindarus governed the city with a milder ſway; and in his time Epheſus was beſieged by Crœſus, king of Lydia, who adviſed the inhabitants to devote their city to Diana, and in conſequence of their following his counſel, treated them with kindneſs, and reſtored them to their former liberty. The other tyrants of Epheſus, mentioned in hiſtory, are Athenagoras, Comes, Ariſtarchus, and Hegeſias; the laſt of whom was expelled by Alexander, who, having defeated the Perſians on the banks of the Granicus, beſtowed upon Diana all the tributes which the Epheſians had paid to the Perſians, and eſtabliſhed a democracy in the city. After his death, this city became the prey of his ſucceſſors. Lyſimachus took it, and afterwards Antigonus had poſſeſſion of it and plundered it. Epheſus for a little while was reſtored to its ancient ſplendour; but it was always ſubject to the kings of Syria. In the war between Mithridates and the Romans, the Epheſians took part with the former, and by his order maſſacred all the Romans that reſided in the city; for which barbarity they were ſeverely fined, and reduced almoſt to beggary by Sylla, but afterwards treated kindly and ſuffered to live according to their own laws. It was under the reign of the emperor Alexius, father of Anne de Comnena, that the Mahometans made themſelves maſters of Epheſus. The Greeks retook it in 1206, but they loſt it again 1283. At the commencement of the 14th century it became a part of the Turkiſh dominions; and both the place itſelf and its vicinity exhibit melancholy traces of indolence and inactivity. The Epheſians were much addicted to ſuperſtition, ſorcery, and curious arts, as the Scripture ſtyles them (Acts, xix. 19.); whence came the proverb "Epheſian letters," ſignifying all ſorts of ſpells or charms. By theſe Epheſian letters were meant certain obſcure words and incoherent ſentences, which ſuperſtitious bigots uſed to write on their girdles, and even imprint on their feet, and other parts of their bodies. They were alſo noted for their luxury and laſciviouſneſs. See Epheſ. v. 5.

Epheſus, in its relation to eccleſiaſtical hiſtory, may be conſidered, firſt of all, as the abode of many Jews, who obtained the privilege of citizens (Joſeph. Cont. Appian. l. 2.), and afterwards, as the place where St. Paul took up his reſidence for three years (Acts, xx. 31.), where he wrought miracles (Acts, xix. 11. 1 Cor. xvi. 9.), and was reſiſted by the Jews, (Acts, xx. 19.); and where Timothy was biſhop; and where John reſided; and, moreover, as containing one of the ſeven churches, whoſe character and doom are recorded in the book of Revelations, ch. ii.

Ephesus, *Temple of*. See Diana.

EPHETÆ, of εφιημι, *I ſend forth*, in *Antiquity*, a ſort of magiſtrates among the Athenians, inſtituted by king Demophoon, to take cognizance of murder, manſlaughter, and chance-medley.

Their number was one hundred, whereof fifty were Athenians, and fifty Argians: they were not admitted to the poſt till upwards of fifty years of age. Demophoon ſubmitted to be tried by this court, for having unfortunately killed one of his ſubjects by the turn of his horſe, as he was coming from Troy. It ſubſiſted for a conſiderable time in the ſame form; but at length Draco new-modelled it, excluded the Argians, and made it to conſiſt of fifty-one Athenians, each above fifty years of age: Ubbo Emmius de Rep. Athen. ſays, he transferred to them part of the juriſdiction of the Areopagites. See Areopagus.

The occaſion of erecting this court and of admitting the Argives to ſit as judges, is ſaid to have been as follows. Agamemnon, or, as others ſay, Diomedes, returning with his forces from Troy, were driven one night into an Athenian port called Phalerus, and thinking themſelves in an enemy's country, began their uſual practice of ravaging and plundering; upon which the Athenians fell upon and killed a conſiderable number of them. Next morning they found the palladium, or ſtatue of Minerva, which was brought from Troy, lying upon the ground among the ſlain; by which circumſtance they knew that they were their friends the Argives. The oracle having been conſulted, ordered them to give the ſlain an honourable burial in the place where they fell, to build a temple there, dedicated to Minerva, and to ſet up the palladium in it. Immediately after this tranſaction, it was ordered that this court ſhould be erected to try all caſes of perſonal injury and property. It conſiſted of 50 members, who were to be above 50 years of age, men of ſenſe and known probity, and who had power of life and death. Upon its firſt inſtitution Agamemnon inſiſting that there ſhould be an equal number of Athenians and Argives, the Athenians readily agreed to the propoſal.

EPHIALTES, ἐφιάλτης, in *Medicine*, from επι, *upon*, and αλλομαι, *I leap*, is ſynonymous with the Latin *incubus*, and the Engliſh *night-mare*, which ſee.

EPHIALTEUM, in *Ancient Geography*, the moſt northern promontory of the iſle of Rhodes.

EPHIDROSIS, in *Medicine*, from επι, and ιδρως, *ſweat*, a term uſed by the ancient writers to denote the appearance of a ſweat, whether critical or not, and whether general, or on the upper parts of the body only. The modern noſologiſts have conſtituted a *genus* of diſeaſe under this appellation; under which Sauvages compriſes every variety of morbid perſpiration that occurs as a ſymptom of different maladies. He enumerates ſeventeen ſpecies of ephidroſis. See his Noſol. Method, Claſs IX. Gen. 20. Cullen, Gen. 118.

EPHIELIS, in *Botany*, from εφιελις, *a little cup*, or ſomething like it, in a crown or garland, which alludes, happily enough, to the nectary forming a ſort of cup, or crown, within the circle of the corolla. Schreb. 253. Willd. Sp. Pl. v. 2. 328. (Mataiba; Aubl. Guian. v. 1. t. 128. Juſſ. 249.) Claſs and order, *Octandria Monogynia*. Nat. Ord. Near the *Sapindi*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, in five deep, ſpreading, roundiſh, acute ſegments. *Cor.* Petals five, roundiſh, ſpreading, notched, with a ſmall point, and having claws as long as the calyx. Nectary of ten roundiſh hairy ſcales, ſmaller than the petals, two of them affixed to the baſe of each petal. *Stam.* Filaments eight, briſtle-ſhaped, longer than the corolla, inſerted into a gland; anthers roundiſh, with four angles. *Piſt.* Germen ovate, encompaſſed with the gland which bears the ſtamens; ſtyle none; ſtigma obtuſe. *Peric.* Capſule oblong, compreſſed, with a furrow on each ſide, of one cell and two valves. *Seeds* two, kidney-ſhaped, one attached to the middle of each valve, one above the other.

Eſſ. Ch. Calyx in five deep ſegments. Petals five, with claws. Nectary of ten ſcales, two to each petal. Capſule compreſſed, of one cell and two valves. Seeds two, attached to the valves.

The only known ſpecies is E. *fraxinea*, Willd. a tree 50 or 60 feet high, with copious *branches*, of which the central ones are erect, the reſt widely ſpreading. *Leaves* alternate, pinnate, ſmooth; leaflets four or ſix, oppoſite, oval, pointed, entire, bright green, ſometimes eight inches long. *Flowers* on long axillary branching ſtalks, very ſmall, white. It grows in the foreſts of Guiana, flowering in October. Juſſieu ſuſpects this genus may be more akin to the *Leguminoſæ* than to his *Sapindi*, but he obſerves that the fruit requires further inveſtigation.

EPHIPPIA, of επι and ιππος, *horſe*, denoted certain cloths or houſings, which were faſtened on a horſe by a girth or ſurcingle, in ancient Greece, before the uſe of ſaddles were known. They were compoſed of different materials, as leather, cloth, and the ſkins of wild beaſts, and ſometimes adorned with gold, ſilver, and precious ſtones. When theſe coverings were common, it was reckoned more manly to ride without them. Varro boaſts of having rode, when a young man, without a covering to his horſe; and Xenophon reproaches the Perſians becauſe they placed more clothes on the backs of their horſes than on their beds, and gave themſelves more trouble to ſit eaſily than to ride ſkilfully. Theſe coverings were, therefore, for a long time not uſed in war; and the old Germans, who conſidered them as diſgraceful, deſpiſed the Roman cavalry who employed them. (Cæſ. de Bell. Gall. l. iv. 2.) Dion Caſſius (l. lxiii. 14.) ſays, that they were firſt allowed to the Roman cavalry by Nero. But it has been ſuggeſted that this author alludes merely to reviews, at which the cavalry were probably obliged before this time to appear always without them. In the time of Alexander Severus, the horſes of the whole Roman cavalry had beautiful coverings. (Lamprid. Vit. Alex. Severi. c. 50.) Saddles were firſt denominated ephippia, which originally ſignified nothing more than a covering for a horſe. Beckmann Hiſt. Inv. vol. ii. Berenger's Art of Horſemanſhip, vol. i. p. 41. See Saddle.

EPHIPPITES. See Hippurites.

EPHIPPIUM, in *Anatomy*, the excavation in the upper ſurface of the ſphenoid bone, called alſo ſella turcica. See Cranium.

EPHOD, אפד, derived from אפד, *aphad, to clothe*, a ſacerdotal garment, in uſe among the ancient Jews, ſuppoſed to have been a kind of linen alb, or ſurplice, wore by perſons of diſtinction, of various characters; the ſame with what the Latins call ſuper-humerale. 2 Sam. vi. 4. 1 Sam. xxii. 18. 1 Sam. ii. 18.

It is very hard to ſay preciſely what the ephod was; and there is room enough for the interpreters to be divided about it. The only point they are agreed upon is, that it was an upper garment worn over all the reſt, immediately under the pectoral or breaſt-plate. Some hold it had ſleeves, others deny it. The generality agree, that it was very ſhort, though ſome maintain that it hung down to the feet behind.

There were two kinds of ephods; the one, common to all who aſſiſted in the temple, being only made of common linen, mentioned in the firſt book of Samuel, ii. 18; the other, peculiar to the high-prieſt, mentioned Exod. xxviii. 6. 15. to be made of gold, of blue, and of purple, of ſcarlet, and fine twined linen, with cunning work; having two ſhoulder-pieces, with a curious girdle of the ſame matter, and two onyxes, with the names of the children of Iſrael engraved thereon, ſix upon each ſtone. Theſe onyxes were ſet in gold, and ſerved as buttons upon each ſhoulder. As for the ſhape of the ephod, the LXX call it επωμις, which ſignifies that it was worn on the ſhoulders.

Joſephus ſays (Antiq. l. iii. § 5), that it was a cubit long. It conſiſted, as ſome ſuppoſe, of two parts, the one an oblong rectangular piece, hanging down behind from the ſhoulders to the feet; the other a ſhort rectangular piece, which hung down before, the length of a cubit. Theſe two pieces were joined together upon the ſhoulders, with ſome proper faſtening, as loops, buttons, or the like.

It is alſo expreſſed in the ſecond book of Samuel, vi. 14. that upon the removal of the ark of the covenant from the houſe of Obed-Edom, David danced for joy, girt with a linen ephod; whence ſome authors have concluded, that the ephod was alſo a regal garment, worn on ſolemn occaſions. It is probable that the peculiarity of the ephod of the high prieſt did not conſiſt in its being of a different ſhape from that which was worn by other perſons; but in the richneſs of the materials of which it was made, and the fine embroidery and jewels with which it was adorned.

EPHORI, Εφοροι, magiſtrates eſtabliſhed in ancient Sparta, to balance and check the power and authority of the kings; as at Rome, there were tribunes created to controul the power of the conſuls.

The word is formed of the Greek, εφοραω, *intueor*, formed of the prepoſition επι, and the verb οραω, *to ſee*; whence εφορος, *q. d. inſpector, overſeer.*

Lycurgus, being ſenſible that a perfect underſtanding between the prince and the people was the baſis and foundation of both their happineſs, to maintain that good underſtanding, eſtabliſhed ephori, or inſpectors, as a kind of mediators, who ſhould have an eye to the meaſures and conduct on both ſides, and preſerve ſo equal a balance between them, that the regal power ſhould never decline into ſeverity and tyranny, or the liberty of the people run into licentiouſneſs and rebellion.

This is the account of their inſtitution given by Herodotus and Xenophon. (Her. lib. i. Xen. de Rep. Lacedæm.) The authority of the ephori was very great; they preſided in popular aſſemblies, collected their ſuffrages, declared war, made peace, treated with foreign princes, determined the number of forces that ſhould be raiſed, appointed the funds to maintain them, and diſtributed rewards and puniſhments in the name of the ſtate: they likewiſe held a court of juſtice, enquired into the behaviour of all magiſtrates, inſpected the education and conduct of youth, had a particular juriſdiction over the helotes, and by degrees drew the whole adminiſtration into their own hands. On certain occaſions, they expelled, and even put to death the kings; and aboliſhed or ſuſpended the power of the other magiſtrates, calling them to account at pleaſure. Ageſilaus, in the height of all his conqueſts, which even ſtruck terror on the great king of Perſia, ſtopped, and turned back, out of deference to the ephori, when they recalled him.

Some authors deny that the ephori were eſtabliſhed by Lycurgus, dating their origin 130 years after the time of that legiſlator.

Thus Plutarch, in his life of Cleomenes, aſcribes their inſtitution to Theopompus, king of Sparta, which is alſo confirmed by the authority of Ariſtotle. (Polit. lib. v.) The ephori were five in number, and annually choſen by the people out of their own body: though ſome have imagined, that they were at firſt appointed by the kings at their pleaſure, but that afterwards the people obtained the power of electing them. The year was denominated from the firſt election of theſe magiſtrates; and the Lacædemonian armies took their names from the principal ephori, as thoſe of Athens did from their firſt archon. The ephori did not riſe up at the entrance of the kings, as all the other magiſtrates did; and if even the kings offended againſt the laws, the ephori took cognizance of their conduct, and puniſhed them.

EPHORUS, in *Biography*, a Greek orator and hiſtorian, was a native of Cuma or Cyme in Æolia, and flouriſhed about the year 352 B. C. He was a diſciple of Socrates, at whoſe inſtigation he wrote hiſtory; which he commenced after the fabulous periods, with the return of the Heraclidæ into Peloponneſus, and brought down to the 20th year of Philip of Macedon. This work, which was divided into 30 books, was held in eſtimation by the ancients, and is frequently cited by Strabo and other writers; though the hiſtorian is charged with errors and miſrepreſentations, and plagiariſms. Beſides the hiſtory, the loſs of which is regretted, Ephorus wrote ſeveral other books on moral, geographical, and rhetorical ſubjects, none of which are extant, Bayle. Voſſ. Hiſt. Græc. Gen. Biog.

EPHRA, in *Ancient Geography*, a city of Judea, in the half-tribe of Manaſſeh, on this ſide of Jordan. It was ſituated on the frontiers of the tribe of Ephraim; ſuppoſed to have been the ſame with Ophrah. Judg. vi. 11.

EPHRAIM, *Tribe of*, ſo denominated from Ephraim, the grandſon of Joſeph by Aſeneth, the daughter of Potiphar, who was born in Egypt about A. M. 2294, occupied the ſouth ſide of Samaria, and extended, like that of Manaſſeh, from the Mediterranean on the weſt, and the river Jordan on the eaſt; bounded on the ſouth by the territory of Benjamin and part of Dan, and on the north by the half-tribe of Manaſſeh. The extent of this tribe from north to ſouth was about 7 leagues; and though ſome parts were mountainous and rocky, they were covered with trees and good paſture, and the low lands were rich and fertile, and even luxuriant. The cities and towns were numerous, large, and well-peopled. Joſhua was of this tribe; and the ark and tabernacle remained in it at Shiloh for a conſiderable time. After the ſeparation of the 10 tribes, the ſeat of the kingdom of Iſrael being in Ephraim, Ephraim is frequently uſed to ſignify the whole kingdom. The diſtrict belonging to this tribe is called Ephratah. Pſ. cxxxii. 6. (See alſo Judg. xii. 5. 1 Sam. i. 1.) Ephraim was led captive beyond the Euphrates, with all Iſrael, by Salmaneſer, king of Aſſyria, A. M. 3283. B. C. 721.

Ephraim, or *Ephrem*, a city of Ephraim, towards Jordan, whither Jeſus is ſuppoſed to have retired before his paſſion. John, xi. 54.—Alſo, a city of Benjamin, 8 miles from Jeruſalem, according to Euſebius, near the wilderneſs of Judea, in the way from Jeruſalem to Jericho, not far from Bethel.—Alſo, a conſiderable mountain in the tribe of Ephraim, and extending to that of Benjamin, on which ſeveral towns were built.—Alſo, an extenſive foreſt ſituated on the other ſide of Jordan, not far from Mahanaim, where David abode while the battle was fought, in which Abſolom received the due reward of his unnatural rebellion.

EPHRATA, or Dunkard-*Town*, in *Geography*, a village of America, in Lancaſter county, Pennſylvania, on the N.W. ſide of Calico creek, which, joining the Coneſtoga, falls into the Suſquehanna; 12 miles N. of the town of Lancaſter, and more than 40 W. of Philadelphia. It is ſituated in a romantic and ſequeſtered vale, and inhabited by a community of religious people, called "Tunkers," who are moſtly of German deſcent and believers in the doctrine of general redemption. They are very plain in their dreſs and language; and will neither ſwear, nor fight, nor go to law, nor take intereſt for the money they lend. They have many peculiarities; but their inoffenſive manners have occaſioned their being called the harmleſs Tunkers. This ſettlement is called "Tunkers' town," and conſiſts of about 40 buildings, of which three are places of worſhip. They ſubſiſt by cultivating their lands, by attending a printing office, a griſt-mill, a paper-mill, an oil-mill, &c. and the ſiſters by ſpinning, weaving, ſewing, &c. Beſide this congregation at Ephrata, there were, about 30 years ago, ſome few others of this ſect in various parts of Pennſylvania, and in Maryland. The whole community, excluſively of thoſe in Maryland, comprehended upwards of 2000 perſons.

EPHRATAH. See *Tribe of* Ephraim and Bethlehem.

EPHREM, or Ephraim, denominated the *Syrian*, and honoured with the appellation of *Saint*, in *Biography*, was a native of Niſibis in Meſopotamia, and born during the reign of Conſtantine the Great. Devoting himſelf at an early period to the monaſtic life, he ſedulouſly applied to his ſtudies, and to the compoſition of various theological and moral works. Towards the cloſe of his life he reſided at Edeſſa, where he began to diſtinguiſh himſelf by his writings about the year 370, and was ordained deacon, determining not to accept of any higher eccleſiaſtical order. His works were all written in the Syriac language, and ſeveral of them were tranſlated into Greek, with which he does not ſeem to have been acquainted, during his life. He was held in high eſtimation, on account both of his virtues and his writings. From Dr. Aſſemann we learn, that the Syrians gave him the titles of Doctor or Maſter of the whole world, and of their Prophet; and St. Jerome informs us, that his works were ſo much eſteemed as to be publicly read in ſome churches after the Scriptures. Sozomen highly commends them both for ſtyle and ſublimity of ſentiment; which excellencies are ſaid by this father, and alſo St. Jerome, to have been transfuſed into the Greek verſion of them. The ſubjects of theſe works were commentaries upon the Old and New Teſtaments; homilies, or ſermons; exhortations to the monks; controverſial pieces againſt Sabellius, Arius, Apollinaris, the Anomians, and the Novatians; treatiſes of morality; hymns to be ſung in the churches; panegyrics, &c. of which we have an account by Cave, Du Pin, and Lardner. The moſt complete edition of the works of this writer was publiſhed at Rome, by Dr. Joſ. Aſſemann, aſſiſted by father Benedatti, a Jeſuit, and Evodius Aſſemann, biſhop of Apamea; which was begun in 1732, and finiſhed in 1747, in 6 vols. folio, of which three are Syriac and Latin, and the other three Greek and Latin. St. Ephrem died about the year 378, under the reign of the emperor Valens; ordering his funeral to be conducted in a plain manner, and forbidding any eulogium to be delivered on the occaſion, or any monument to be erected to his memory. With the acknowledged and applauded learning of Ephrem, a conſiderable degree of enthuſiaſm and fanaticiſm was blended; but his charitable diſpoſition, which he manifeſted on a variety of occaſions, endeared his name to ſurvivors, and entitles him to honourable remembrance. Cave. Du Pin. Lardner. Jortin. Gen. Biog.

EPHREMI Codex, in *Biblical Hiſtory*, a manuſcript of the New Teſtament, written on vellum, and ſuppoſed to be of very high antiquity. It is "Codex Regius 1905," noted in the catalogue of MSS. in the royal library in Paris IX., and in all the four parts of Wetſtien's Greek Teſtament by the letter C. It is particularly deſcribed by Grieſbach in his "Symbolæ," p. iii.—liv. The firſt part of it contains ſeveral Greek works of Ephrem the Syrian, written over ſome more ancient writings, which had been eraſed, though the traces are ſtill viſible, and in moſt places legible. Theſe more ancient writings were the whole Greek Bible. The New Teſtament has many chaſms, which are ſpecified by Wetſtein. Beſides theſe chaſms, it is in many places illegible. Wetſtein contends that this MS. was written before the year 542, though his arguments are not wholly deciſive. Its readings, like thoſe of all other very ancient MSS., are in favour of the Latin; but no proof can be given that this has been corrupted from the Latin verſion. It has been altered by a critical collector, who, according to Grieſbach, muſt have lived many years after the time in which the MS. was written, and has probably eraſed many of the ancient readings. Kuſter was the firſt who procured extracts from it, and he inſerted them in his edition of Mill's Greek Teſtament. Wetſtein has repeatedly collated it with very great accuracy; and the numerous readings, which he has quoted from it, greatly enhance the value of his edition. A fac-ſimile of the characters of this MS., which is written without accents, is given by Montfaucon in his "Palæographia Græca." It has many marginal notes, written in uncial letters without accents. In this MS. the diſputed, or rather ſpurious verſe, John, v. 4, is written, not in the text, but as a marginal ſcholion. Wetſtein ſuppoſed, that this was one of the MSS. which were collated at Alexandria in 616 with the new Syriac verſion; but though this does not appear to have been the caſe, it is certainly as ancient as the ſeventh century. Wetſtein argues, from a marginal note to Heb. viii. 7, that it was written before the inſtitution of the feaſt of the purification of the virgin Mary, that is, before the year 542. March's Michaelis, vols. ii. and iii.

EPHREMOF, or Yephremof, in *Geography*, a town and diſtrict of Ruſſia, in the government of Tula, ſituated on the river Metcha, falling into the Don.

EPHRON, in *Ancient Geography*, a place of Paleſtine, in the tribe of Judah, about 15 miles from Jeruſalem, according to Euſebius and Jerome.—Alſo, a mountain of Paleſtine, on the confines of the tribes of Judah and Benjamin, according to the book of Joſhua.—Alſo, a large and ſtrong town of Judea, in the half-tribe of Manaſſeh, on the other ſide of Jordan, over-againſt Scythopolis. It was ſituated near the torrent of Jabok. This town was taken and ſacked by Judas Maccabæus, and razed to its foundations.

EPHYDOR, Εφυδωρ, in *Antiquity*, an officer in the Athenian courts of juſtice, who was to provide the plaintiff and defendant with equal water hour-glaſſes. When the glaſs was run out, they were not permitted to ſpeak any farther; and therefore we find them very careful not to loſe or miſpend one drop of their water. Whilſt the laws quoted by them were reciting, or if any other buſineſs happened to intervene, they gave order that the glaſs ſhould be ſtopped. Pott. Archæol. Græc. lib. i. cap. 21. lib. i. p. 118.

EPHYRA, in *Ancient Geography*, a town of Greece, in Theſprotia, a province of Epirus; mentioned by Velleius Paterculus and Strabo; the latter of whom ſays, that it was afterwards called *Cichyrus*.—Alſo, a town of Greece, in the Pelaſgiotide, a country of Theſſaly. This town was alſo called *Cranon*. Steph. Byz.—Alſo, a town of the Peloponneſus, in Arcadia. Steph. Byz.—Alſo, a town of the Peloponneſus, in the territory of Elis, ſituated on the river Selleis. This place was famous for the deadly poiſons which it produced.

EPI, *Gr.* in *Muſic*, a prepoſition, which, like *hyper*, ſignifies *ſupra*, above. We find one of theſe words frequently added to the Greek names of ſome of the intervals of muſic; as

Epi, or hyper, { Diapaſon,
Diapente,
Diateſſaron,
Ditonum, &c.

When we meet with them thus in conjunction, they imply that the voice, in canons, is to follow the dux, or guide an octave, a fifth, a fourth, &c. below it. The third part is to obſerve the ſame rule with reſpect to the ſecond, and the fourth to the third, and ſo on, whatever the number of parts may be.

EPIACUM, in *Ancient Geography*, a town of Albion, in the country of the Brigantes, according to Ptolemy. Camden places it at Elcheſter, on the river Derwent; Horſley at Hexham, in Northumberland; and Baxter ſuppoſes it was originally written Pepiacum, and places it at Papcaſtle, in Cumberland.

EPIALOS, from ηπιος, *gentle*, and ἁλς, *ſea*, in the *Medical Writings of the Ancients*, the name of a fever, in which the patient labours under a preternatural internal heat, while he at the ſame time ſhivers with cold. It has by ſome been called the ſhivering-fever, and the Romans named it quercera. Galen ſays, it proceeds from a putrified acrid phlegm. The word is, by ſome, alſo applied to any gentle fever, or feveriſh complaint; and by others, to the cold or ſhivering fit preceding a fever. Hippocrates calls by this name that peculiar fever which attends young women, whoſe menſes are ſtopped by taking cold, or other accidents.

EPIAULIA, a name which the Greeks gave to the Miller's Song. It is conſtantly confirmed, in inquiries after Greek muſic, that every profeſſion, trade, and occupation, had its peculiar *nome*, tune, or ſong. Rouſſeau, ſo often ſatirical and ſarcaſtic, but who ſeldom aims at pleaſantry, has condeſcended to be jocular upon the Greek name for the miller's tune, by aſking whether the burleſque word *piauler*, (whimpering, whining,) was not derived from the Greek; as the whimpering, whining, and ſquauling of women and brats, who cry and complain a long time in the ſame tone, ſufficiently reſemble the ſong or noiſe of a mill, and, by a metaphor, the miller?

EPIBATÆ, Επιβαται, among the Greeks, marines or ſoldiers who ſerved on board the ſhips of war. They were armed in the ſame manner as the land-forces, only that more of them wore full or heavy armour. Pott. Archæol. Grec. tom. ii. p. 140.

EPIBATERION, a poetical compoſition, in uſe among the ancient Greeks. When any perſon of condition and quality returned home after a long abſence or journey, into another country, he called together his friends and fellow-citizens, and made them a ſpeech, or rehearſed them a copy of verſes, wherein he returned ſolemn thanks to the immortal gods for his happy return; and ended with an addreſs by way of compliment to his fellow-citizens.

Theſe verſes made what the Greeks call επιβατηριον, *epibaterium*, of επιβαινω, *I go abroad*. At going away they had another, called *apobaterium*.

EPIBATERIUM, in *Botany*, from the Greek adjective επιβατηριος, *climbing*. Forſt. Gen. 54. Schreb. 640. Willd. Sp. Pl. v. 4. 397. Juſſ. 285. Claſs and order, *Monoecia Hexandria*. Nat. Ord. *Meniſperma*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth double, deciduous; outer minute, flat, of ſix leaves; inner thrice as large, of three ovate ſpreading leaves. *Cor.* Petals ſix, ſmaller than the inner calyx, roundiſh; three of them external, placed between the calyx-leaves; three internal. *Stam.* Filaments ſix, capillary, incurved, the length of the petals; anthers roundiſh. Female, (on the ſame plant,) *Cal.* and *Cor.* as in the male. *Piſt.* Germens three, ſuperior, nearly globoſe; ſtyles three, minute, incurved; ſtigmas ſpreading, compreſſed. *Peric.* Drupas three, roundiſh, pointed with the permanent ſtyles. *Nut* kidney-ſhaped, compreſſed, ſlightly furrowed.

Eſſ. Ch. Male, Calyx double; the outermoſt of ſix, the inner of three leaves. Petals ſix, in two ſeries. Stamens ſix. Female, Calyx and Corolla as in the male. Styles three. Drupas three, globular, pointed. Nuts ſolitary, kidney-ſhaped.

E. *pendulum* is the only ſpecies deſcribed, a native of the iſland of St. Jago. The *ſtem* is ſhrubby, climbing, with long pendulous branches. *Leaves* alternate, pointing one way, on ſhort foot-ſtalks, oblong, entire, obtuſe with a point, ſmooth and without ribs, about an inch long. *Flowers* minute, pale, on ſolitary, axillary, ſimple ſtalks.

EPIBOMEUM, the name of a canticle in the Greek muſic, which was ſung before the altar.

EPIC POEM, an heroic poem, or a poem reciting ſome great and ſignal tranſactions of a hero; called alſo *epopœia*. This kind of poem is univerſally allowed to be, of all poetical productions, the moſt dignified, and, at the ſame time, the moſt difficult in execution. To contrive a ſtory which ſhall pleaſe and intereſt all readers, by being at once entertaining, important, and inſtructive; to fill it with ſuitable incidents; to enliven it with a variety of characters, and of deſcriptions; and to maintain, in the courſe of a long work, that propriety of ſentiment, and that elevation of ſtyle, which the epic character requires, is unqueſtionably the higheſt effort of poetical genius. Hence it is that ſo few have ſucceeded in the attempt, and that ſtrict critics will hardly allow any other poem to bear the name of epic, except the Iliad and the Æneid.

An epic poem, according to Boſſu, is a diſcourſe invented with art, to form the manners, by inſtructions diſguiſed under the allegory of an important action related in verſe, in a probable, entertaining, and ſurpriſing manner.

This definition, it has been obſerved, would ſuit Æſop's fables, if they were extended, and put into verſe. Accordingly the critic draws a parallel between the conſtruction of one of Æſop's fables and the plan of Homer's Iliad. The firſt thing, he ſays, which a writer of fables, or of heroic poems, does, is to chooſe ſome maxim or point of morality, deſigned to be inculcated in the work. He next invents a general ſtory, or a ſeries of facts, without any names, ſuch as he conceives moſt proper for the illuſtration of his intended moral. Laſtly, he particularizes his ſtory; that is, if he be a fabuliſt, he introduces his dog, his ſheep, and his wolf; and if he be an epic poet, he draws from ancient hiſtory ſome proper names of heroes to be applied to his actors; and thus his plan is completed. This, ſays Dr. Blair, is one of the moſt frigid and abſurd ideas that ever entered into the mind of a critic; nor can any perſon of juſt reflection and taſte ever imagine, that Homer could have proceeded in this manner. No one, indeed, can entertain a doubt that the firſt objects which ſtrike an epic poet are, the hero whom he is to celebrate, and the action, or ſtory, which is to be the ground-work of his poem. "He does not ſit down, like a philoſopher, to form the plan of a treatiſe of morality. His genius is fired by ſome great enterpriſe, which to him appears noble and intereſting; and which, therefore, he pitches upon as worthy of being celebrated in the higheſt ſtrain of poetry. There is no ſubject of this kind, but will always afford ſome general moral inſtruction, ariſing from it naturally. The inſtruction, which Boſſu points out, is certainly ſuggeſted by the Iliad; and there is another which ariſes as naturally, and may juſt as well be aſſigned for the moral of that poem; namely, that Providence avenges thoſe who have ſuffered injuſtice; but that when they allow their reſentment to carry them too far, it brings misfortunes on themſelves. The ſubject of the poem is the wrath of Achilles, cauſed by the injuſtice of Agamemnon. Jupiter avenges Achilles, by giving ſucceſs to the Trojans againſt Agamemnon; but by continuing obſtinate in his reſentment, Achilles loſes his beloved friend Patroclus."

An epic poem is in its nature the recital of ſome illuſtrious enterpriſe in a poetical form. This definition is ſufficiently exact; and hence it appears to comprehend ſeveral other poems beſides the Iliad of Homer, the Æneid of Virgil, and the Jeruſalem of Taſſo; which are, perhaps, the three moſt regular and complete epic works that were ever compoſed. But to exclude all poems from the epic claſs, which are not formed exactly upon the ſame model as theſe, is, ſays Dr. Blair, the pedantry of criticiſm. This writer, therefore, does not ſcruple to claſs ſuch poems, as Milton's Paradiſe Loſt, Lucan's Pharſalia, Statius's Thebaid, Oſſian's Fingal and Temora, Camoen's Luſiad, Voltaire's Henriade, Cambray's Telemachus, Glover's Leonidas, Wilkie's Epigoniad, under the ſame ſpecies of compoſition with the Iliad and Æneid. They are all, undoubtedly, epic; that is, poetical recitals of great adventures, and conſequently belonging to this denomination of poetry.

The epic poem is diſtinguiſhed from comedy, in that the action of the latter is not important, nor is related by the poet, but acted by the perſons introduced for that purpoſe; which circumſtance, likewiſe, diſtinguiſhes it from tragedy. It differs alſo from tragedy in the event, or concluſion; which, in the latter, is generally unfortunate, but ſeldom or ever ſo in the former. See Action.

Nor is it a philoſophical poem, as that of Lucretius, or the Creation of ſir R. Blackmore; nor a treatiſe of agriculture, or the like, as the Georgics of Virgil; thoſe poems not being intended to form the manners: beſide, that the inſtructions they contain are naked, ſimple, and direct, without any diſguiſe or allegory. Which ſecond circumſtance likewiſe diſtinguiſhes it from a treatiſe of morality, written in verſe; or a ſimple hiſtory in verſe: add, that its being confined to one important action, diſtinguiſhes it from a poem which relates all the actions of a perſon's life.

M. de la Motte, indeed, in his controverſy with madam Dacier, on the ſubject of Homer, maintains, that the whole life of a hero may juſtly be made the ſubject of an epic poem: and even that the Lutrin of M. Boileau might paſs for an epic poem; but he ſeemed afterwards to return to the common ſentiment. In effect, the queſtion is not as to the ſenſe which may be annexed to the words epic poem, but the ſenſe which cuſtom has actually annexed to them.

If we had only regard to the etymology of the word epic, of ἔπος, *verſe, poetry*, from εἴπω, *dico, I ſpeak (relate)*, all poems wherein the poet ſpeaks or rehearſes things himſelf, without making the perſons of his poems ſpeak, except at ſecond-hand, as he relates what they ſpoke on this or that occaſion, would be properly epic poems; and ſo there is not an epigram, ſonnet, or madrigal, but would come under that denomination: but this were wild.

In effect, the term epic poem is only attributed to a compoſition whoſe ſubject is great, inſtructive, and ſerious; that only comprehends one ſingle principal event, to which all the reſt refer; which principal action is to be terminated in a certain ſpace of time, ordinarily about a year. It is true, all this is arbitrary; but the ſenſe of all words is ſo too; and in matters of language we muſt be guided by cuſtom.

If M. de la Motte had only pretended, that one might make a fine inſtructive poem on the whole life of a hero, or an agreeable and diverting poem on ſome humorous adventure, all the world would have been on his ſide. But it is enough that cuſtom has not thought good to apply the term epic either to ſubjects of too much extent, and that are crowded with too many incidents no-way connected together; or to burleſque poems, as the Batrachomyomachia of Homer, the Secchia Rapita of Taſſoni, the Défaite de Dulot, the Lutrin of Boileau, the Hudibras of Butler, the Rape of the Lock of Mr. Pope, or the Diſpenſary of Dr. Garth.

Dr. Blair cannot allow with Boſſu and others, that it is the eſſence of an epic poem to be wholly an allegory, or a fable contrived to illuſtrate ſome moral truth; nevertheleſs, he admits, that no poetry is of a more moral nature than this. The effect, however, in promoting virtue is not to be eſtimated by any one maxim or inſtruction, which reſults from the whole ſtory, like the moral of one of Æſop's fables; but from the impreſſion which the parts of the poem ſeparately, as well as the whole taken together, make upon the mind of the reader; from the great examples which it ſets before us, and the high ſentiments with which it warms our hearts. Its propoſed end is to extend our ideas of human perfection, and thus to excite admiration; an end, which can be accompliſhed only by proper repreſentations of heroic deeds and virtuous characters. Epic poems muſt, according to this ſtatement of their object, be favourable to virtue. Moreover, the general ſtrain and ſpirit of epic compoſition ſufficiently mark its diſtinction from the other kinds of poetry. In paſtoral writing, the reigning ideas are innocence and tranquillity; compaſſion is the great object of tragedy; and ridicule the province of comedy. But the predominant character of the epic is admiration excited by heroic actions. It is ſufficiently diſtinguiſhed from hiſtory, both by its poetical form, and the liberty of fiction which it aſſumes. It is a more calm compoſition than tragedy. It admits, nay, requires the pathetic and the violent on particular occaſions; but the pathetic is not its general character. It requires more than any other ſpecies of poetry, a grave, equal, and ſupported dignity. It takes in a greater compaſs of time and action than dramatic writing admits; and thereby allows a more full diſplay of characters. Dramatic writing diſplays characters chiefly by means of ſentiments and paſſions; epic poetry chiefly by means of actions. The emotions which it excites are, therefore, not ſo violent, but they are more prolonged. Theſe, ſays Dr. Blair, are the general characteriſtics of this ſpecies of compoſition.

The epic poem may be conſidered under three heads; firſt, with reſpect to the ſubject, or action; ſecondly, with reſpect to the actors, or characters; and laſtly, with reſpect to the narration of the poet.

The action muſt poſſeſs the following properties; it muſt be one, and entire, great, and intereſting. (See Action and Episode. See alſo Æneid, Iliad, Paradise Lost, &c.) The actors or perſonages introduced in an epic poem muſt be diſcriminated by appropriate and well-ſupported characters; which is denominated by Ariſtotle giving manners to the poem. See Character, in *Poetry*.

If we examine the characters of Milton, we ſhall find that he has introduced all the variety which his fable was capable of receiving. The whole ſpecies of mankind was reſtricted to two perſons at the time to which the ſubject of his poem relates. We have, however, four diſtinct characters in theſe two perſons. We ſee man and woman in the higheſt innocence and perfection, and in the moſt abject ſtate of guilt and infirmity; the two laſt characters are, indeed, very common and obvious, but the two firſt are not only more magnificent, but more novel than any characters either in Virgil or Homer, or indeed in the whole circle of nature. Milton was ſo ſenſible that the ſubject of his poem afforded him but few characters, as to be led to introduce two actors of a fictitious nature, in the perſons of "Sin" and "Death," by which means he has wrought into the body of his fable a very beautiful and well invented allegory. However, it has been thought, that perſons of ſuch a chimerical exiſtence are not proper actors in an epic poem; becauſe there is not that meaſure of probability annexed to them, which is requiſite in writings of this kind.

There is one circumſtance, relating to the principal actors of the Iliad and Æneid, that merits particular notice, becauſe it gives a peculiar beauty to theſe two poems, and was, therefore, contrived with very great judgment. This is the choice for their heroes of perſons nearly related to the people for whom they wrote. Achilles was a Greek, and Æneas the remote founder of Rome. Their countrymen were thus rendered particularly attentive to all the parts of their ſtory, and ſympathized with their heroes in all their adventures. Milton's poem is alſo admirable in this reſpect; ſince it is impoſſible for any of its readers, to whatever nation, country, or people he may belong, not to be related to the perſons who are the principal actors in it; but what is ſtill infinitely more to its advantage, the principal actors in this poem are not only our progenitors, but our repreſentatives. We have an actual intereſt in every thing they do, and no leſs than our utmoſt happineſs is concerned, and lies, as it were, at ſtake in their whole behaviour.

Beſides human actors, there are perſonages of another kind, that uſually occupy no ſmall place in epic poetry; ſuch are the gods, or ſupernatural beings. This conſtitutes what is called the machinery of the epic poem; and it is the moſt nice and difficult part of the ſubject. About the neceſſity and uſe of machinery in an epic compoſition, critics have been divided. The French critics conſider it as eſſential to the conſtitution of an epic poem; and they allege that a poem, though it ſhould poſſeſs every other requiſite, has no pretenſion to be ranked in the epic claſs, unleſs the main action be carried on by the intervention of the gods. This deciſion ſeems to be principally, if not ſolely, founded on a ſuperſtitious reverence for the practice of Homer and Virgil. But, although theſe poets very properly embelliſhed their reſpective ſtory by the traditionary tales and popular legends of their own country, according to which, all the great tranſactions of the heroic times were intermixed with the fables of their deities; does it hence follow, that in other countries, and in other ages, which do not poſſeſs a ſimilar advantage of current ſuperſtition, and popular credulity, epic poetry muſt be confined to antiquated fictions, and fairy tales? Lucan has compoſed a very ſpirited poem, certainly of the epic kind, where neither gods nor ſupernatural beings are at all employed. The author of Leonidas has alſo ſucceeded in an attempt of the ſame kind; and, without doubt, wherever a poet gives us a regular heroic ſtory, well connected in its parts, adorned with characters, and ſupported with proper dignity and elevation, though his agents be every one of them human, he has fulfilled the chief requiſites of this kind of compoſition, and has a juſt title to be claſſed with epic writers. Dr. Blair, whilſt he cannot admit that machinery is indiſpenſibly neceſſary or eſſential to the epic plan, differs from thoſe critics of conſiderable name, who are for wholly excluding it, as inconſiſtent with that probability and impreſſion of reality, which, as they conceive, ſhould prevail in this kind of writing. (See Elem. of Criticiſm, ch. 22.) In epic poetry, where admiration and lofty ideas are ſuppoſed to reign, the marvellous and ſupernatural find, if any where, their proper place. They both enable the poet to aggrandize his ſubject, by means of thoſe auguſt and ſolemn objects which religion introduces into it; and they allow him to enlarge and diverſify his plan, by comprehending within it heaven, and earth, and hell, men and inviſible beings, and the whole circle of the univerſe.

In the uſe, however, of this ſupernatural machinery, a poet ſhould be prudent and temperate. The ſyſtem of the marvellous, which he introduces, ſhould have ſome foundation in the popular belief, ſo that events, which are moſt contrary to the common courſe of nature, may derive from it an air of probability; and he ſhould guard againſt exceſs in the uſe of it. As to allegorical perſonages, fame, diſcord, love, and the like, they form, ſays Dr. Blair, the worſt machinery of any; and though they may ſerve for embelliſhment, they ſhould not be permitted to bear any ſhare in the action of the poem.

With regard to the narration in an epic poem, it is not of any great moment, whether the poet relate the whole ſtory in his own character, or introduce ſome of his perſonages to relate any part of the action that had paſſed before the poem opens. Homer follows one method in his Iliad, and the other in his Odyſſey. Virgil has, in this reſpect, imitated the conduct of the Odyſſey; Taſſo that of the Iliad. Where the ſubject is of great extent, and comprehends the tranſactions of ſeveral years, as in the Odyſſey and the Æneid, the latter method ſeems preferable. When the ſubject is of ſmaller compaſs, and ſhorter duration, as in the Iliad and the Jeruſalem, the poet may, without diſadvantage, relate the whole in his own perſon. It is of very conſiderable importance in the courſe of the narration, that it be perſpicuous, animated, and enriched with all the beauties of poetry. No ſort of compoſition requires more ſtrength, dignity, and fire, than the epic poem. "It is the region," ſays Dr. Blair (Lectures on Rhetoric, &c. vol. iii.) "within which we look for every thing that is ſublime in deſcription, tender in ſentiment, and bold and lively in expreſſion;" and, therefore, though an author's plan ſhould be faultleſs, and his ſtory ever ſo well conducted, yet, if he be feeble, or flat in ſtyle, deſtitute of affecting ſcenes, and deficient in poetical colouring, he can have no ſucceſs. The ornaments which epic poetry admits muſt all be of the grave and chaſte kind. Nothing that is looſe, ludicrous, or affected, finds any place there. All the objects which it preſents ought to be either great, or tender, or pleaſing. Deſcriptions of diſguſting or ſhocking objects ſhould as much as poſſible be avoided; and, therefore, the fable of the Harpies, in the third book of the Æneid, and the allegory of Sin and Death, in the ſecond book of Paradiſe Loſt, had been better omitted in theſe celebrated poems. Mr. Addiſon, in his critique on the Paradiſe Loſt (Spectator, vol. iv.), has introduced ſeveral pertinent remarks on this ſubject. The ſentiments, which in an epic poem are the thoughts and behaviour aſcribed by the author to the perſons whom he introduces, ſhould be conformable to the reſpective characters of theſe perſons, and when this is the caſe they are ſaid to be *juſt*. The ſentiments have likewiſe a relation to *things* as well as to *perſons*, and they are then perfect, when they are adapted to the ſubject. If in either of theſe caſes the poet endeavours to argue or explain, to magnify or diminiſh, to raiſe love or hatred, pity or terror, or any other paſſion, we ought to conſider whether the ſentiments he makes uſe of are proper to thoſe ends. Homer is cenſured by the critics for his defect as to this particular in ſeveral parts of the Iliad and Odyſſey; but candour aſcribes this defect to the times in which he lived. Virgil has excelled all others in the propriety of his ſentiments. Milton is likewiſe commended in this reſpect; and he claims peculiar praiſe from the conſideration, that moſt of his characters lie out of nature, and were to be formed purely by his own invention. The loves of Dido and Æneas are merely copies of what has paſſed between other perſons. Whereas Adam and Eve, before the fall, are a different ſpecies from that of mankind, who are deſcended from them; and no one but a poet of the moſt unbounded invention, and the moſt exquiſite judgment, could have introduced into their converſation and behaviour ſo many apt circumſtances during their ſtate of innocence. An epic poem ſhould abound not only with ſuch thoughts as are natural, but alſo with ſuch as are ſublime. In this reſpect Virgil is inferior to Homer. Indeed, Virgil ſeldom riſes into ſentiments that are aſtoniſhing, where he is not fired by the Iliad. He every where charms and pleaſes us by the force of his own genius; but ſeldom elevates and tranſports us where he does not deduce his hints from Homer. Milton's chief talent, and diſtinguiſhing excellence, lie in the ſublimity of his thoughts. In the greatneſs of his ſentiments he triumphs over all the poets both ancient and modern, Homer only excepted. As ſentiments that are natural and ſublime are always to be purſued in an heroic poem, there are two kinds of thoughts, which ſhould be carefully avoided; the firſt are ſuch as are affected and unnatural, and the ſecond ſuch as are mean and vulgar. In Virgil we meet with little or nothing that reſembles the firſt kind of thought: none of thoſe trifling points and puerilities that often occur in Ovid, none of the epigrammatic turns of Lucan, none of the ſwelling ſentiments that are ſo frequent in Statius and Claudian, and none of the mixed embelliſhments of Taſſo. Every thing is juſt and natural. Milton has ſometimes erred in this reſpect; and it is urged as his apology, that he was infected by the taſte and practice of the age in which he lived. Mean and vulgar thoughts have rendered Homer obnoxious to cenſure; but his advocates have imputed ſentiments of this kind to the age in which he wrote, and to that which he deſcribed, rather than to any imperfection in that divine poet. No blemiſh of this kind is obſervable in Virgil, and Milton is ſeldom chargeable with it.

We have already obſerved, that the language of an heroic poem ſhould be both perſpicuous and ſublime. In proportion as either of theſe two qualities are wanting, the language is imperfect. See farther of the nature of the epic poem under FABLE. For its matter, ſee ACTION. For its form, ſee NARRATION. For its verſification, ſee HEXAMETER. See alſo MANNERS, CHARACTERS, MACHINE, &c. See alſo ÆNEID, ILIAD, TASSO's *Jeruſalem*, CAMOENS' *Luſiad*, FENELON's *Telemachus*, VOLTAIRE's HENRIADE, and MILTON's PARADISE *Loſt*.

EPICAIROS, in *Ancient Geography*, a town of Paleſtine, E. of Jordan. Ptolemy.

EPICARIA, a town of Illyria, in Dalmatia. Ptol.

EPICAU'MA, (from ἐπι, and καιω, *to burn*). See ENCAUMA.

EPICEDION, Επικηδιον, formed of ἐπι, *upon*, and κηδος, *funeral*, in the *Greek and Latin Poetry*, was a funeral eulogy, or a compoſition in proſe or verſe, delivered over the corpſe of a friend or neighbour, commemorative of the virtues of the deceaſed. In celebrating the obſequies of diſtinguiſhed perſons three kinds of funeral diſcourſes were uſed on the occaſion. One, delivered when the friends were aſſembled to perform the laſt mournful offices for the dead, was termed *epicedium;* another, at the rogus, buſtum, or funeral pile, *nænia;* and that inſcribed on the tomb or cenotaph, *epitaphium*. In the early ages of ſociety, the epicedium was generally an extemporaneous effuſion of ſome near relative or affectionate friend, expreſſive of the ſentiments he felt at the loſs, and calculated to excite the common ſympathy of the ſurrounding attendants. Beautiful ſpecimens are given of this ſpecies of poſtobituary reſpect by Virgil in the Æneid: the one (lib. ix.) on the death of Euryalus, and the other (lib. xi.) on the death of Pallas. But in ſubſequent periods, when wealth and luxury had ſupplanted the ſimplicity of nature, and truth of feeling had been obliged by faſhion to yield to the flattery of pomp; the cuſtom, though preſerved, materially differed in its character and form. What once had been the proper expreſſion of undiſſembled eſteem, was changed into a degrading ſyſtem of pageantry and venality. In moſt public funerals, but more eſpecially in thoſe called *vindictivi*, the corpſe, previous to interment, was carried into the forum, attended by a vaſt train of invited or hired followers, when one of the relatives, or ſome orator of eminence, aſcended the roſtrum, and harangued the audience in praiſe of the departed friend or hero. The origin of this cuſtom is attributed to Valerius Publicola, after the expulſion of the regal title. He having honoured the obſequies of his colleague with a funeral oration, ſo pleaſed the vanity of the Roman people, that it ſoon became faſhionable to celebrate the funerals of great or diſtinguiſhed characters with panegyrics, or encomiaſtic orations. The practice became at length ſo popular, that the younger Pliny, in his epiſtle, lib. ii. ep. 1. conſiders it as the laſt, but not the leaſt addition to the happineſs of a great and good man, to have had the enviable honour of being commended at his funeral by the eloquence of the conſul, Tacitus. Nor was this privilege excluſively confined to men; for Livy relates that the Roman matrons, having been extremely liberal and active in raiſing a collection of gold to enable the government to deliver the city from the hands of the Gauls, were allowed, by an act of the ſenate, to have the privilege of epicedia being pronounced at the celebration of their obſequies, equally with the other ſex. The abuſes to which this cuſtom was liable, and to which it actually became in time ſubſervient, are made the ſubjects of juſt complaint, and pointed animadverſion, both by Cicero and Livy; as tending, by the fulſomeneſs of flattery, to weaken the motives to virtue, and by the greater attention which thoſe poſthumous orators paid to the blandiſhments of eloquence, than to the accurate ſtatement of facts, to falſify the page, and corrupt the ſource of hiſtory. For on ſuch occaſions the orator did not fail to extol the deceaſed in the moſt unqualified terms of praiſe, to emblazon his virtues in the moſt brilliant colours, and to place to his credit noble actions which he had never achieved. Particularly when the orator entered on an inveſtigation of the lineage of the party, he ſeldom failed to ally him to ſome patrician family, or dignify his pedigree, by aſſociating with his name ſome of the moſt renowned characters in the commonwealth to illuſtrate and confirm the deſcent, ſo that gradually, by means of theſe miſrepreſentations being recorded, the epicedia tended to obliterate the juſt diſtinctions of conſanguinity, and throw down the barriers of property. From this heathen cuſtom are derived obituary maſſes, oraiſons funebres, and funeral ſermons.

EPICERASTICS, Επικεραϛικα, formed of επι and κεραννυμι, *I moderate*, in *Medicine*, remedies which, by their temperate moiſture, ſoften the acrimony of a humour, and aſſuage the painful ſenſation of a part irritated or afflicted by it; ſuch are the roots of althæa, mallows, liquorice; leaves of lettuce, mallows, water-lily, purſlain; the ſeeds of flax, poppy, &c. See Emollients.

EPICHARMUS, in *Biography*, a native of the iſland of Cos, who flouriſhed in the 5th century, B. C. His father removed him at an early age to Megara, and afterwards to Syracuſe, where he became a diſciple in the Pythagorean ſchool. Being prevented, by the tyranny of Hiero, from aſſuming the public profeſſion of philoſophy, he chiefly applied himſelf to the ſtudy of dramatic poetry, and offended the Pythagoreans, by introducing the doctrines and precepts of Pythagoras upon the ſtage. His comedies were numerous, of which Suidas aſſigns to him 52; but only ſome few fragments remain. He taught a ſchool at Syracuſe, and is ſaid to have invented the two Greek letters θ and χ. He alſo wrote commentaries upon phyſical and medical ſubjects. We have no accurate account of his philoſophical tenets: but ſome of his apophthegms deſerve to be recorded; ſuch are the following: "To die is an evil; but to be dead is no evil." "Every man's natural diſpoſition is his good or evil dæmon." "He who is naturally inclined to good is noble, though his mother was an Ethiopian." "Be ſober in thought, be ſlow in belief; theſe are the ſinews of wiſdom." "The gods ſet up their favours at a price, and induſtry is the purchaſer." "Live ſo as to be prepared either for a long life or a ſhort one." According to Lucian, the life of Epicharmus was prolonged to the age of 97 years. Laert. l. viii. § 78. Suidas. Fabr. Bib. Græc. v. i. p. 676. Brucker's Phil. by Enfield, vol. i.

EPICHIREMA, Επιχειρεμα, in *Logic*, an argumentation, conſiſting of four or more propoſitions, ſome of which are proofs of others.

Thus, that oration of Cicero for Milo may be reduced to the epichirema: "Thoſe who way-lay a man to kill him, it is lawful for him to kill, as is allowed by the laws of nature and nations, and by the practice of the beſt men; but Clodius way-laid Milo with that view, as appears from his forming an ambuſcade before his country-houſe, and from his proviſion of weapons, ſoldiers, &c." Therefore it was lawful for Milo to kill Clodius.

EPICHIROTONIA, among the Athenians. It was ordained by Solon, that once every year the laws ſhould be carefully reviſed and examined; and if any of them were found unſuitable to the preſent ſtate of affairs, they ſhould be repealed. This was called επιχειροτονια των νομων, from the manner of giving their ſuffrages, by *holding up their hands*. See a farther account of this cuſtom in Pott. Archæol. Græc. lib. i. cap. 26. tom. i. p. 142.

EPICHORDIS, from χορδη, *an inteſtine*, in *Anatomy*, a name given by ſome to the meſentery.

EPICHUS, or Tacape (*Gabs*), in *Ancient Geography*, a town of Africa, on the coaſt of the Mediterranean ſea, S. of Tephrura. See Gabs.

EPICITHARISMA, in the *Ancient Muſic*, an air for the cithara, ſaid to be played at the end of dramatic pieces; which, conſequently, muſt have been to Greek plays what a terminating ballet is now to an opera.

EPICLEROS, Επικληρος, among the Athenians, a daughter that had no brothers, and therefore inherited her father's whole eſtate. See Epidicasia.

EPICŒNE, Επικοινοι, in *Grammar*, a term applied to nouns, which, under the ſame gender and termination, mark, indifferently, two kinds of ſexes. See Gender.

Such in Latin, are *aquila*, *veſpertilio*, &c. which ſignify equally a male or a female eagle, or bat.

Grammarians diſtinguiſh between epicœne and common. A noun is ſaid to be common of two kinds, when it may be joined either with a maſculine or a feminine article; and epicœne, when it is always joined to ſome one of the two articles, and yet ſignifies both genders.

EPICOLIC Region, in *Anatomy*, from επι, *upon*, and κοιλιον, *the colon*, that part of the abdomen which is above the colon.

EPICRANIUS, a thin and broad muſcle, covering the ſuperior arched portion of the cranium, and called alſo fronto-occipitalis, and occipito-frontien; or deſcribed as two muſcles by the names of frontalis and occipitalis.

If we deſcribe this as a ſingle muſcle, which we conſider as the moſt natural and correct method, it will belong to the claſs of digaſtric muſcles, or of ſuch as poſſeſs a middle tendon, with fleſhy fibres connected to its two ends. The aponeuroſis is a very broad but thin plane, made up of tendinous fibres, variouſly interwoven, covering the upper part of the cranium, and hence called by Soemmerring galea cranii aponeurotica. It is ſeparated, along the middle, by a narrow interval from the oppoſite muſcle, and it extends externally as far as the ſemicircular line, to which the temporal faſcia is affixed. Its outer ſurface adheres cloſely to the ſcalp, while the inner is much more looſely connected, by a yielding cellular ſubſtance free from fat, to the pericranium. Its edges are inſenſibly continued into the neighbouring cellular ſubſtance.

The frontal portion is a thin flattened layer of muſcular fibres, commencing by a ſemilunar edge from the front of the aponeuroſis, and deſcending in a ſtraight courſe to the eyebrow. Internally it is continuous with the oppoſite muſcle, and detaches a portion of fibres along the ſide of the noſe, to join the compreſſor narium, and levator labii ſuperioris and alæ naſi. It then terminates by joining the orbicularis palpebrarum, through the whole of its upper convexity, and it is alſo connected with the corrugator ſupercilii. The external ſurface of this muſcle is covered by the integuments of the forehead; and its inner ſurface lies on the frontal bone and os naſi.

The occipital portion is not ſo broad as the preceding. Ariſing from the back edge of the aponeuroſis, it is inſerted into the upper part of the external tranſverſe ridge of the occipital bone. It covers the occipital and a little of the temporal bone, and is covered by the ſcalp.

It is very obvious that the occipito-frontalis cannot affect the bones of the head; but it moves the integuments in different directions, in conſequence of the connection between its tendon and the ſcalp. When the frontal and occipital portions act alternately, they draw the common tendon backwards and forwards, and thereby impart conſiderable motion to the whole hairy ſcalp. If they act together, they will render the aponeuroſis tenſe. When the frontal acts ſeparately, it draws up the eyebrow and ſkin of the forehead, and throws the latter into tranſverſe wrinkles. Hence it is concerned in the expreſſion of the countenance, and acts more eſpecially in the gay and joyful emotions, directly antagoniſing the corrugator ſupercilii, which throws the forehead, and particularly the eyebrows, into longitudinal wrinkles. It contributes alſo, by means of its connection with the upper eyelids, to the opening of the eyelids, when we carry that to as great an extent as poſſible. The ſeparate action of the occipital can only produce a ſlight effect on the integuments of the back of the head. Its contraction, however, fixes the aponeuroſis, and renders it a firm point for the contraction of the frontal in raiſing the eyebrow and eyelid. This muſcle, on the whole, is ſtrongly analogous to the panniculus carnoſus of quadrupeds.

EPICRASIS, in *Medicine*, is a gradual evacuation of ill humours in the blood.

EPICRISIS, Επικρισις, in *Rhetoric*, a clear and brief declaration of the ſpeaker's judgment concerning the ſubject in hand. Thus, "ego ſic ſtatuo, in optimo imperatore quatuor has res ineſſe oportere, &c." Voſſ. Rhet. lib. vi. p. 495.

EPICTETI, in *Ancient Geography*, a people, who, according to Strabo, bounded Bithynia on the eaſt. Hence the weſtern part of Phrygia obtained the appellation of "Phrygia Epictetus." In this territory was the ſource of the river Hermus, and the town of Ancyra was ſituated in it, on the frontiers of Myſia.

EPICTETUS, in *Biography*, an eminent Stoic philoſopher, no leſs diſtinguiſhed for his virtues than his wiſdom, was born in a ſervile condition at Hierapolis in Phrygia, and flouriſhed in the firſt century of the Chriſtian era. At an early age he was ſold as a ſlave to Epaphroditus, a celebrated freedman of Nero, to whom Joſephus inſcribed moſt of his works, and who was afterwards put to death by Domitian. Epictetus was lame; and of this infirmity various cauſes have been aſſigned by different writers. Celſus relates, that when his maſter, in order to torture him, ſqueezed his leg very hard, the philoſopher betrayed no ſymptoms of fear, but ſaid very calmly to his tormentor; "You will break my leg;" and when it was broken, he only ſaid with a ſmile, "Did I not tell you that you would break it." Some ſay, that he was born lame; and others aſcribe his lameneſs to the heavy chains with which his maſter loaded him. Epictetus, having, by ſome means which are not recorded, obtained his freedom, retired to a ſmall hut within the city of Rome, where, in an indigent condition, he devoted himſelf to the ſtudy of philoſophy. Having in his retirement acquired a competent knowledge of the principles of the Stoic ſect, and having alſo received inſtructions in rhetoric from Rufus; he became, notwithſtanding his poverty, a popular preceptor of morals. He was an acute and judicious obſerver of manners; his eloquence was ſimple, majeſtic, nervous, and penetrating: his doctrine inculcated the pureſt morals; and his life was an admirable pattern of ſobriety, magnanimity, and the moſt rigid virtue. His reprehenſions of vice were bold and animated; his inſtructions and precepts impreſſive and conciliating; and they were communicated without that dogmatiſm, vanity, and rudeneſs, which were too generally affected by the philoſophers. He was accuſtomed to obſerve, that the ſum of moral inſtruction may be compriſed in two words, *ανεχȣ και απεχȣ*, *i. e.* endure and abſtain, or bear and forbear. Aulus Gellius repreſents him as the greateſt man the ſect of the Stoics ever produced. The tyranny of Domitian, notwithſtanding his extreme poverty and ſingular merit, included him in the number of thoſe philoſophers who were baniſhed from Italy; and to the arbitrary decree of this monſter, he calmly ſubmitted, conſidering himſelf as a citizen of the world, and fully appriſed, that wherever he went he carried his beſt treaſure along with him. At Nicopolis in Epirus, which he choſe as the place of his reſidence, he purſued his deſign of correcting vice and folly by the precepts of philoſophy. The wiſdom and eloquence of his diſcourſes were held in ſuch high eſtimation, that his hearers were very numerous, and it became a common practice among them to commit his inſtructions to writing. It is not certain whether he returned to Rome after the death of Domitian; but the reſpect which Adrian entertained for him renders it probable, that he ſpent the latter part of his life in that city. Here, however, he obtained no favours, that could induce him to abandon that humble condition of contented and independent poverty, which he had ſelected, and in which he determined to remain. Of the time and manner of his death we have no certain account. Themiſtius and Suidas aſſert that he lived till the time of the Antonines; but from the mention that is made of him by Aulus Gellius and Marcus Aurelius, it is probable that he died towards the cloſe of the reign of Adrian. His name and memory were ſo much reſpected after his deceaſe, that, according to Lucian, the earthen lamp, by which he uſed to ſtudy, was ſold for 3000 drachmas, or more than 90*l.* of our money. The teſtimony of Suidas, who aſſerts that Epictetus wrote many books, is not ſupported by any ancient author; however this be, the only remains of this philoſopher are his beautiful moral manual, entitled "Enchiridion," and his "Diſſertations," ſelected by Arrian, which were drawn up from notes taken by his diſciples from his lips. Arrian's account of his life and death is not now extant, Simplicius has left a commentary upon his doctrine, in the eclectic manner. There are alſo various fragments of his wiſdom preſerved by Antoninus, Gellius, Stobæus, and others. Although the doctrine of Epictetus is leſs extravagant than that of any other Stoic, his writings every where breathe the true ſpirit of Stoiciſm. The tenet of the immortality of the ſoul was adopted and maintained by him with a degree of conſiſtency ſuited to a more rational ſyſtem than that of the Stoics, who inculcated a renovation of being in the circuit of events, according to the inevitable order of fate; and his exhortations to contentment and ſubmiſſion to Providence are enforced on much ſounder principles than thoſe of the Stoics. He alſo ſtrenuouſly oppoſed the opinion held by the Stoics in general, concerning the lawfulneſs of ſuicide; and his whole ſyſtem of practical virtues approaches nearer than that of any other inſtructor, unenlightened by revelation, to the purity of Chriſtian morality. We have various editions of the remains of this philoſopher, publiſhed at Leyden in 1670, in 8vo. cum notis variorum; at Utrecht in 1711, in 4to.; at Oxford, in 1740, in 8vo. by Joſeph Simpſon, together with the Table of Cebes, &c.; at London in 1742 by J. Upton, in two volumes 4to. which is the moſt valuable of all. The Enchiridion was publiſhed by C. G. Heyne, in 1776, in 8vo. and, together with Cebes's table, by Schweighauſer, in 1798, 8vo. Theſe have been tranſlated into various languages; but the moſt eſteemed verſion in our country is that by Mrs. Carter, publiſhed in 1758, with notes. Fabr. Bib. Græc. v. iii. Aul. Gell. l. i. c. 2. Arrian, l. i. iii. Lucian in Pereg.

t. iv. Adv. Indoct. lib. ement. t. ii. Brucker's Hiſt. Phil. by Enfield, vol. ii.

EPICUREANS, a ſort of ancient philoſophers, who adhered to the doctrines and opinions of Epicurus. See Epicurus.

The doctrines of Epicurus, as they are ſtated in a juſt, comprehenſive, and elaborate detail by Brucker in his "Hiſtory of Philoſophy," tranſlated and abridged by Dr. Enfield, are arranged under the diſtinct heads of Philoſophy in general, canons or rules of philoſophiſing, Phyſics, and Ethics. Philoſophy is the exerciſe of reaſon in the purſuit and attainment of a happy life; whence it follows, that thoſe ſtudies which conduce neither to the acquiſition nor the enjoyment of happineſs are to be diſmiſſed as of no value. The end of all ſpeculation ought to be, to enable men to judge with certainty what is to be choſen, and what to be avoided, to preſerve themſelves free from pain, and to ſecure health of body and tranquillity of mind. Accordingly, the young ſhould apply to the ſtudy of it without delay, nor ſhould the old be ever weary in the purſuit of it. As nothing ought to be dearer to a philoſopher than truth, he ſhould proſecute it by the moſt direct means, deviſing no fictions himſelf, nor ſuffering himſelf to be impoſed upon by the fictions of others, neither poets, orators, nor logicians; making no other uſe of the rules of rhetoric or grammar, than to enable him to ſpeak or write with accuracy and perſpicuity, and always preferring a plain and ſimple to an ornamented ſtyle. A wiſe man will embrace ſuch tenets, and only ſuch, as are built upon experience, or upon certain and indiſputable axioms. Philoſophy conſiſts of two parts:—phyſics, which reſpect the contemplation of nature; and ethics, which are employed in the regulation of manners. Of theſe, the latter is the moſt important; the knowledge of nature being only neceſſary as a means of promoting the happineſs of life. Philoſophers have added a third part, dialectics; which ought to be rejected, as only productive of thorny diſputes, idle quibbles, and fruitleſs cavilling. In order to facilitate the purſuit of knowledge, a few plain maxims and rules may be uſeful. Truth is of two kinds; that which reſpects real exiſtence, and that which conſiſts in a perfect agreement between the conception of the mind and the nature of things. In order to judge rightly concerning truth, it is neceſſary to uſe ſome criterion, or inſtrument, of judging. This criterion will vary according to the nature of the object which the mind contemplates. In judging of natural and moral objects, the three inſtruments employed are ſenſe, preconception, and paſſion. The maxims, or canons, pertaining to ſenſe, are four: Firſt, that the ſenſes can never be deceived, and conſequently, that every perception of an image, or appearance, is true; that is, that the perception, or ſimple apprehenſion, and its efficient cauſe, the ſpecies or image flowing from the object, really agree. Secondly, opinion, or judgment, is conſequent upon perception, and admits of truth or falſehood. Perceptions, or ſenſations, are the effect of real external *phenomena*; but when the mind judges concerning theſe appearances, the opinion may be either right or wrong. Thirdly, every opinion is to be admitted as true, which is atteſted, or not contradicted, by the evidence of the ſenſes, after a careful and deliberate examination of every circumſtance which can be ſuppoſed to affect the queſtion. Fourthly, an opinion contradicted, or not atteſted by the evidence of the ſenſes, is falſe. Thus, the opinion of a *Plenum* muſt be falſe, becauſe it contradicts the evidence of the ſenſes, which atteſt, that there is ſuch a thing as motion. Concerning the ſecond inſtrument of judgment, *viz.* πρόληψις, or pre-conception, four canons may be laid down. Firſt, that all pre-conceptions are derived from the ſenſes, either by immediate impreſſion, as of an individual man; by enlargement or diminution, as of a giant or dwarf; by reſemblance, as of an unknown city to one which has been ſeen; or by compoſition, as of a centaur. Secondly, pre-conception is neceſſary to enable us to reaſon, inquire, or judge of any thing. Thirdly, pre-conceptions, or univerſal notions, are the principles of all reaſoning and diſcourſe; and we eaſily refer to theſe in comparing one thing with another. If theſe notions be agreeable to nature, and diſtinctly conceived, artificial reaſoning will be unneceſſary. Fourthly, truths, not ſelf-evident, are to be deduced from manifeſt pre-conceptions; or, where the relation of ideas is obſcure, it is to be made evident by the intermediate uſe of ſome acknowledged principle. The third inſtrument, paſſion, or affection, which comprehends pleaſure and pain, admits of the following four evident maxims. Firſt, all pleaſure, to which no pain is annexed, is for its own ſake to be purſued. Secondly, all pain, to which no pleaſure is annexed, is for its own ſake to be avoided. Thirdly, that pleaſure, which either prevents the enjoyment of a greater pleaſure, or produces a greater pain, is to be ſhunned. Fourthly, that pain, which either removes a greater pain, or procures a greater pleaſure, is to be endured. As to the uſe of words, two canons are ſufficient. Firſt, in ſpeaking, uſe terms in common uſe, and in the ſenſe in which they are commonly underſtood. Secondly, in hearing, or reading, attend carefully to the ſignification which the ſpeaker or writer affixes to his terms. Attention to theſe maxims would prevent much obſcurity and confuſion, and terminate many diſputes. By theſe rules Epicurus undertook to conduct his followers into the ſecrets of nature, and to lay open to them the origin of things.

The phyſical doctrine of Epicurus was as follows: Nothing can ever ſpring from nothing, nor can any thing ever return to nothing. The univerſe always exiſted, and will always remain; for there is nothing into which it can be changed. There is nothing in nature, nor can any thing be conceived, beſides body and ſpace. Body is that which poſſeſſes the properties of bulk, figure, reſiſtance, and gravity: it is this alone which can touch and be touched. Space, or *vacuum*, deſtitute of the properties of body, incapable of action or paſſion, is the region which is or may be occupied by body, and which affords it an opportunity of moving freely. The exiſtence of bodies is atteſted by the ſenſes. Space muſt alſo exiſt, in order to allow bodies place in which to move and exiſt; and of their exiſtence and motion we have the certain proof of perception. Beſides body and ſpace, no third nature can be conceived. But the exiſtence of qualities is not precluded, becauſe theſe have no ſubſiſtence except in the body to which they belong. The univerſe, conſiſting of body and ſpace, is infinite. Bodies are infinite in multitude; ſpace is infinite in magnitude. The univerſe is immoveable, becauſe there is no place beyond it into which it can move. It is alſo eternal and immutable, ſince it is liable to neither increaſe nor decreaſe, to production nor decay. Nevertheleſs, the parts of the univerſe are in motion, and are ſubject to change. All bodies conſiſt of parts, which are either themſelves ſimple principles, or may be reſolved into ſuch. Theſe firſt principles, or ſimple atoms, are diviſible by no force, and therefore muſt be immutable. The exiſtence of ſuch atoms is indiſputable, becauſe it is impoſſible that any thing which exiſts ſhould be reduced to nothing. A finite body cannot conſiſt of parts infinite either in magnitude or number; and therefore diviſibility of bodies *in infinitum* is inconceivable. All atoms are of the ſame nature, without any difference in eſſential qualities; and yet it appears, from their different effects upon the ſenſes, that they differ in magnitude, figure, and weight. Atoms exiſt in every poſſible variety of figure; and yet on account of their ſolidity, they are infrangible, or incapable of actual diviſion. Gravity is an eſſential principle of atoms; for being perpetually in motion, or making an effort to move, they muſt be moved by an internal impulſe, which may be called gravity. By this internal force, atoms are carried forward in a direction, which is nearly rectilinear; and whilſt they paſs through free ſpace, their declination from a right line occaſions a caſual concurrence of corpuſcles of different forms. Thus various kinds of curvilinear motion will be produced. Moreover, when one atom is reflected from another, and again repelled by a third, it will acquire a kind of vibratory or tremulous motion. Hence an univerſal agitation will enſue. The principle of gravity, being eſſential to the primary corpuſcles or atoms, theſe muſt have been inceſſantly, and from eternity, in actual motion; and with a velocity, when no obſtacle intervenes, which will cauſe them to paſs through the greateſt imaginable ſpace in the ſmalleſt imaginable portion of time. All atoms are alſo ſuppoſed, whilſt they paſs without reſiſtance through the ſame empty ſpace, to move with equal velocity; and though, by colliſion, their direction may be changed, their velocity is not diminiſhed. Atoms are the elements from which all things are compounded, and into which they are reſolved; and the energy, or principle of motion, which eſſentially belongs to them, is the ſole agent in the operations of nature. Action originates in atoms, and from theſe proceeds to compound bodies. Al the changes which take place in the figure, and other properties of bodies, conſiſt in local motion. Bodies are more or leſs rare, in proportion to the ſize of the vacuities which intercept the ſolid atoms of which they are compoſed. Tranſparency depends partly upon the ſame cauſe, and partly upon the poſition of the vacuities between the particles: for rays of light will paſs eaſily through a denſe body, as glaſs, if its vacuities be placed in a ſtraight line. Hardneſs and ſoftneſs, flexibility, ductility, and other qualities, may be explained in a ſimilar manner. The weight of a body is the reſult of the weight of all its atoms; and ſince gravity is an eſſential property of all atoms, all bodies muſt be heavy; and the only reaſon why ſome bodies appear to have the contrary principle of levity is, that they are driven upwards by the denſer maſs in which they are placed. Heat is the influx of certain ſmall, round, ſoft corpuſcles, which inſinuate themſelves into the pores of bodies in continual ſucceſſion, till by their perpetual action, the parts are ſeparated, and at length the body diſſolved. The ſenſe of heat is the perception of the ſeparation of parts, which were before contiguous. Cold is the influx of certain irregular atoms, whoſe motion is ſlower than that of thoſe which occaſion heat, and their effect the reverſe of the former. Pleaſure and pain, motion and reſt, and even time, are actions of bodies. Production and diſſolution are nothing more than a change of the poſition of atoms, or an increaſe or diminution of the particles of which bodies are compoſed. The world is finite and terminable, and muſt have ſome figure, though this cannot poſſibly be aſcertained. It is not eternal, but began at a certain time to exiſt; for ſince every thing in the world is liable to viciſſitudes of production and decay, the world itſelf muſt partake of them. This may alſo be inferred from the ſhort date of hiſtory, and the late invention of arts.

The formation of the world may be conceived to have happened in the following manner: a finite number of that infinite multitude of atoms, which, with infinite ſpace, conſtitutes the univerſe, falling fortuitouſly into the region of the world, were in conſequence of their innate motion collected into one rude and indigeſted maſs. In this chaos, the heavieſt and largeſt atoms, or collections of atoms, firſt ſubſided, whilſt the ſmaller, and thoſe which from their form would move moſt freely, were driven upwards. Theſe latter, after many reverberations, roſe into the outer region of the world, and formed the heavens. Thoſe atoms, which by their ſize and figure were ſuited to form fiery bodies, collected themſelves into ſtars: thoſe which were not capable of riſing ſo high in the ſphere of the world, being diſturbed by the fiery particles, formed themſelves into air. At length from thoſe which ſubſided was produced the earth. By the action of air, agitated by heat from the heavenly bodies upon the mixed maſs of the earth, its ſmoother and lighter particles were ſeparated from the reſt, and water was produced, which naturally flowed into the loweſt places. In the firſt combination of atoms, which formed the chaos, various ſeeds aroſe, which, being preſerved and nouriſhed by moiſture and heat, afterwards ſprung forth in organized bodies of different kinds. Of the animal productions of the earth, ſome may be conceived to have been produced imperfect, and therefore incapable of life, but others would come forth more perfect. Theſe, after the earth was exhauſted of its ſeminal virtues, would reſpectively continue their ſpecies. The world, thus formed, would be preſerved by the ſame mechanical cauſes which produced it; but by the inceſſant motion of atoms, which alone are ſolid and incorruptible, it would gradually tend to diſſolution. In proceſs of time nothing will remain but ſeparate atoms and infinite ſpace. As atoms are infinite, the number of worlds may alſo be infinite. The earth occupies the middle part of the world; but no point within it is properly the centre of gravity, for all heavy bodies fall in nearly parallel lines. The doctrine of Antipodes, according to the Epicurean philoſophy, is falſe. The figure of the earth is a circular plane; and it is preſerved from falling towards the lower region by the air, with which it is congenial, and upon which therefore it does not preſs; their mutual action deſtroying the effect of gravity. Earthquakes are cauſed by the agitation of internal winds and water, or by the decay or ſudden fall of columns, that ſupport portions of the earth's ſurface. Or, the internal winds may be converted into fires, which may cauſe ſudden and violent eruptions, as in mount Ætna. Waters paſſing out of the ſea into the crevices of the earth, undergo a filtration, by which the particles of ſalt received by them from the bed of the ſea are ſeparated. Foſſils and plants are produced by the motion of atoms, that cauſe the continual tranſpoſition, accretion or diminution of individual bodies. Having no vital principle, they can only be ſaid analogically to live or die. Animals having been once formed, at the beginning of the world, by the caſual conjunction of ſimilar atoms, the production of animal bodies is ſtill continued in a conſiſtent and determinate order. The parts of animals were not originally framed for the uſes to which they are now applied; but, having been accidentally produced, they were afterwards accidentally employed. The eye, for example, was not made for ſeeing, nor the ear for hearing, but the ſoul, being formed within the body at the ſame time with theſe organs, and connected with them, could not avoid making uſe of them in their reſpective functions. The ſoul is a ſubtle corporeal ſubſtance, compoſed of the fineſt atoms; which, by the extreme tenuity of its particles, is able to penetrate the whole body, and to adhere to all its parts. It is compoſed of four diſtinct parts; fire, which cauſes animal heat; an ethereal principle, which is moiſt vapour; air; and a fourth principle, which is the cauſe of ſenſation. Theſe four parts are ſo perfectly combined as to form one ſubtle ſubſtance, which, whilſt it remains in the body, is the cauſe of all its faculties, motions, and paſſions, and which cannot be ſeparated from it, without producing the entire diſſolution of the animal ſyſtem. Different ſenſations are the caſual effects of the different organs, which the ſoul in its union with the body is capable of employing, and of the different properties and qualities of external objects. Theſe become ſenſible by means of certain ſpecies, or images, which are perpetually paſſing like thin films from bodies, in form ſimilar to the ſurfaces of the bodies themſelves, and ſtriking upon organs fitted to receive them. The mind, or intellect, which is endued with the power of thinking, judging, and determining, is formed of particles moſt ſubtle in their nature, and capable of the moſt rapid motion. This intellect is a portion of the ſoul, forming with it one nature, and yet retaining its diſtinct character, which is the power of thinking; the ſuppoſed ſeat of it is the middle of the breaſt, or the heart, which we perceive to be the region of thoſe affections which are excited by cogitation. Thought is produced by ſubtle images, which find their way through the body, and, when they arrive at the intellect, move it to think. The affections and paſſions of the ſoul may be reduced to two, pleaſure and pain. Voluntary motion is the effect of images conveyed to the mind, by which pleaſurable or painful conceptions are formed, and ſubſequent deſires or averſions are produced, which become the immediate ſprings of action. Sleep is produced, when the parts of the ſoul, which are at other times diffuſed through the body, are expreſſed or ſeparated by the action of the air, or of food. Dreams are the effect of images caſually flying about, which from their extreme tenuity penetrate the body and ſtrike upon the mind, exciting an imaginary perception of thoſe things, of which they are images. Death is the privation of ſenſation, in conſequence of the ſeparation of the ſoul from the body; in which caſe, the ſoul is diſperſed into the corpuſcles or atoms of which it was compoſed, and therefore can no longer be capable of thought or perception. The knowledge of things, which belong to the regions above the earth, whether aërial or celeſtial, is to be purſued only for freeing the mind from imaginary fears, and ſettling it in a ſtate of tranquillity. In the heavens, or ethereal regions, the ſun, moon, and ſtars appear to be fiery bodies; or they may be ſmooth mirrors, from which bright fiery particles flowing through the ethereal regions are reflected to the earth; or they may be deep veſſels, containing fires; or they may be circular plates heated like mortar, or ſtones in a furnace. The apparent motion of the heavenly bodies may ariſe from the revolution of the whole heaven in which they are fixed, like nails in a ſolid body: or by the revolution of the bodies themſelves through the heaven as a fluid and permeable medium. The cauſe of this motion may be, either an internal neceſſity in the natures of the bodies themſelves, or the external preſſure of ſome ethereal fluid.

In the univerſe there are, according to Epicurus, without contradiction, divine natures; becauſe nature itſelf has impreſſed the idea of divinity upon the minds of men. The notion is univerſal, nor is it eſtabliſhed by cuſtom, law, or any human inſtitution; but it is the effect of an innate principle, producing univerſal conſent, and therefore it muſt be true. This univerſal notion has probably ariſen from images of the gods, which have caſually made their way into the minds of men in ſleep, and have afterwards been recollected. But it is inconſiſtent with our natural notions of the gods, as happy and immortal beings, to ſuppoſe that they encumber themſelves with the management of the world, or are ſubject to the cares and paſſions which muſt attend ſo great a charge. Hence it is inferred, that the gods have no intercourſe with mankind, nor any concern with the affairs of the world. Nevertheleſs, on account of their excellent nature, they are objects of reverence and worſhip. In their external ſhape the gods reſemble men; and though the place of their reſidence is unknown to mortals, it is without doubt the manſion of perfect purity, tranquillity, and happineſs.

Upon a review of the preceding ſummary of the Epicurean ſyſtem, furniſhed chiefly by Laertius and Lucretius, it muſt appear to be a feeble and ineffectual effort to explain the phenomena of nature upon mechanical principles. With this view Epicurus adopts a variety of wild and fanciful hypotheſes, which evince his incapacity of ſolving the grand problem concerning the origin and formation of the world. But the greateſt defect of this ſyſtem is the attempt of its author to account for all the appearances of nature, even thoſe which reſpect animated and intelligent beings, upon the ſimple principles of matter and motion, without introducing the agency of a Supreme Intelligence, or admitting any other idea of fate, than that of blind neceſſity inherent in every atom, by which it moves in a certain direction. Hence he leaves unexplained thoſe appearances of deſign, which are ſo manifeſt in every part of nature, and abſurdly ſuppoſes, that the eye was not made for ſeeing, nor the ear for hearing. Beſides the idea which he gives of the nature of the gods, whoſe exiſtence he admits, as ſimilar to man; and of their condition, as wholly ſeparate from the world, and enjoying no other felicity except that which ariſes from inactive tranquillity, falls infinitely ſhort of the true conception of Deity, as the intelligent Creator and Governor of the world.

The doctrine of Epicurus concerning nature differs from that of the Stoics, (ſee STOICS,) chiefly in the following particulars: while the latter held God to be the ſoul of the world, diffuſed through univerſal nature, the former admitted no primary intelligent nature into his ſyſtem, but held atoms and ſpace to be the firſt principles of all things; and whilſt the Stoics conceived the active and paſſive principles of nature to be connected by the chain of fate, Epicurus aſcribed every appearance in nature to a fortuitous colliſion and combination of atoms. See ATOMICAL and CORPUSCULAR *Philoſophy*.

The ethics of Epicurus are much leſs exceptionable than his phyſics; of which we may judge from the following ſummary. The end of living, or the ultimate good, which is to be ſought for its own ſake, according to the univerſal opinion of mankind, is happineſs: which men generally fail of attaining, becauſe they form wrong notions of the nature of happineſs, or do not uſe proper means for attaining it. The happineſs, which belongs to man, is that ſtate in which he enjoys as many of the good things, and ſuffers as few of the evils incident to human nature as poſſible, paſſing his days in a ſmooth courſe of permanent tranquillity. Perfect happineſs cannot poſſibly be poſſeſſed without the pleaſure that attends freedom from pain, and the enjoyment of the good things of life. Pleaſure is in its nature good, and ought to be purſued; and pain is in its nature evil, and ſhould be avoided. Beſides, pleaſure or pain is the meaſure of what is good or evil in every object of deſire or averſion. However, pleaſure ought not in every inſtance to be purſued, nor pain to be avoided; but reaſon is to diſtinguiſh

guiſh and compare the nature and degrees of each, that the reſult may be a wiſe choice of that which ſhall appear to be, upon the whole, good. That pleaſure is the firſt good appears from the inclination which every animal, from its firſt birth, diſcovers to purſue pleaſure and avoid pain; and is confirmed by the univerſal experience of mankind, who are incited to action by no other principle, than the deſire of avoiding pain, or obtaining pleaſure. Of pleaſure there are two kinds; one conſiſting in a ſtate of reſt, in which both body and mind are free from pain: the other ariſing from an agreeable agitation of the ſenſes, producing a correſpondent emotion in the ſoul. Upon the former of theſe, the enjoyment of life chiefly depends. Happineſs may, therefore, be ſaid to conſiſt in bodily eaſe and mental tranquillity. It is the office of reaſon to confine the purſuit of pleaſure within the limits of nature, ſo as to attain this happy ſtate; which neither reſembles a rapid torrent, nor a ſtanding pool, but is like a gentle ſtream, that glides ſmoothly and ſilently along. This happy ſtate can only be attained by a prudent care of the body, and a ſteady government of the mind. The diſeaſes of the body are to be prevented by temperance, or cured by medicine, or endured tolerably by patience. Againſt the diſeaſes of the mind philoſophy provides ſufficient antidotes; the virtues are its inſtruments for this purpoſe; the radical ſpring of which is prudence, or wiſdom, and this inſtructs men to free their underſtandings from the clouds of prejudice; to exerciſe temperance and fortitude in the government of themſelves; and to practiſe juſtice toward all others. In a happy life, pleaſure can never be ſeparated from virtue. A prudent man will conſult his natural diſpoſition in the choice of his plan of life. Temperance is that diſcreet regulation of the deſires and paſſions, by which we are enabled to enjoy pleaſures without ſuffering any conſequent inconvenience. They who maintain ſuch a conſtant ſelf-command, as never to be enticed by the proſpect of preſent indulgence to do that which will be productive of evil, obtain the trueſt pleaſure by declining pleaſure. Sobriety, as oppoſed to inebriety and gluttony, teaches men that nature is ſatisfied with a little, and enables them to be contented with ſimple and frugal fare: thus health is preſerved; the offices of life are performed with alertneſs and activity; and the occaſional varieties of a plentiful board acquire an excellent reliſh, and a perſon is prepared to meet every reverſe of fortune without the fear of want. Continence, which is a branch of temperance, prevents the diſeaſes, infamy, remorſe, and puniſhment to which thoſe are expoſed, who indulge themſelves in unlawful amours. Muſic and poetry, which are often employed as incentives to licentious pleaſure, are to be cautiouſly and ſparingly uſed. Gentleneſs, as oppoſed to an iraſcible temper, greatly contributes to the tranquillity and happineſs of life, by preſerving the mind from perturbation, and arming it againſt the aſſaults of calumny and malice. Moderation in the purſuit of honours or riches, is the only ſecurity againſt diſappointment and vexation. A wiſe man will, therefore, prefer the ſimplicity of ruſtic life to the magnificence of courts. As the events of futurity are uncertain, he neither will be elated with confident expectation, nor depreſſed by doubt and deſpair; the one and the other being equally deſtructive of tranquillity. It will contribute to the enjoyment of life, to conſider death as the perfect termination of a happy life, which it becomes us to cloſe like ſatisfied gueſts, neither regretting the paſt, nor anxious for the future. Fortitude, by enabling us to endure pain and baniſh fear, is of great uſe in producing tranquillity. Philoſophy inſtructs us to pay homage to the gods, not through hope or fear, but from veneration of their ſuperior nature. It enables us alſo to conquer the fear of death, by teaching us, that it is no proper object of terror; ſince, whilſt we are, death is not, and when death arrives, we are not; ſo that it concerns neither the living nor the dead. The only evils to be apprehended are bodily pain and diſtreſs of mind. It becomes a wiſe man to endure the former with patience and firmneſs, becauſe, if it be ſlight it may be eaſily borne; and if it be intenſe, it cannot laſt long. Mental diſtreſs commonly ariſes, not from nature, but from opinion; a wiſe man, will, therefore, arm himſelf againſt this kind of ſuffering, by reflecting that the gifts of fortune, the loſs of which he may be inclined to deplore, were never his own, but depended upon circumſtances which he could not command. If, therefore, they happen to leave him, he will endeavour as ſoon as poſſible to obliterate the remembrance of them, by occupying his mind in pleaſant contemplation, and engaging in agreeable avocations. Juſtice reſpects man as living in ſociety, and is the common bond without which no ſociety can ſubſiſt. This virtue, like the reſt, derives its value from its tendency to promote the happineſs of life. It is the intereſt of every individual in a ſtate of ſociety to conform to the laws of juſtice, for in ſociety, the neceſſity of the exerciſe of mutual juſtice, in order to the common enjoyment of the gifts of nature, is the ground of thoſe laws by which it is preſcribed. Nearly allied to juſtice are the virtues of beneficence, compaſſion, gratitude, piety, and friendſhip. He who confers benefits upon others, procures to himſelf the ſatisfaction of ſeeing the ſtream of plenty ſpreading around him from the fountain of his own beneficence; at the ſame time he enjoys the pleaſure of being eſteemed by others. The exerciſe of gratitude, filial affection, and reverence for the gods, is neceſſary, in order to avoid the hatred and contempt of all men. Friendſhips are contracted for the ſake of mutual benefit; but by degrees they ripen into ſuch diſintereſted attachment, that they are continued without any proſpect of advantage. A true friend will partake of the wants and ſorrows of his friend, as if they were his own; if he be in want, he will relieve him; if he be in priſon, he will viſit him; if he be ſick, he will come to him; nay, ſituations may occur, in which he would not ſcruple to die for him. It cannot then be doubted, that friendſhip is one of the moſt uſeful means of procuring a ſecure, tranquil, and happy life.

From the preceding ſummary of the ethics of Epicurus, we may be enabled to refute the cenſures which many writers have paſſed upon him, as the preceptor of luxurious and licentious pleaſures. Theſe cenſures have originated in a miſconception of the nature of that pleaſure which he recommends and juſtifies, and which, in his ſyſtem, is only another name for happineſs. Whilſt the Stoics taught that virtue itſelf is happineſs, Epicurus maintained, that the motive by which men are induced to practiſe virtue is the deſire of happineſs. Both taught, that it is impoſſible to be happy without virtue, and both ſuppoſed virtue to conſiſt in a conformity to nature. Whatever errors and abſurdities may be juſtly charged on the Epicurean ſyſtem, it muſt be allowed that, when candidly and fairly interpreted, it afforded no encouragement to immoral conduct. However, it cannot be denied by its moſt zealous advocates, that by the erroneous repreſentations of the gods, and the diſbelief of providence and the immortality of the ſoul, which this ſyſtem propagated, it ſerved very much to relax the obligations and enfeeble the ſanctions and motives of virtue. This was actually the caſe both at Athens and at Rome, where thoſe who belonged to the ſchool of Epicurus, partly diſſeminating his genuine doctrine and partly perverting it, diſgraced the ſyſtem to which they adhered by the laxity and diſſoluteneſs of their manners. Some indeed have expreſſed a doubt, whether Epicurus himſelf diſbelieved the immortality of the ſoul. (See the notes upon "Cudworth's Intellectual ſyſtem of the Univerſe," ſubjoined by Dr. Moſheim to his Latin tranſlation of that learned work, vol. i. p. 66. 500. vol. ii. p. 1174.) His followers, however, ſeem to have been more explicit on this ſubject; and Moſheim aſſerts (Eccl. Hiſt. v. i. p. 167.) that towards the cloſe of the ſecond century of the Chriſtian era, of all the philoſophers, the Epicureans enjoyed the greateſt reputation, and had undoubtedly the greateſt number of followers, becauſe their opinions tended to encourage the indolent ſecurity of a voluptuous and effeminate life, and to baniſh the remorſe and terrors that haunt vice, and naturally incommode the wicked in their ſenſual purſuits. Hence it is certain, that in the common uſe of the appellation, Epicurean has been underſtood to ſignify an indolent, effeminate, and voluptuous perſon, who only conſults his particular and private pleaſure, without concerning himſelf with any thing ſerious. Accordingly it has been maintained, that there were always two kinds of Epicureans, the rigid and the remiſs. The rigid Epicureans were thoſe who were ſtrictly attached to the ſentiments of Epicurus, and who placed their whole happineſs in the true pleaſures of the mind, reſulting from the practice of virtue. The looſe or remiſs Epicureans, taking the words of that philoſopher in a more groſs ſenſe, placed all their happineſs in corporeal gratifications and pleaſures, in eating, drinking, &c. Thoſe of the former claſs, who were the genuine Epicureans, called the others the "Sophiſts of their ſect." In the "Nouveau Dictionaire Hiſtorique" the reader may find a ſhort account of modern Epicurean ſchools in France, the members of which were more diſtinguiſhed by their literary refinement, poliſhed manners, and luxurious indulgence, than their culture of the genuine doctrine of the Greek philoſopher.

Before we cloſe this article, we ſhall briefly trace the ſubſiſtence and progreſs of the Epicurean ſchool, after the death of its founder. From Epicurus the charge of it devolved upon his friend Hermachus; and it was continued in ſucceſſion by Polyſtratus, Baſilides, Protarchus, and others. The ſect ſubſiſted, in a depraved and degraded ſtate, till the decline of the Roman empire. It entered Rome, indeed, in conſequence of the oppoſition excited againſt it by the Stoics in Greece, under a heavy load of obloquy. This was much increaſed by the vehemence with which Cicero, (De Fin. l. ii. Tuſc. Qu. l. 1. 3. Fam. Ep. xiii. 1. Orat. in Piſon. c. 22.) inveighed againſt this ſect, and by the eaſy credit which he gave to the calumnies induſtriouſly circulated againſt its founder. It was, however, patronized by ſeveral perſons of diſtinction in Rome, and particularly by Atticus, the boſom friend of Cicero. Nevertheleſs, the true doctrine of Epicurus was not fully ſtated by any Roman writer, till Lucretius, with much accuracy of conception and clearneſs of method, as well as with great ſtrength and elegance of diction, unfolded the Epicurean ſyſtem in his poem, "De Rerum Naturâ," "On the Nature of Things." The Epicurean ſect, though much degenerated from the ſimple manners of its founder, continued to flouriſh through a long courſe of years under the Roman emperors. This was owing in part to the freedom of manners which it permitted, and in part to the boldneſs with which it combated ſuperſtition; but principally to the ſtrict union which ſubſiſted among the members of this ſchool, and the implicit deference which they unanimouſly agreed to pay to the doctrines of their maſter. The ſucceſſion of diſciples in this ſect was, as Laertius atteſts (l. x. § 9.) uninterrupted, even when other ſchools began to fail. In many places the doctrine of Epicurus was publicly taught, and at Athens the Epicurean ſchool was endowed with a fixed ſtipend. Among the learned men of this period there were ſome, whoſe whole concern was to tranſmit the tenets and maxims of Epicurus uncorrupted to poſterity; and others, who held the memory of Epicurus in high eſtimation, and in many particulars adopted his doctrine, and who, therefore, may not improperly be ranked in the claſs of Epicureans. The principal of theſe are Pliny the elder, Celſus, Lucian, and Diogenes Laertius. After the revival of letters at a much later period, there were not wanting ſeveral learned men, who, finding little ſatisfaction in the obſcure and ſubtle ſpeculations of metaphyſics, had recourſe to the doctrine of Epicurus, as the true key to the myſteries of nature. The firſt reſtorer of the Epicurean ſyſtem among the moderns was Daniel Sennert, an eminent phyſician of Wittemburg, who flouriſhed at the beginning of the 17th century. Sennert, however, confounded the corpuſcles of the more ancient philoſophers with the atoms of Democritus and Epicurus, and held that each element has primary particles peculiar to itſelf. The ſame doctrine was taught, with ſome inconſiderable variations, by Chryſoſtom Magnenus, profeſſor of medicine in the univerſity of Pavia, who, in the year 1646, publiſhed "A treatiſe on the Life and Philoſophy of Democritus." His ſyſtem is rendered obſcure by an attempt to unite the incompatible dogmas of Epicurus and Ariſtotle. The ableſt and moſt ſucceſsful attempt towards the revival of the phyſical and moral philoſophy of Epicurus was made by Peter Gaſſendi, who, beſides a variety of other learned treatiſes, wrote a life of Epicurus, in which he undertakes to reſcue that philoſopher from the load of calumny under which his memory had lain for many ages, as well as to give a fair and impartial repreſentation of his doctrine. The moſt celebrated followers of Gaſſendi were Francis Bernier, a phyſician of Montpelier, who wrote an "Abridgement of Gaſſendi's Philoſophy," Par. 1678, and Walter Charlton, an Engliſhman, who wrote a treatiſe, entitled "Phyſiologia Epicuro-Gaſſendo-Charletoniana," Lond. 1654, in which he attempts to eſtabliſh natural ſcience upon atomic principles. Indeed, the doctrine of atoms and a vacuum has been embraced by the moſt eminent philoſophers. Huygens applies it to explain the cauſe of gravitation, and Newton admits it into his theory of natural philoſophy. (See Atomical *Philoſophy*.) Diogenes Laertius. l. x. Lucretius de Rerum Natura. Stanley's Hiſt. Phil. part. xiii. Gaſſendus de Vita et Moribus Epicuri. Bayle. art. *Epicurus*. Brucker's Hiſt. Phil. by Enfield.

EPICURUS, in *Biography*, the founder of the ſyſtem deſcribed in the preceding article, was an Athenian, of the Ægean tribe, the ſon of Neocles and Chæreſtrata, perſons of honourable deſcent but reduced condition, and born at Gargettus in the vicinity of Athens, at the beginning of the third year of the 109th olympiad, B. C. 342. Neocles, being reduced to poverty, was ſent with a colony of 2000 Athenian citizens to the iſland of Samos, where he occupied a ſmall farm, and took up the profeſſion of a ſchool-maſter; and where his wife Chæreſtrata performed the arts of incantation and luſtration, for the purpoſe of curing diſeaſes and driving away ſpectres, in which, it is ſaid, ſhe was aſſiſted by her ſon, Epicurus, who furniſhed her with luſtral ſongs for her ſolemn rites. Epicurus remained at Samos and in the neighbouring iſland of Teos, till he was 18 years of age, and then removed, with a view to farther advantage for improvement, to Athens. Upon the death of Alexander, he left Athens, and went to his father at Colophon. Soon afterwards he removed to Mitylene, and after paſſing one year in that city, he reſided for 4 years at Lampſacus. In the 36th year of his age, he returned to Athens. From his 14th year to this time, he was induſtriouſly employed in the ſtudy of philoſophy. At Samos he was inſtructed in the Platonic philoſophy by Pamphilus, as Cicero informs us (De Nat. Deor. l. i. c. 26.), and, as we learn from Clement of Alexandria (Strom. l. i.); he attended in his early years upon Nauſiphanes a Pythagorean, and Pyrrho the ſceptic. During his abode at Athens he could not fail to derive conſiderable benefit from Xenocrates, who taught in the Academy, and from Theophraſtus, who delivered lectures in the Lyceum. His ſyſtem of philoſophy, however, was the reſult of his own reflections, after comparing the doctrines of other ſects. About the 32d year of his age, he opened a ſchool, firſt at Mitylene, and afterwards at Lampſacus; but not ſatisfied with theſe obſcure retreats, he determined to make his appearence on the more public theatre of Athens; and purchaſed for his own uſe, at the expence of 80 minæ, a pleaſant garden, where he taught his ſyſtem of philoſophy. From this circumſtance the Epicureans were denominated "the philoſophers of the garden." During the ſiege of Athens by Demetrius, when Epicurus was 44 years of age, and while the city was diſtreſſed with famine, he is ſaid to have ſupported himſelf and his friends on a ſmall quantity of beans, which he ſhared equally with them. The period in which he introduced his philoſophy was peculiarly favourable for his purpoſe: for in the room of the Socratic philoſophy nothing remained but the ſubtlety and affectation of Stoiciſm, the unnatural ſeverity of the Cynics; or the doctrine of indulgence taught and practiſed by the followers of Ariſtippus. The younger citizens were, therefore, diſpoſed to liſten to a preceptor who ſmoothed the ſtern and wrinkled brow of philoſophy, and, under the notion of conducting his followers to enjoyment in the bower of tranquility, led them, unawares, into the paths of moderation and virtue. This circumſtance rendered his ſchool popular, ſo that diſciples flocked into the garden, not only from different parts of Greece, but from Egypt and Aſia. Seneca, though a Stoic philoſopher, bears this teſtimony to Epicurus (Ep. 21.): "I the more freely quote the excellent maxims of Epicurus, in order to convince thoſe who became his followers from the hope of ſcreening their vices, that to whatever ſect they attach themſelves, they muſt live virtuouſly. Even at the entrance of the garden they will find this inſcription: "The hoſpitable keeper of this manſion, where you will find pleaſure the higheſt good, will preſent you liberally with barley cakes, and water from the ſpring. Theſe gardens will not provoke your appetite by artificial dainties, but ſatisfy it with natural ſupplies. Will you not then be well entertained?" The diſciples of Epicurus were ſo cordially attached to one another, that each individual cheerfully ſupplied the neceſſities of his brother. The friendſhip ſubſiſting in the Epicurean fraternity is deſcribed by Cicero (De Fin. l. i. c. 20.) as unequalled in the hiſtory of mankind; and Valerius Maximus (l. i. c. 8.) relates a memorable example of indiſſoluble friendſhip between Polycrates and Hippoclides, two philoſophers of the garden. Epicurus, that he might not be interrupted in the proſecution of his ſtudies, lived in a ſtate of celibacy; and he exhibited an example of that temperance and continence, which he inculcated on his diſciples. Towards the cloſe of his life, however, his conſtitution was enfeebled, and he was afflicted with the ſtone. When he perceived his end approaching, he wrote a will, in which he bequeathed his garden and its appurtenances to Hermachus, and in ſucceſſion to the future profeſſors of his philoſophy. On the laſt day of his life, he informs his friend Hermachus, that his pain was extreme: but he adds, "All this is counterbalanced by the ſatisfaction of mind, which I derive from the recollection of my diſcourſes and diſcoveries." He concludes with intreating his friend by the affection which he had always manifeſted to him and to philoſophy to take care of the children of Metrodorus. The emperor Marcus Antoninus confirms this account, and further ſays, that Epicurus, in his ſickneſs, relied more upon the recollection of his excellent life, than upon the aid of phyſicians, and inſtead of complaining of his pain, converſed with his friends upon thoſe principles of philoſophy which he had before maintained. At length, finding nature juſt exhauſted, he ordered himſelf to be put into a warm bath, where, after refreſhing himſelf with wine, and exhorting his friends not to forget his doctrines, he expired. His death happened in the ſecond year of the 127th olympiad, or B. C. 271, and in the 72d year of his age. He is ſaid to have written a greater number of original works than any other Grecian philoſopher; but none of them are extant, except a compendium of his doctrine preſerved by Laertius, and ſome few fragments diſperſed among ancient authors. His memory was held in high eſtimation, not only by his immediate followers, but by eminent writers, who diſapproved his philoſophy, but entertained a reſpect for his perſonal merit. Nevertheleſs his character and his philoſophy have been ſeverely cenſured; and the accuſations againſt the Epicurean ſchool have been more or leſs confirmed by men diſtinguiſhed for their wiſdom and virtue: Zeno, Cicero, Plutarch, Galen, and a long train of Chriſtian fathers. But a candid examination of his doctrine and character will obviate many of thoſe charges that have been alleged againſt them, and prove, that though in ſome reſpects this philoſopher is highly cenſurable, in others he has been unjuſtly and too ſeverely condemned. The charge of impiety admits of no refutation. The doctrine of Epicurus concerning nature not only militated againſt the ſuperſtitions of the Athenians, but againſt the agency of a ſupreme deity in the formation and government of the world, and he diveſted the Deity of ſome of his primary attributes. Whilſt he profeſſed the utmoſt contempt for popular ſuperſtitions, the gods, whoſe exiſtence he allowed, were deſtitute of many eſſential characters of divinity, and his piety was of a kind very different from that which is inſpired by juſt notions of Deity. Beſides, it has been ſuggeſted, that his ſentiments concerning the gods were adopted and profeſſed for the purpoſe of avoiding the odium and diſgrace which would have attended a direct avowal of atheiſm. Epicurus has alſo been charged with inſolence and contempt towards other philoſophers: but this ſeems to be ſcarcely compatible with the general air of gentleneſs and civility, which appears in his character. The charge of intemperance and incontinence is unqueſtionably an atrocious calumny. That he was eminent for the contrary virtues has been amply atteſted by Laertius, and alſo by thoſe who were adverſe to his doctrine, particularly Cicero, Plutarch, and Seneca. Epicurus has been with equal injuſtice repreſented as uninſtructed and an enemy to liberal ſcience. "We ought to be thankful to nature," ſays this philoſopher, cited by Stobæus, "for having made thoſe things which are neceſſary, eaſy to be diſcovered, and thoſe things which are difficult to be known, not neceſſary."

The temper and character of Epicurus were altogether the reverſe of thoſe of Zeno and the Stoics; his mode of inſtruction was very different; and his ſchool was eſtabliſhed in direct oppoſition to that of the Stoics; and, therefore, we need not wonder, that he ſhould become the object of detraction and calumny. Beſides, the deſign of his philoſophy and its general principles were very different, and they endeavoured to ſecure their own declining popularity by miſrepreſenting his principles and character, and holding him up to the public as an advocate for infamous pleaſures. For theſe, and ſimilar reaſons, Epicurus encountered the violent oppoſition of the Stoics; and yet he had many friends and followers during his life, and his memory was venerated after his death. His three brothers, Neocles, Chæredamus, and Ariſtobulus, devoted themſelves to the ſtudy of philoſophy, and were ſupported by his liberality. Of his intimate friends the moſt celebrated were Metrodorus, Polyænus, and Hermachus. After his death his birth-day was celebrated by his followers as a feſtival; and they preſerved his image in their rings or cups, or in pictures, which they either carried about their perſons, or hung up in their chambers. Their reverence for his authority was ſuch, that they committed his maxims, and ſome of them the whole body of his inſtructions, to memory; and for a long period, it was deemed a kind of impiety to innovate upon his doctrine: ſo that the Epicureans formed a philoſophical republic, regulated by one judgment, and animated by one ſoul. Laertius, l. x. Brucker's Hiſt. Phil. by Enfield, vol. i.

EPICYCLE, formed of the Greek επι, *upon*, and κυκλος, *circle*, q. d. *a circle on a circle*, in the *Ancient Syſtem of Aſtronomy*, was a ſubordinate orbit, or circle, which moved on the circumference of a larger one, which latter was called the *deferent*. By means of this epicycle, one motion, apparently irregular, was reſolved into two that were circular and uniform; and when the obſerved motion was ſo irregular and complicated as not to be repreſented by one epicycle, the method was to add others, till a nearer approximation was obtained. This ſyſtem owed its origin to a prejudice that ſeems to have been extremely ancient, in favour of uniform and circular motion; and the problem that chiefly occupied the aſtronomers in thoſe times, was to aſſign the proper proportion of the deferent and epicycle which ſhould approximate neareſt to the actual obſervations.

The repreſentation made by this concentric theory of the ſolar inequalities in longitude, was as follows:

Let C (*Plate* XII. *Aſtronomy*, *fig.* 105.) be the centre both of the earth and of the circle F B D, and let H G K be a ſmaller circle, called an epicycle, whoſe centre B moves uniformly in the circumference F B D from weſt to eaſt, or in conſequentia, while the ſun moves alſo uniformly, and with the ſame velocity, in the circumference of the epicycle, in antecedentia in the upper part, but in conſequentia in the lower. If the point G of the epicycle, called the apogee, as being moſt diſtant from the earth, be ſuppoſed, at the beginning of the anomaliſtical revolution, to be placed in the point A of O F produced; and if when it comes to G the arch G H be taken ſimilar to F B, the point H will be the place of the ſun when the centre of the epicycle has moved from F to B. If then in O F, to which B H is parallel, we take O E = B H, and on E, as a centre, with the diſtance E A = C F, deſcribe the circle A H P, the ſun would be ſeen from E to move in this circle equably; for the angle A E H is equal to the angle F C B; but ſeen from C, the centre of the earth, he will appear to move in it inequably, for the angle A C H in the firſt ſemicircle of anomaly, that is, in the paſſage of the ſun from A to P, is always leſs than A E H or F C B: and his true place H will be leſs advanced in longitude than his mean B. When, again, the centre of the epicycle, or the mean place of the ſun, having deſcribed a ſemicircle of the epicycle, will be found in P, the perigee of the orbit A H P, and his mean and true places B and H, will be ſeen from C to coincide as they did in A, the apogee; but in the ſun's paſſage from P to A, that is, in the ſecond ſemicircle of anomaly, his true place H, as ſeen from C, will be always more advanced in longitude than his mean place B; for in this ſemicircle the angle P C H is always greater than P E H in D C B. The angle E H C, or B C H, which is the difference between the mean and true places of the ſun, is called the equation of the orbit, as being that quantity which, added to the true motion A C H of the planet in its orbit A H P, in the firſt ſemicircle of anomaly, and ſubtracted from it in the oppoſite ſemircircle, will render it equal to the mean motion A E H or F C B; and it is evident that the equation, or difference, will be greateſt in N or M, where the centre B of the epicycle is 90° diſtant from either apſis. Any lines drawn from E, the centre of the orbit A H P, to the true place of the ſun in H, and from C the centre of the earth, and of the deferent F B D, to the mean place of the ſun in B, are equally called the line of the mean motion of the ſun, becauſe theſe lines are always parallel, and mark the ſame point in the zodiac; and any line drawn from C to the true place of the ſun is the line of the ſun's true motion.

It was thus that the ancients originally proceeded in their repreſentation of the ſolar inequalities, and the repreſentation ſeemed to be ſufficiently juſtified by obſervation; at leaſt till the days of Tycho Brahe no obſervations had been made with ſufficient accuracy to ſubject it to ſuſpicion. Their ſucceſs alſo, while no lunar inequality, except the ſimple anomaliſtical one, was diſcovered, was equal in the application of the ſame concentric theory to the motions of the moon; and having in two caſes thus ſucceſsfully, by means of one ſubordinate ſphere, or epicycle, reconciled apparent inequality of motion with real uniformity, it was natural to ſuppoſe that other inequalities, though more various and complicated, might be explained in a ſimilar manner, and required only the addition of other epicycles. The ſame method of procedure, therefore, was continued, and every new inequality which obſervation diſcovered was accounted for by a new ſphere, or epicycle, producing it, till the whole number employed in the ſyſtem amounted to 34. Ariſtotle, on narrower examination, found theſe inſufficient, and added to them 22: but ſtill they were deemed inſufficient, and the number was at laſt increaſed to 72; but though it was not till long after the days of Ariſtotle that the theory was carried to ſuch a degree of extravagance, the multiplication of epicycles rendered it, even in his time, almoſt as intricate and complex as the appearances which it was intended to explain. Some examples of this kind occur on the revival of it by Copernicus and Tycho Brahe; and when Hipparchus and Ptolemy introduced excentric orbits, and by means of them ſomewhat diminiſhed the multiplicity of the ſpheres employed by their predeceſſors, they were thought to do a ſignal ſervice to aſtronomy. See EXCENTRIC *Theory*.

What was principally required in theſe theories was to aſcertain in the one the ratio of the excentricity; in the other, the ratio of the ſemi-diameter of the epicycle to the ſemi-diameter of the deferent. If we make the radius of Jupiter's deferent circle to that of the epicycle as 52 to 10, the epicyclical motion ariſing from this conſtruction will very nearly agree with obſervation: only we may obſerve, that the oppoſitions which ſucceed each other near the conſtellation Virgo, are leſs diſtant from one another than thoſe obſerved in the oppoſite part of the heavens; ſo that the centre of the epicycle ſeems to move ſlower in the firſt caſe than in the laſt. To reconcile this with the perfect uniformity of the motion of that centre in the circumference of the deferent circle, the ancient aſtronomers ſaid that the earth was not exactly in the centre of the deferent, but ſo placed that the equable motion of the centre of the epicycle appeared ſlower, becauſe it is then more remote, and after various trials they ſixed on a degree of excentricity for the deferent, which accorded better than any other with the obſervations, and really differed very little from them. Copernicus ſhews that their hypotheſis for Jupiter never deviates more than half a degree from obſervation, if it be properly employed. They found that the epicycle moved round the deferent in $4332\frac{1}{3}$ days, with an equation gradually increaſing to near ſix degrees; ſo that if the place of the epicycle be calculated for a quarter of a revolution from the apogee, at the mean rate of $5'$ a day, it will be found too far advanced by near ten days' motion. See Dr. Small's account of Kepler's diſcoveries, where this ſubject is treated at great length.

EPICYCLOID, in *Geometry*, denotes a curve generated by the revolution of a point of the periphery of a circle, along the convex or concave part of another circle.

A point of the circumference of a circle, proceeding along a plane in a right line, and at the ſame time revolving on its centre, deſcribes a cycloid. And if the generating circle, in lieu of moving on a right line, moves along the circumference of another circle, whether equal or unequal, the curve deſcribed by any point in its circumference is called an epicycloid. Indeed the common cycloid has been ſometimes repreſented as an epicycloid formed by the revolution of a finite circle on an infinite circle.

If the generating circle proceeds along the convexity of the periphery, it is called an upper, or exterior epicycloid; if along the concavity, a lower, or interior epicycloid.

In an epicycloid, the part of the circle the generating point moves along, is called the baſe of the epicycloid: thus in *Plate* V. *Analyſis*, *fig.* 9. D C is the baſe of the epicycloid; V its vertex; V B its axis; D P V half of the exterior epicycloid, made by the revolution of the ſemicircle V L B (which is called the generant) along the convex ſide of the baſe D B; as D P U is the interior epicycloid, formed by the generant's revolving along the concave ſide of the baſe.

The length of any part of the curve, which any given point in the revolving circle has deſcribed from the time it touched the circle whereon it revolved, is to double the verſed ſine of half the arc which all that time touched the quieſcent circle, as the ſum of the diameters of the circles to the ſemidiameter of the quieſcent circle; provided the revolving circle moves upon the convex ſide of the quieſcent circle; but if upon the concave ſide, as the difference of the diameters to the ſemidiameter. Otherwiſe: the circumference of the epicycloid G E F (*fig.* 10.) is to four times the diameter of the generating circle B E, as the ſum of the diameters of the two circles is to that of the baſe, in the former of the caſes above mentioned; but in the ſecond, *e.g. feg*, in the ſame figure, as the difference, &c. In the firſt caſe, if the generating circle be ſuppoſed to have its diameter equal to half that of the baſe, the epicycloid F H E G is equal to 6 B E. In the ſecond caſe, when F I is a quarter of F G, the curve F*eg* will be found equal to 3 F I. When the generating circle is half the baſe-circle, as in *fig.* 11, the epicycloid degenerates into a right line, or the diameter of the baſe. Hence it appears, that in order to deduce the known property of the common cycloid, or that its circumference is equal to four times the diameter of the generating circle, we need only ſuppoſe the baſe-circle to be infinite; an infinite, augmented or diminiſhed by a finite quantity, being always the ſame.

Dr. Halley gives us a general propoſition for the meaſuring of all cycloids and epicycloids: thus, the area of a cycloid, or epicycloid, either primary, or contracted, or prolate, is to the area of the generating circle; and alſo the areas of the parts, generated in thoſe curves, to the areas of analogous ſegments of the circle; as the ſum of double the velocity of the centre, and velocity of the circular motion, to the velocity of the circular motion. The demonſtration hereof, ſee in Phil. Tranſ. N° 218.

The areas of epicycloids may be determined by the following proportion: as the radius of the circle of the baſe to three times that radius together with twice that of the generating circle, ſo is the circular ſegment *b* H to the epicycloidal ſector *b* H F, or the whole generating circle to the whole area of the epicycloid F E G B. As to the tangents, it is known from the time of Des Cartes, that the line H *b*, drawn from any point H, to that of the baſe which touches the circle, whilſt this point is deſcribed, is perpendicular to the curve, and conſequently to the tangent. Maupertuis in diſcuſſing this ſubject, conceived a polygon to revolve upon another, the ſides of which are reſpectively equal, one of the angles deſcribed a curve, the periphery of which is formed of arcs of circles, and the area is compoſed of circular ſectors and right-lined triangles. He determined the proportion of the area and of the periphery of this figure to thoſe of the generating polygon. He moreover ſuppoſed theſe polygons to become circles, the figure deſcribed to become an epicycloid; and the above-mentioned proportion, modified agreeably to this ſuppoſition, gave him the area and the periphery of the epicycloid. Mem. de l'Acad. 1727.

The invention of epicycloids is aſcribed to M. Roemer, the celebrated Daniſh aſtronomer, during his reſidence at Paris, about the year 1674. Theſe curves appeared to him to be ſuch as beſt ſuited the teeth of wheels, conſtructed ſo as to diminiſh their mutual friction, and to render the action of the power more uniform; hence he was led to conſider them, and to this purpoſe they have been applied. However, M. de la Hire in his "Traité des Epicycloides," printed in 1694, makes no mention of Roemer, and ſeems to claim the merit of this geometrical and mechanical invention. But M. Leibnitz, who reſided at Paris in 1674 and the two following years, ſays, that the invention of epicvloids, and their application to mechanics, were the work of this Daniſh mathematician, and that he was eſteemed the author of it. It does not appear that any writer publiſhed an account of epicycloids before the celebrated Newton, who, in the firſt book of his "Principia" propoſed a general and very ſimple method of rectifying theſe curves. After him J. Bernouilli, during his reſidence at Paris, ſhewed how, by means of the integral and differential calculus, to determine their area, rectification, &c. Many of his "Leçons du calcul integral" are devoted to this object. In 1694, M. de la Hire publiſhed his "Traité des Epicycloides;" and in the "Memoires of the Academy for 1706" he communicated to the public an extenſive and elegant treatiſe on theſe curves.

Spherical epicycloids are formed by a point of the revolving circle, when its plane makes an invariable angle with the plane of the circle on which it revolves. Meſſrs. Bernouilli, Maupertuis, Nicole, and Clairaut, have demonſtrated ſeveral properties of theſe epicycloids, in Hiſt. Acad. Sc. for 1732.

Epicycloids, *Parabolic*, *Elliptic*, &c. If a parabola be made to revolve upon another equal to it, its focus will deſcribe a right line perpendicular to the axis of the quieſcent parabola; the vertex of the revolving parabola will alſo deſcribe the ciſſoid of Diocles; and any other point of it will deſcribe ſome one of Newton's defective hyperbolas, having a double point in the like point of the quieſcent parabola. In like manner, if an ellipſe revolve upon another ellipſe equal and ſimilar to it, its focus will deſcribe a circle, whoſe centre is in the other focus, and conſequently, the radius is equal to the axis of the ellipſe; and any other point in the plane of the ellipſe will deſcribe a line of the 4th order. The ſame may alſo be ſaid of an hyperbola, revolving upon another, equal and ſimilar to it; for one of the foci will deſcribe a circle, having its centre in the other focus, and the radius will be the principal axis of the hyperbola; and any other point of the hyperbola will deſcribe a line of the 4th order. Concerning theſe lines, ſee Newton's Principia, lib. i. De la Hire's Memoires de Mathematique, &c. where he ſhews the nature of the epicycloid and its uſe in mechanics. See alſo Maclaurin's Geometria Organica. For the method of forming the epicycloidal teeth of wheels, ſee Wheel.

EPICYEMA, from κυω, *I conceive*, a word uſed by Hippocrates to ſignify a fœtus, or a falſe conception, or mole coming on after the conception of a former or regular fœtus.

EPIDAMNUS, in *Ancient Geography*, a town of Illyria, upon a ſmall promontory between Nymphæum and Petra, built by the Corcyreans. Its name, which the Romans conſidered as inauſpicious, was afterwards changed into Dyrrhaicum, now *Durazzo*, which ſee.

EPIDAURIA, Επιδαυρια, in *Antiquity*, a feſtival celebrated by the Athenians, in honour of Eſculapius. See Æsculapius.

EPIDAURUS, in *Ancient Geography*, a town of Greece, in the ancient kingdom of Argos, mentioned by Homer in the enumeration of its ſhips, and which he repreſents as fertile in the production of vines. It was ſituated on the eaſtern coaſt of the peninſula of the Argolide, near the Saronic gulf, and oppoſite to the iſland of Ægina. This town was celebrated among the ancients for the temple of Æſculapius, ſituated about a mile from the river, whither the inhabitants of moſt parts of Europe and Aſia reſorted for the cure of all diſtempers. It is pretended that this was the birth-place of Eſculapius. (See Æsculapius.) Antoninus Pius, after having been adopted by Adrian, conſtructed in this place a temple dedicated to the deities called "Epidotes," and another dedicated to the goddeſs of health, to Eſculapius, and to Apollo, ſurnamed the "Egyptian." He moreover built a houſe, for the accommodation of perſons who inhabited the diſtrict conſecrated to Eſculapius, and alſo for lying-in women. He alſo re-eſtabliſhed the portico of Cotys, which had been demoliſhed. The grove of Eſculapius near this town was encloſed by two mountains, one called "Titthion," and the other "Cynortion," upon which was conſtructed a temple dedicated to Apollo Maleates, and upon its ſummit another dedicated to Diana Coryphæa. In a rotundo near this town were preſerved ſome curious pieces of painting, the performances of Pauſias, a famous painter of Sicyone, and contemporary of Apelles. The Epidaurians had a beautiful theatre in the temple of Eſculapius, conſtructed by Polycletus, who alſo built the rotundo at the entrance of the town. Bacchus and Venus had alſo temples in this town. Epidaurus was alſo famous for its temple of Diana the Huntreſs, and a grove conſecrated to her, in which was a ſtatue of Epione, ſuppoſed to be the wife of Eſculapius. In this grove was a ſuperb fountain, ſplendidly ornamented. In the citadel of the town was a very beautiful ſtatue of wood, which repreſented Minerva, denominated by the Epidaurians "Ciſſea." The temple, dedicated to Juno, was on the ſide of the port, on a promontory which commanded a view of the ſea. The Dorians, having been driven from this town by Deiphon and the Argians, united with the Ionians and with them inhabited the iſlands of Samos and Chios. Epidaurus is now a ſmall place, called "Pidavra."

Epidaurus *Limera*, or *Epidaurus Malvaſia Vecchia*, *i. e.* the ancient Malvoiſia, is a port of Laconia, ſeated on the gulf of Argos, now "Golfo di Napoli," S. E. of Zarex. It is pretended that this place was founded by a colony of Epidaurians from the Argolide. Having embarked, as it is ſaid, for the iſland of Cos, they were driven by contrary winds on this coaſt of Laconia. They were cautioned in a dream from ſettling here; but a ſerpent which they brought with them left the ſhip and conducted them to the land. This fable was credited in the country, and the worſhip of Eſculapius was eſtabliſhed along this whole coaſt. The Epidaurians thus contrived to obtain a conſiderable part of the wealth which ſuperſtition had accumulated in the Epidaurus of the Argolide: and hence the new town acquired the appellation annexed to it. It was denominated *Limera*, *i. e.* famiſhed, a name which was not improperly applied to a town, the inhabitants of which contrived to exiſt at the charge of another. It was built upon an eminence, at the bottom of a ſmall gulf; it was well-peopled, and was famous among other things for its excellent wine, called Malveſy or Malmeſy, which grew round the vicinity of it, and with which it ſupplied other parts of Greece. The moſt remarkable objects of this place in the time of Pauſanias were two temples; one of Venus, another of Eſculapius, with a ſtatue of this god. Its port was honoured with the appellation of the "Port of Jupiter Conſervator."

Epidaurus, a town of Illyria, in Dalmatia, according to Ptolemy and Pliny, the latter of whom gives it the title of a colony; in whoſe time it was joined to the continent, though, as he ſays, it had formerly been an iſland. It is now "Raguſi-Vecchio."

EPIDELICUM, a town of Laconia, on the Argolic gulf, S. E. of Epidaurus.

EPIDELOS, a word uſed by Hippocrates for a youth in the time of his growth, from the age of ſeven to that of fourteen. The ſame author alſo uſes it in a very different ſenſe, expreſſing by it the obſervable days in a diſeaſe, ſuch as the fourth, eighth, and eleventh, which indicate what ſort of criſis is to be reaſonably expected on the great critical day.

EPIDEMIA, Επιδημια, in *Antiquity*, feaſts of Apollo, at Delphos, and Miletus; and of Diana, at Argos.

Theſe feaſts bore the name epidemia (from επι, *in*, and δημος, *people*,) becauſe theſe gods were imagined to be preſent on thoſe days among the people. Accordingly, on the laſt day of the epidemia they ſung an hymn called αποπεμπτικος, to bid them adieu, and ſet them forwards on their journey.

As thoſe gods could not be every where, and yet were honoured in many different places, there were times allowed them to paſs from one place to another, to receive the vows of their adorers. See Scaliger, Poet. lib. iii. cap. 114.

Epidemia were alſo private feſtivals, and times of rejoicing, when a friend or relation had returned from a journey. Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

EPIDEMIC Diseases, from ἐπι, and δημος, *the people*, are thoſe diſeaſes which prevail extenſively, at different times and ſeaſons, among the inhabitants of cities, or countries: when they occaſion great mortality among the perſons ſeized; they are termed *peſtilential*.

The diſeaſes, which are liable to occur epidemically, or to attack a great number of individuals about the ſame time, or in rapid ſucceſſion, are principally thoſe of the acute or febrile claſs. Thus the plague, the ſweating ſickneſs, the yellow fever, contagious fever, or typhus, intermittent and remittent fevers, ſcarlet fever, ſmall-pox, meaſles, dyſentery, catarrh, (denominated influenza under ſuch circumſtances,) ophthalmia, hooping cough, &c. are the diſeaſes which have at different times ſpread over extenſive diſtricts epidemically, ſome of them occaſioning the moſt deſtructive mortality. Of theſe the influenza, or epidemic catarrh, appears to be the moſt extenſive in the range which it takes, and the moſt independent of local cauſes: in ſome inſtances, as in the years 1781 and 1782, this diſeaſe appears to have originated in China, and thence to have ſpread through Aſia, to Europe, and in the year following to have viſited America.

The other fatal epidemics, ſuch as the plague, yellow fever, and ſmall-pox have been in general the calamities more particularly, though not excluſively, connected with large towns, camps, or other congregations of men. Some of theſe diſeaſes, as the plague and ſweating ſickneſs, are ſcarcely known except as epidemical; and are altogether unknown, but as diſeaſes of a malignant and fatal tendency: but many of the others, as ſmall-pox, meaſles, ſcarlet fever, and typhus, are common and familiar appearances, which ſeldom ceaſe to exiſt among us; but which, nevertheleſs, only occaſionally aſſume thoſe fearful and fatal characters, which belong to them as epidemics.

No circumſtance, connected with diſeaſes, has been the ſubject of more general inquiry, among the phyſicians of all ages, than this variation in their tendency to ſpread at one time to multitudes of individuals, to put on a malignant character, and to prove generally deſtructive; whilſt at others they exiſt in milder forms, affecting few, and deſtroying ſcarcely any. Yet the moſt comprehenſive views of the concomitant circumſtances, in regard to the obvious conditions of the ſeaſons, and of the moral and political ſtate of the diſtricts, where epidemic diſeaſes ariſe or diſappear, continued with the moſt minute obſervation during a ſucceſſion of ſeaſons, have failed to elucidate ſatisfactorily this intereſting topic. Hippocrates, who has noted with accuracy the peculiarities of various years, together with the prevalent ſpecies of diſeaſe, attributes the variation of the maladies to a divine ſomething, τὸ θεῖον; which ſome of his commentators conſider as ſignifying merely the atmoſphere at large; but others, among whom is Galen, ſuppoſe that he intended to expreſs a latent and inſcrutable cauſe in the air, which produced theſe ſurpriſing effects. (See Hippoc. lib. i. de Prognoſt. Galen in Com,—alſo, Sennert. lib. iv. cap. ii. de Cauſis Peſtilentiæ.) Galen obſerves, in his commentary upon this point, "non quæcunque cauſas habent abditas et obſcuras, *divina* vocamus; ſed ubi admirabilia videntur duntaxat." The modern Hippocrates, Sydenham, ſtates, that he had obſerved with the utmoſt diligence the different peculiarities of different years, as to the obvious changes and conditions of the atmoſphere, with a view to aſcertain the cauſes of the great varieties of epidemic diſorders; but that he had not made the ſmalleſt approximation to ſuch a diſcovery; on the contrary, that he had remarked, that ſeaſons of the moſt decided ſimilarity, in reſpect to the manifeſt qualities of the air, were infeſted by diſeaſes altogether diſſimilar; and *vice verſâ.* "For the *conſtitutions* of different years are various;" he ſays, "yet they do not depend upon the degree of heat or cold, of dryneſs or humidity, which accompanies them; but probably originate from ſome occult and inexplicable changes, wrought in the bowels of the earth itſelf, by which the atmoſphere is contaminated with certain effluvia, which prediſpoſe the bodies of men to one or other form of diſeaſe. This prediſpoſition continues during the prevalence of the ſame conſtitution, which, in an uncertain period of time, is ſuperſeded by another." (Sydenham, ſect. i. cap. 2. De Morbis Epidem. See alſo Van Swieten Comment. ad Aph. 1408.)

From a conſideration of the ſame facts, ſeveral writers have attempted to account for theſe ſuppoſed occult changes in the qualities of the atmoſphere, which induce epidemic diſeaſes, by tracing them to ſome of the obvious phenomena of nature, by which ſuch changes may be ſuppoſed to be effected. Thus a coincidence has been attempted to be traced between the appearance of comets and of meteors, the occurrence of earthquakes, the eruptions of volcanoes, the conjunction of certain planets, &c.; by all of which it is preſumed that ſome important operations are accompliſhed in the condition of our atmoſphere. Of the effects of planetary influence, indeed, in inducing or diminiſhing the morbific qualities of the air, nothing is to be found in the writings of the preſent times: the hypotheſis originated and has gone by with the age of aſtrology. But a very late writer has filled two volumes with evidence, which he believes goes far to prove the exiſtence and operation of ſome general agent, or *peſtilential principle,* throughout the phyſical world. To this agent he aſcribes the origin of earthquakes, and volcanoes, and meteors; and he ſeems to conſider it as the medium by which comets affect the earth, producing tempeſtuous ſeaſons, great heats, and great colds. (See a brief Hiſtory of Epidemical and Peſtilential Diſeaſes, by Noah Webſter, 1800.) This, as a mere hypotheſis, would be ſcarcely leſs viſionary and futile, than the ſuppoſition of planetary influence, juſt noticed. Mr. Webſter, therefore, has collected, with great induſtry, an hiſtorical account of the various epidemic and peſtilential viſitations on record, which have ſucceſſively occurred to different countries, and has connected with it a chronological view of the appearance of comets, the eruptions of volcanoes, the commotions of the earth, and of the various atmoſpheric phenomena, which have been deſcribed by authors in order to prove their coincidence. "It is certain," we are told, "that comets have a very ſenſible effect on the weather;" (loc. cit. vol. ii. p. 122.) and Ariſtotle, Pliny, and Seneca, are quoted to prove that great heat, tides, and winds, are among the general concomitants of comets. "All the comets," Mr. W. affirms, "which have approached this earth, in their paſſage to and from the ſun, eſpecially thoſe which have paſſed very near us, have been preceded, attended and followed by moſt extraordinary effects, as great heat and drought in ſummer, and ſevere cold in winter; deluging rains, violent tempeſts, and unuſual tides. They occur ſo uniformly, with the appearance of theſe bodies, and for ſome months preceding and following, as to leave no room to queſtion the influence from which they proceed." Ibid. Whatever may occaſion extreme variations in the condition of the atmoſpheric temperature, produce inundations, dearth, &c. will thus remotely, no doubt, induce epidemic diſeaſes, as will be ſhewn in the ſequel. A great number of records are quoted by Mr. Webſter, to prove the connection of earthquakes with epidemics (an opinion which many writers have adopted); and aſo to ſhew that ſenſible vapours have iſſued from the earth, contaminating the atmoſphere, about theſe periods, or ſometimes without any earthquakes. From theſe ſenſible exhalations an inference is readily drawn of the exiſtence of vapours incognizable by our ſenſes, according to the conjecture of Sydenham. It appears, however, that great peſtilence, even when occurring within a ſhort period of earthquakes, has generally appeared *before* the earthquakes: nor does it occur in the ſeat of the earthquakes. Thus *after* the plague in London, in 1665, ſhocks are ſaid to have been felt *on the continent*. But Mr. Webſter does not conceive this to be any objection to the hypotheſis. He believes "that peſtilence and earthquakes depend on one common cauſe; which excites into action the internal fires." But he ſuppoſes that "the action or fermentation may precede, for months, and even years, the exploſion in earthquakes and volcanoes; and by means of an inſenſible vapour or heat, or electrical diſcharges, the elements of water and air may be eſſentially affected in ſuch a manner as to impair the principle of animal and vegetable life." P. 137.

This hypotheſis, which was held by the ancients, (as Claudian writes,

> "In cœlo nunquam ſpectatum impune cometam,")

has been adopted by Horſtius, Riverius, and echoed by ſeveral other writers on the ſubject of peſtilence; but, like many other ſuppoſitions upon the ſame ſubject, it is altogether gratuitous, and has been received only in the abſence of all poſitive knowledge of the real ſources of peſtilential diſeaſes. The ſame obſervation applies to the ſuppoſed influence of earthquakes, and diſtant volcanic eruptions; more particularly, as the former are allowed to have often followed the effect aſcribed to them, and the countries immediately in the vicinity of volcanoes are admitted to have been not more liable to epidemic diſeaſes than other regions.

Two other points have been generally ſtated as proving the exiſtence of a *peſtilential principle*, which is diffuſed through the atmoſphere at large: one is, that trees and vegetables are affected with mildew, and other diſeaſes; the other, that the animal creation alſo often ſuffers, when peſtilence is committing ravages among mankind. A *rubigo*, or mildew, *i. e.* "a dew impregnated with highly corroſive powers," (ſee Hird on Peſtilence, p. 91.) was anciently deemed one of the cauſes of epidemic diſeaſes. The Romans, appriſed of the pernicious effects of theſe mildews, inſtituted what they denominated *Feſta rubigalia*, and worſhipped an imaginary god, under the name of Robigus. The appropriated ſacrifice was a ſucking whelp; whence Columella,

> "Hinc mala rubigo, virides ne torreat herbas,
> Sanguine lactentis catuli placatur et extis."

Hoffmann mentions ſuch a dew, "ros valde corroſivus," as having infeſted vegetables in 1693-4, whence the cattle died in multitudes. (Tom. i. de Temp. Ann. Inſalub.) And Ramazzini aſcribes an epidemic to ſimilar dews; at which time the vegetables, corn, and fruit became black, being affected with a "lues rubigalis." (Conſtitut. Epidem.) The ſame year was remarkable for the ſcarcity of honey; and moſt creatures that live upon what they extract from vegetables died, or languiſhed. Probably ſimilar occurrences led many of the ancient writers to mention the ſilence of the graſshopper, and the drooping inactivity of the bee and the ſilk-worm, among the preſages of impending peſtilence. As to the ſpots, which are ſaid to have aſſumed various forms, eſpecially thoſe of *cruciculæ*, or little croſſes, and to have appeared ſuddenly on garments, utenſils, &c. as they are recorded chiefly on the authority of monks, whoſe writings are highly tinged with ſuperſtition, they are ſcarcely worthy of ſerious conſideration.

The exiſtence of epidemic diſeaſe among cattle is neceſſarily much connected with the diſeaſed condition of vegetables; and epidemics among cattle ſeem to have moſt commonly occurred after exceſſive humidity. (Webſter.) The calamity among brutes has ſometimes proved the forerunner of peſtilence among mankind; ſometimes its follower; and at other times, they have raged concomitantly: but, in general, their appearance has been remote and unallied. (Hird, loc. cit.)

It is curious, again, and not eaſily explicable on the principle of a peſtilential effluvium, unfriendly to every form of life, pervading the atmoſphere, that, while vegetables droop and are mildewed, the graſshopper is ſilent, the bee and the ſilk-worm are idle, and cattle die, from its influence, ſwarms of inſects and creatures of other ſpecies are ſaid to be among the precurſors and attendants of peſtilence. It is ſurely an abſurdity to contend for the exiſtence of a poiſonous atmoſphere, deſtructive to the life of both animals and vegetables; and at the ſame time to deſcribe the myriads of noxious inſects, frogs, mice, locuſts, ſnails, ſerpents, and other animals, which appear during an epidemic peſtilence! Is one kind of life poſſeſſed by man and the animals uſeful to him, and another by thoſe which are noxious? This contradiction in the hypotheſis appears to be very general among writers. The author, whom we have already often quoted, obſerves, "one thing is very evident, that what I denominate a *peſtilential principle* does, at certain times, pervade not only the element of air, but the water alſo. The proofs of this are abundantly numerous and convincing. In all the great plagues which have afflicted the human race, other animals, as horſes, cattle, ſheep, ſometimes cats, dogs, and fowls, together with the fiſh in rivers and the ocean, and even vegetables, have borne their ſhare in the calamity. The peſtilential principle has extended to every ſpecies of life. The beaſts of the field periſh with deadly epidemics; the fiſh die on the bottom of rivers and the ſea, or become lean and ſickly; while corn is blaſted on the moſt fertile plains, and the fruits in gardens and orchards wither, or fail to arrive at their uſual ſtate of perfection." (Webſter, Hiſt. of Epidemics, vol. ii. p. 153.) And immediately afterwards (p. 166.) we are called upon to "attend to the effects of a peſtilential" (*i. e.* univerſally deleterious) "ſtate of air, and in the *production* of inſects and ſmall animals. This is one of the moſt remarkable ſymptoms of a *ſickly* ſtate of the elements, &c."

It is only againſt ſuch hypotheſes that we have any objection. The fact, that myriads of inſects have ſometimes been produced, about the time when epidemics prevailed, cannot, we apprehend, be queſtioned; although probably many of the accounts tranſmitted to us on this point are much exaggerated. In ſome inſtances, ſuch a profuſion of inſect life may be a reſult of the ſame cauſe with the epidemic, *viz.* extraordinary heat, or heat and moiſture: in others, it may contribute to produce the epidemic, by deſtroying grain and fruits, the food of man; or graſs and herbs, the food of cattle, fowls, and other animals which conſtitute a part of his ſubſiſtence. It proves nothing in reſpect to any occult quality pervading the atmoſphere.

Beſides, the inſtances of the copious generation of inſects and ſmall animals have not been univerſal, but partial: ſome particular ſpecies have been generated in profuſion; and, therefore, the origin of them muſt be aſcribed to ſome partial, and not to a general cauſe. In the plague of Lauſanne, in 1613, according to Diemerbroeck, flies were produced in an incredible abundance; as well as during or preceding that of Holland, in 1635. The approach of the plague at Dantzick, in 1709, is ſaid to have been announced by an immenſe number of ſpiders in the preceding year. The year 1633, which produced a peſtilential fever among the ſettlers at Plymouth, in America, was remarkable for ſwarms of large flies, which filled the woods with their humming ſounds. (Webſter.) We cannot but conſider, therefore, that the ſtatement above quoted of the univerſal failure of animal and vegetable life, on the one hand, or the general diſpoſition in the air to generate noxious animals, on the other, as equally erroneous, inconſiſtent, and abſurd. How the individual ſpecies of inſect or animal is generated, in ſuch caſes, or what connection the production of them may have with the peſtilence, which ſometimes concurs in point of time, we cannot eaſily aſcertain. But where the means of obſervation fail us, gratuitous hypotheſes add nothing to our knowledge.

There are, however, ſeveral circumſtances which are open to our obſervation, which, if they do not abſolutely produce epidemics of the moſt peſtilential kind, certainly contribute to give them birth, and to aggravate them when produced, and are notoriouſly the ſource of epidemics of a leſs deſtructive ſpecies. Of theſe obvious cauſes of the origin or aggravation of epidemic diſeaſes, ſome contribute directly to excite diſeaſe; others to induce, what is ſcarcely leſs neceſſary to their occurrence, a prediſpoſition to them. In fact, the operation of ſome general agent, inducing a prediſpoſition to be affected by contagion, or other exciting cauſe of diſeaſe, would appear to be the principal ſource of the predominance of ſome epidemics. For if the exciting cauſe never, or ſcarcely ever, ceaſes to exiſt, its occaſional activity in inflicting diſeaſe among multitudes can only be aſcribed to the caſual operation of ſome general prediſpoſing cauſe, which renders them temporarily ſuſceptible of its influence. This is particularly exemplified with reſpect to contagious diſeaſes. The contagion of ſmall-pox, meaſles, and ſcarlet-fever perpetually exiſts among us; yet it is only at particular times that theſe diſeaſes attack ſo many individuals, as to be called epidemic. In crowded towns, like this metropolis, the infection of typhous fever is perpetually generated in the cloſe, dirty, and unwholeſome habitations of the poor: yet there has been no epidemic typhus in London for ſeven years paſt. Nay, even the plague itſelf exiſted year after year in this city, without ſpreading generally. It muſt not be imagined that the diſeaſe was accidentally imported juſt at the periods when it raged ſo extenſively, and with ſo much deſtruction. The principal plague-years of the ſeventeenth century were 1603, 1625, 1636, and 1665; in which the number of deaths from the plague, independent of thoſe from other diſeaſes, are reported in the bills of mortality to have been 36,269, 35,417, 10,400, and 68,596, reſpectively. But ſo far was the diſeaſe from being extinct in the intermediate periods, that from the year 1603, when the regiſter begins, till 1667, the bills of mortality exhibit only three years entirely free from the plague. It is obvious, therefore, that the preſence of infectious matter, or other exciting cauſe, is not alone ſufficient to produce an epidemic diſeaſe. Some concurrent circumſtances are likewiſe neceſſary, to give a prediſpoſition to the human body to be readily acted upon by ſuch cauſe. Now, ſome of theſe circumſtances have been well aſcertained, namely, particular ſeaſons, marſhy and other effluvia, a crowded and filthy population, deficient or depraved aliment, certain paſſions of the mind, exhauſtion of the conſtitution by fatigue, &c. We ſhall illuſtrate the operation of each of theſe prediſpoſing cauſes by a few obſervations.

1. *Seaſons.*—The influence of certain ſeaſons, in favouring the propagation of epidemic diſeaſes, has been obſerved and confirmed by all the medical writers on the ſubject, from the days of Hippocrates downwards, and was noticed by the earlieſt poets, even before the time of that great phyſician; eſpecially the influence of the heats of ſummer and autumn, and of the ſultry ſouth winds, which blow at thoſe ſeaſons. In many paſſages of the Iliad, Homer has alluded to theſe cauſes of peſtilential diſeaſes. Thus, in book v.

> "As vapours blown by Auſter's ſultry breath,
> Pregnant with plagues, and ſhedding ſeeds of death,
> Beneath the rage of burning Syrius riſe." Pope, 1058.

And again in book xxii. 37.

> "Not half ſo dreadful riſes to the ſight,
> Through the thick gloom of ſome tempeſtuous night,
> Orion's dog (the year when autumn ſways),
> And o'er the feebler ſtars exerts his rays:
> Terrific glory! for his burning breath
> Taints the red air with fevers, plagues, and death."

In the firſt book, peſtilence is alſo aſcribed to the anger of Apollo, an allegorical expreſſion for the extreme heat of the ſun. (See Pope's verſion, lines 83, and 87.)

Theſe poetic ſtatements accord moſt accurately with the obſervations of Hippocrates, who frequently mentions epidemic fevers as common in the ſummer and autumn, and as prevailing moſt extenſively when wet ſprings with ſoutherly winds were ſucceeded by hot and cloſe ſummers. A remarkable conſtitution of this kind, which continued for two years, is deſcribed in his treatiſe on Epidemics, (De Morbis Vulgaribus, lib. iii.) at which time ardent remitting and intermitting fevers of a bad kind prevailed, attended with fluxes, parotids, and eruptions of a peſtilential nature. The autumn and ſpring were wet, cloſe, and cloudy, without wind, the breezes from the ſouth; and theſe continued during the hot and ſultry ſummer, when the uſual refreſhing Eteſian winds did not blow.

Exceſſive heat of the ſummer, without moiſture, has occaſionally accompanied an epidemic ſeaſon. Thus in the year of Rome 325, there was a moſt grievous famine, occaſioned by a ſevere drought, in all the Roman territory. "Siccitate eo anno plurimum laboratum eſt; nec cœleſtes modo defuerunt aquæ, ſed terra quoque, ingenito humore egens, vix ad perennes ſubfecit amnes;" the cattle thronged in multitudes round the arid fountains, and periſhed with thirſt, diſeaſes followed among the cattle, from which they were propagated by contagion among men ("vulgatique contactu in homines morbi"), the peaſantry firſt ſuffering, then the lower claſſes, and at length the whole city was infected. (Tit. Liv. lib. iv. 30.) In more modern times, great droughts have been accompanied by epidemic diſeaſes, eſpecially in cities ſituated in low and damp countries. In the autumn of 1652, Bartholine informs us that a malignant fever appeared at Copenhagen, after an unuſually hot and dry ſummer. And a ſimilar fever raged at Leyden in the year 1669, as deſcribed by Silvius de la Boe. The ſpring and beginning of ſummer were cold, but the remainder of ſummer, and the autumn, were unuſually hot, with little or no rain, and with a conſtant calm or ſtagnation of the air. (See Pringle on Diſ. of the Army, p. iii. claſs 4.)

But epidemic diſeaſes are ſtill more fatal in thoſe ſeaſons, in the damp countries of the ſouth, where the heats are longer and more intenſe, and much moiſture is combined. In ſome parts of Italy, and in other tracts of the ſame latitude, epidemic fevers have appeared with ſuch alarming ſymptoms, as not only to have been called peſtilential, but confounded with the plague itſelf. In this ſenſe we are to underſtand Celſus, (De Medicina, lib. i. cap. 10. lib. iii. cap. 8.) in the terms *peſtilentia* and *febris peſtilentialis*, which he deſcribes as peculiar to the "grave anni tempus," and the "graves regiones." His meaning is, that this bad fever is the diſeaſe of the latter part of ſummer, and of autumn, when the air is thickeſt and moſt foggy, and that is moſt frequent in low and marſhy countries. Rome was always liable to theſe fevers. Galen calls the *hemitritæa* the epidemic of that city, and ſpeaks of its moiſt air. (De Temperament. lib. ii.)

In fact the chief malignancy of the worſt epidemic diſeaſes, and of the plague itſelf, has always been felt in the ſummer and autumn; as the hiſtories of that diſeaſe in all the large towns in Europe will teſtify. Diemerbroeck has juſtly obſerved, that when the plague has been excited out of its proper ſeaſon, it has not ſpread: and Dr. Ruſſell tells us, that in the winter time, when infected perſons have come to places about Aleppo, ſome of whom have died in the families where they lodged, the diſtemper by ſuch means was not propagated. In the four great plagues of London, during the ſeventeenth century, the mortality invariably increaſed, as the ſeaſon advanced, reaching its acmè in Auguſt and September, and thenceforth gradually declining. (See the Bills of Mortality.—See alſo Dr. Heberden, jun. on the Increaſe and Decreaſe of Diſeaſes, 1801.). Thus in the laſt plague in London, in the year 1665, the mortality of the reſpective months was as follows; in the ſpring very few perſons had died of the plague, in June 590 perſons died of it, in July, 4,129, in Auguſt, 19,046, in September, 26,230, in October, 14,372, in November, 3,349, and in December a few hundreds. (See PLAGUE.) The progreſs, in the other three inſtances, was exactly ſimilar.

Again, the regular decreaſe of peſtilential diſeaſes, with the declining ſummer, equally demonſtrates the neceſſity of the preſence of the hot ſeaſon for their propagation; which may operate either by rendering the contagion more virulent, by producing certain pernicious effluvia from the earth in moiſt places, or by inducing a prediſpoſition in the human body to receive the influence of thoſe exciting cauſes. At Grand Cairo putrid and peſtilential fevers prevailed annually in March, April, and May, which the ſoutherly winds make the hotteſt months in that country; but they ceaſed at the overflowing of the Nile, when the cold winds ſet in. (Proſper. Alpin. de Med. Egypt, lib. i. cap. 14. Mead on the Plague, p. 30.) And "at Smyrna the annual plague conſtantly ceaſes about the 24th of July, by the *dry and cold weather* they always have at that time." (Mead, p. 56.) Indeed, when this change of ſeaſon takes place, while every place abounds, it muſt be preſumed, with the contagion, yet it ceaſes to be detrimental. Proſper Alpinus remarks, that when this change of ſeaſon comes, in the month of June, even the clothes imbued with the moſt peſtiferous contagion then infect no one. "Sed quod valde mirabile creditur, omnia ſupellectilia peſtifero contagio infecta tunc nullum contagii effectum in eam gentem edunt."—And this inertneſs of the contagion in the moſt infected places, on the approach of winter, was moſt remarkable in the laſt plague of London. "Many who made moſt haſte in retiring," ſays Dr. Hodges, "made the moſt to return, and came into the city without fear: inſomuch, that in December they crowded back as thick as they fled: the houſes, which were before full of the dead, were now again inhabited by the living; the ſhops, which had been moſt part of the year ſhut up, were again opened, and the people again cheerfully went about their wonted affairs of trade and employ: and even what is almoſt beyond belief, thoſe citizens, who before were afraid even of their friends and relations, would, without fear, venture into the houſes and rooms where infected perſons had but a little before breathed their laſt: nay, ſuch comforts did inſpire the languiſhing people, and ſuch confidence, that many went into the beds, where perſons had died, before they were even cold, or cleanſed from the ſtench of the diſeaſed." (Loimologia, or Hiſt. Acc. of the Plague in 1665, p. 27.) In the ſame way we read, that when the plague was in Italy, the Neapolitans uſed no artifice to purify either their goods or houſes; yet the diſeaſe ceaſed among them as entirely as in the beſt regulated towns. (Heberden, loc. cit.)

Theſe facts amply prove the extenſive influence of certain ſeaſons, in favouring and interrupting the progreſs of the moſt peſtilential epidemics; and that not in conſequence of any occult, but of certain ſenſible and obvious conditions of the weather. The ſame circumſtances of the ſeaſons modify the propagation and diminution of the minor epidemics, ſuch as dyſentery, remittent and intermittent fevers, &c. and even the ſmall-pox. Of the former of theſe, we ſhall more properly ſpeak under the ſecond head of cauſes; namely,

2. *Marſhy and other Effluvia.*—Galen aſſigns two cauſes for peſtilential fevers; the firſt of which is great heat of the weather, and the ſecond, which he conſiders as moſt frequent, a corrupted ſtate of the air, ariſing either from a multitude of dead bodies left unburnt, as after a battle, or from the evaporation of corrupted lakes and marſhes. (De Febr. Diff. lib. i. cap. 4.) Other authors of antiquity have noticed the coincidence of epidemic fevers with marſhy ſituations. Thus Diodorus, the hiſtorian, has recorded the occurrence of a peſtilential diſeaſe among the Carthaginians at the ſiege of Syracuſe, which he attributes to the combination of the following circumſtances; the multitude of people confined within a narrow compaſs, the ſituation of the camp in a low and wet ground, and the ſcorching heats in the middle of the day, ſucceeded by cold and damp air from the marſhes in the night. (Bibl. Hiſt. lib. xiv. cap. 70.) In more modern times the origin of epidemic diſeaſes from marſh effluvia had been very generally obſerved. Fracaſtorius aſcribes a malignant epidemic fever, in Italy, in the ſixteenth century, to an extraordinary inundation of the Po, which, happening in the ſpring, left marſhes, and thoſe corrupting infected the air through the ſummer. Foreſtus remarks, that, from the putrefaction of the water only, the city of Delft, where he practiſed, was ſcarcely ten years free from the plague or ſome peſtilential diſtemper. (Obſervat. lib. vi.)

The effects of marſh or putrid effluvia in giving riſe to epidemic diſeaſes have, indeed, been evinced in moſt of the large cities, and ſtill more obviouſly in the camps of modern times. Sir John Pringle, ſpeaking of the hot weather, during one of the campaigns in the Netherlands, in 1748, obſerves, that though the heats were great, yet they were the cauſe of little ſickneſs, till the troops were cantoned in the marſhes, where a conſiderable degree of putrefaction and moiſture being joined, ardent, remitting, and intermitting fevers, and fluxes became general. It is remarkable that theſe pernicious exhalations do not riſe high, nor ſpread far from their ſource, at leaſt without ſuch dilution as diminiſhes their deleterious qualities. Dr. J. Hunter has affirmed, that in the barracks at Spaniſh Town, in Jamaica, (which conſiſted of two floors, the firſt upon the ground, the ſecond over the firſt,) the difference in health of the men on the two floors was ſo great as to engage the attention of the aſſembly of the iſland, and upon inveſtigation it appeared that three were taken ill on the ground floor for one on the other. Even at a few hundred feet above the level of the marſhes, the ſituations are extremely healthy. (Obſerv. on the Diſ. of the Army in Jamaica, note B. p. 268, 3d edit.) The air of a marſh or of a foul camp, the ſame author obſerves, may deſtroy an army almoſt as ſoon as the true plague. But the remedies in ſuch caſes are obvious, and conſiſt in getting at a proper diſtance from the noxious exhalations, or removing the cauſes of them. "A very ſmall ſpace frequently includes the limits of healthy and unhealthy ground." It is not now neceſſary to ſtate that agues, or intermittents, originate ſolely from the effluvia of marſhes.

Another ſpecies of effluvia, which is the ſource of epidemic diſeaſes in camps and in towns, when ill conſtructed and neglected, ariſes from ground contaminated with human and other excrements, the remains of victuals, the water uſed in cookery, for waſhing, the foul ſtraw rotting in tents, &c. Whenever a camp remains long on the ſame ground, eſpecially in hot and moiſt weather, fluxes, and intermitting and remitting fevers, ſeldom fail to become epidemic, unleſs great precautions are uſed to bury all excrementitious matter, and proper receptacles and drains under ground are prepared for the urine, water of cookery, &c. (See Dr. Hunter, loc. cit. p. 285.) In this caſe, however, as in that of marſh effluvia, the diſeaſes produced will diſappear, by moving the camp a few hundred yards from the foul ground.

Theſe facts throw great light on the epidemics of large cities, which were formerly ſo frequent and fatal. A large town may be conſidered as an extenſive camp, but deſtitute of the means of changing its ſituation, and, conſequently, liable to be infeſted with the ſame diſeaſes as are endemic and epidemic in camps, unleſs the precautions juſt alluded to, for the purpoſe of removing the ſources of the peſtilential effluvia, be fully adopted. And we find, accordingly, that during and previous to the 17th century, (and even later, in ſome countries,) the large towns were almoſt conſtantly infeſted, in the ſummer and autumnal months, with the plague, malignant, intermittent, and remittent fevers, and dyſentery; the ſame diſorders to which camps are liable. This was the condition of London during the period ſpecified. We have already remarked, that the plague was ſeldom abſent from the beginning of the 17th century to the year 1669, and that four dreadful viſitations of that calamity occurred within the ſame ſpace of time. Of the extent to which intermittent and remittent fevers prevailed, in this metropolis, we have alſo ample evidence. Dr. Short remarks, that early in the century, *viz.* between 1629 and 1636, "one of 40 of the whole that died of fevers, died of agues;" whereas, "now (1750) ſcarce *one* of 1100 that die of fevers die of this diſeaſe." (New Obſ. Nat. Moral, &c. on Bills of Mortality, 1750, p. 208.) Burnet, in his "Hiſtory of the Reformation," ſays, that in the laſt year of queen Mary's reign "intermitting fevers were ſo univerſal and contagious, that they raged like a plague." Both Sydenham and Morton have left us abundant evidence of the frequent epidemic prevalence of agues, as well as of remitting fevers, which laſt Morton affirms to have been extremely deſtructive for ſeveral years before the great plague, *viz.* from the year 1658 to 1664. He ſtates that Oliver Cromwell died of this fever in 1658; and that his own father, himſelf an experienced phyſician, alſo died of it; when his whole family, the writer included, were infected. (Morton, Pyretologia, App. ad Exercit. ii.) Even ſo late as from 1720 to 1729, according to Dr. Short, "they (intermittents) and remittents afflicted the whole nation grievouſly."

Sometimes together, and ſometimes alternating with thoſe autumnal fevers, the dyſentery was a frequent epidemic in London, in the times to which we allude, and was often attended with great fatality. For five and twenty years ſucceſſively, from 1667 to 1692, the bills of mortality ſhew the ſum of deaths under the titles of "bloody flux," and "griping in the guts," which muſt both be conſidered as dyſentery, to have amounted every year to above 2000. During the laſt century, the diſeaſe has gradually declined, (Dr. Heberden on Increaſe and Decreaſe of Diff. Diſeaſes, p. 34.) and the other fatal epidemics, juſt mentioned, have quite diſappeared. See Annual Medical Regiſter for 1808, vol. i. where the changes of diſeaſe in London are diſcuſſed at length.

We cannot doubt, that the preſent comparative healthineſs, and eſpecially the great freedom from all epidemics (the contagions of ſmall-pox, ſcarlet fever, and meaſles excepted) which this metropolis now enjoys, is to be aſcribed altogether to the meaſures, by which the ſources of the effluvia, which excite them, have been removed, and to the general habits of cleanlineſs and ventilation which are at preſent obſerved by the people. Theſe ſalutary meaſures are principally the conſtruction of privies, drains, and common ſewers; a hard and regular pavement, with a proper level for carrying off the humidity, and well cleanſed by ſcavengers; an abundant ſupply of water to every part of the town, &c.

In all theſe points, the condition of London, like that of moſt other large cities in Europe, during the 17th century, was extremely defective. In the preceding centuries its condition muſt have been ſtill more incommodious and filthy, ſo that few years elapſed without the occurrence of a conſiderable peſtilence. We have not room, in this place, to enter more at large into a deſcription of its circumſtances; but muſt content ourſelves with referring to the work of Dr. Heberden, jun. juſt quoted, where an abundant collection of evidence, as to the connection of thoſe epidemics with filth and negligence in the economy of this and of other large towns, will be found. (See alſo the Ann. Med. Regiſter for 1808. Maitland's and Nourthouck's Hiſtory of London.) See Plague.

It is extremely gratifying, both in a phyſical and moral point of view, to obſerve that the ſame means which contribute to our perſonal comforts, and to elevate us above the ſavage, *viz.* the progreſs of civilization and refinement, have led to baniſh the moſt loathſome and fatal diſtempers, to prolong life, and to diminiſh the prevalence and fatality of other diſeaſes of leſs fatality. "While the metropolis has extended itſelf in all directions, and multiplied its inhabitants to an enormous amount, *i.e.* while the apparent cauſes of its unhealthineſs have been augmented, it has actually become more favourable to health. In the year 1697, for example, the total mortality of London was 20,970; whereas, the total mortality of 1797 amounted only to 17,014: and when we take into conſideration the great increaſe of the population of the out-pariſhes at the latter period, the *comparative* healthineſs of London will appear in very ſtrong colours." Ann. Med. Regiſter, p. 321.

Sometimes the air of a particular diſtrict ſeems to have been impregnated with effluvia from putrefying animal and vegetable matter, which has occaſioned an epidemic in that neighbourhood. Foreſtus has mentioned the putrefaction of a large fiſh, of the whale kind, which was left by the tide, and died, on the coaſt of Holland, and, during its putrefaction, infected the country with a horrid ſtench, in conſequence of which a fatal epidemic fever broke out in the diſtrict of Egmont. (Obſ. lib. vi. 9. tom. i.) The ſame author informs us of a peſtilential fever, which raged at Venice in his time, and was produced by the corruption of a ſmall kind of fiſh in that part of the Adriatic. (Ibid.) Inſtances are alſo on record of epidemic fevers occaſioned by the effluvia of putrid cabbages, as well as of plants in marſhes. (Rogers on Epidem. p. 41.) Theſe ſources of epidemics, however, are rare, and can ſeldom occur under a well regulated police.

3. *A crowded Population.*—From the earlieſt periods of time, of which we have any record, peſtilential diſeaſes were known to be the effect of crowded population, and to rage peculiarly in cities, forts, and other confined places. In the ſacred writings peſtilence is every where mentioned as the peculiar ſcourge of *cities*. "The ſword is *without*," ſays the prophet Ezekiel, chap. vii., "and the peſtilence and famine *within*; he that is in the field ſhall die with the ſword; and he that is in the *city*, famine and peſtilence ſhall devour him." And again, chap. xxxiii., it is ſaid, "they that be in the *forts* and the caves ſhall die of the peſtilence." The city of Rome was ſubject to the moſt fatal epidemics from a very early period of its hiſtory: Athens ſuffered alſo extremely; and in modern Europe the great cities have been the common ſeats of plagues, from Conſtantinople to Moſcow, and from Cadiz and Marſeilles, to Copenhagen and Dantzic. (See an enumeration of the cities infected with the plague, and the dates of its occurrence, by Dr. Heberden, *loc. cit.* p. 81, *et ſeq.*) The ſame obſervation applies to the cities of Aſia and Africa; to Aleppo, Cairo, &c. &c., as well as to thoſe of America.

We have already ſtated, that the prevalence of epidemic and peſtilential diſeaſes in this metropolis was obviouſly connected with the exiſtence of filth of every ſpecies, and that their gradual diſappearance has been coeval with the improvements of the city, and the removal of theſe nuiſances. The ſame fact is obſervable in all the cities of Europe: and thoſe which, from natural or political cauſes, have been backward in adopting the improvements of modern times, have more lately exhibited the ſame effects of their negligence. The plague appeared at Copenhagen in 1764; and at Moſcow ſo late as the year 1771. It is farther obſervable, that peſtilential diſeaſes generally appear firſt in the moſt crowded and uncleanly parts of towns, and rage moſt ſeverely in the moſt crowded and dirty habitations, *i. e.* among the poor. The plague of 1665, in London, is ſaid to have been by many perſons called "the poor's plague." Thoſe of 1626 and 1636 broke out at Whitechapel, a part of the town which abounded with poor, and with ſlaughter-houſes: and that of 1665 is ſaid to have broke out firſt at St. Giles's; and there, Dr. Heberden remarks, it would probably break out again, if ever we ſhould ſuffer ſuch another calamity.

For it muſt be obſerved, that a crowded and uncleanly population contributes, in a double manner, to the origin and propagation of epidemic and peſtilential diſeaſes. It not only occaſions the accumulation of every ſpecies of filth externally, from which effluvia ariſe to contaminate the atmoſphere, in hot and moiſt ſeaſons, thus producing all the diſeaſes of camps; but it produces another ſpecies of effluvia, internally, in the habitations of men; *viz.* from the bodies of the ſick, and even of the healthy, which at once generate malignant fevers, and aggravate thoſe which ariſe from the other ſources. (See CONTAGION.) So that under the circumſtance of the combination of theſe cauſes, namely, when the heat and moiſture of autumn generate the effluvia from external filth, and contagion is ſuperadded from the accumulation of the corporeal effluvia, from the want of internal cleanlineſs and ventilation, diſeaſes of an epidemic nature are readily excited, and are propagated extenſively and fatally. Hence, before the value of theſe internal cautions was underſtood, malignant fevers ſo frequently occurred in hoſpitals and gaols, that they obtained the appellation of hoſpital-fever and gaol-fever. Indeed we are told that, ſo late as the latter end of the 17th century, in the gaol of Newgate, a contagious fever uſed to break out annually, in hot weather; and that the ſame was true of moſt gaols in Europe; (The City Remembrancer, quoted by Dr. Heberden) and ſeveral facts on record, prove, how readily any acute diſeaſe is thus propagated by contagion, under theſe circumſtances of crowded and filthy habitations; although originally, and in cleanly and airy apartments, it was incapable of ſpreading from one individual to another. Thus ſir John Pringle obſerved, that, "in autumn 1757, ſeveral ſoldiers were brought into the hoſpital at Portſmouth, with a diſorder compounded of the autumnal and gaol-fever; for when theſe men, upon being ſeized with the common fever of the ſeaſon, were confined to the holds of the crowded tranſports, their diſtemper aſſumed that form. (Diſ. of the Army.) So Dr. Lind has ſtated, that, upon admitting into an hoſpital one perſon with a flux, ſeveral other patients in the ſame ward have had this ſymptom added to their other complaints. (Lind on Fever and Infection.) And Dr. Blane has obſerved generally, that, ſuppoſing a ſhip's company be prediſpoſed to acute diſtempers, and one man or more ill of a dyſentery be brought on board, this will become the prevailing diſeaſe. (On the Diſeaſes of Seamen.)

Theſe facts, which evince the facility with which any acute diſeaſe, or its leading ſymptom, is communicated from individual to individual, in a cloſe and crowded apartment, when extreme cleanlineſs and ventilation are not attended to, will ſerve to explain ſeveral apparent anomalies in the hiſtory of ſeveral diſeaſes, which have been ſtated as the reſult of ſome myſterious epidemic principle in the atmoſphere. We allude to the occaſional ſpreading of particular maladies in hoſpitals, in a ſort of epidemic way; ſuch as the appearance of eryſipelas, connected with all ſlight injuries of the ſcalp, or other ſuperficial parts, as related by ſir William Blizard, of the London hoſpital, and as occurred in the ſurgical ward of the Royal Infirmary at Edinburgh, many years ago; the diſpoſition to inflammation and abſceſs about the perineum and neighbouring parts, mentioned by the ſame writer, &c. (See a Paper "On ſome epidemical Effects," Med. Facts and Obſ. vol. ii. 1792.) Such occurrences, we believe, are rare in proportion to the degree of cleanlineſs in thoſe receptacles of the ſick. We have been aſſured that the occurrences of this nature at Edinburgh have ceaſed, ſince a more rigid ventilation and purification have been adopted in the Royal Infirmary.

4. *Deficient and Depraved Aliment.*—The obvious cauſes of epidemic diſeaſes, already mentioned, may operate both as exciting and as prediſpoſing cauſes; but that to which we now direct our attention, perhaps, chiefly acts in inducing a debilitated and half-morbid condition of the body, which renders it liable to be affected by thoſe exciting cauſes. Certain it is that famine and peſtilence have been obſerved to go together, ſince the earlieſt ages of the world; and are conſtantly mentioned in combination, in the ſacred writings; to which war is frequently added. Dearth is almoſt neceſſarily a part of the deſolation of war; which, therefore, contributes to the production of peſtilence indirectly by producing dearth. Ὁ λοιμὸς μετὰ λιμον, "the plague after famine," was an old Greek adage. Where articles of food are extremely ſcarce, they are often alſo corrupted, and may thus contribute to reduce the human conſtitution to a ſtate prediſpoſed to diſeaſe. Foreſtus imputes the plague at Delft, in the year 1557, to the eating of mouldy grain, which had been long kept up by the merchants in a time of ſcarcity. (*Loc. cit.*) And ſir J. Pringle ſays, he had heard it obſerved, that in this iſland the dyſentery is frequent among the common people, in thoſe parts where they

live moſtly on grain, when the preceding crop has been damaged in a rainy ſeaſon, or kept in damp granaries. (*Loc. cit.* cap. vii. p. iii.) In ancient times the corruption, as well as ſcarcity of food, was aſſigned as the cauſe of peſtilence; as by Cæſar himſelf when beſieging Marſeilles, (De Bello Civili, lib. ii. 20.) "Panico enim vetere, atque hordeo corrupto, omnes (*ſcil.* Maſſilienſes) alebantur; quod ad hujuſmodi caſus antiquitus paratum, in publicum contulerant." When we advert to the fatal epidemic diſeaſe, termed Feu ſacrè, Mal des ardens, &c. by the French, and known to originate from *ergoted* rye, uſed as food, we ſhall not heſitate to aſcribe conſiderable effects to the ſort of food juſt mentioned. (See Philoſ. Tranſact. vol. lv. p. 110, and Mem. de la Soc. Royale de Medecine, for 1776.) Dr. Willan has obſerved, that the Morbus Hungaricus, deſcribed by Sennertus, "and ſome other diſeaſes reputed peſtilential, might be added to the liſt of epidemics, occaſioned by the *ergot;* or by a ſimilar degeneration in other grain. The ſweating-ſickneſs, which occurred more than once in England, at the beginning of the ſixteenth century, was perhaps owing to ſome diſeaſe or depravation in wheat, &c." (On Cutaneous Diſeaſes, part iv. p. 499.) It may be added, that the only epidemic occurrence of contagious fever in London for ſeveral years back, occurred after the exceſſively wet autumn of 1799, when corn was exceedingly damaged, and a conſiderable ſcarcity enſued.

5. *Exhauſtion by Fatigue, &c.*—Beſides the debility of conſtitution, and conſequent prediſpoſition to diſeaſe, induced by imperfect nouriſhment, during a famine, the exhauſtion produced by exceſſive corporeal exertions, loſs of ſleep, and the depreſſing paſſions, probably contributes in no ſmall degree to prediſpoſe the body to diſeaſes. Thus epidemic fevers have been obſerved to ariſe after great battles. Dr. Gottwald traced the origin of the plague at Dantzick to Pinozow, ſoon after the battle of the Swedes and Saxons, in 1702. (Ingram, Hiſt. of Plagues, p. 86.) To the ſame cauſe, perhaps, we may impute the contagious fever, which raged among the troops of the late ſir John Moore, on their return from the haraſſing campaign in Spain. (1809.) Van Swieten obſerves, that "ſtrong paſſions of the mind, particularly terror, augment the efficacy of infection, as all writers on the plague unanimouſly allow," and that the ſame paſſion contributes to render the diſeaſe more fatal. If this be correct, the extenſive operation of fear in beſieged towns, and countries which are the ſeat of war, muſt produce conſiderable influence; and it cannot be doubted, that the general panic, which rapidly ſpreads among the inhabitants of a town, where the plague is diſcovered to exiſt, contributes materially to its propagation.

On reviewing the facts above ſtated, it is obvious that the ſources of epidemic and peſtilential diſeaſes have been often traced to manifeſt circumſtances, in combination with one or more of which they have generally been obſerved to occur: and more eſpecially that the heats of ſummer and autumn appear to be abſolutely neceſſary to the propagation of a general peſtilence. The obſervation of Celſus, in regard to the ſalubrity of the different ſeaſons, has been confirmed by thoſe who have practiſed in warm climates, (Cleghorn on diſeaſes of Minorca) by the phyſicians of camps, (Pringle, *loc. cit.* part ii. chap. i.) and by the condition of this country in the time of Sydenham. "Saluberrimum ver eſt; proxime deinde ab hoc, hiems; perículoſior æſtas; *autumnus longe periculoſiſſimus.*" (Celſi De Med. lib. ii. cap. i.) But the experience of the laſt century, during which this order of the ſeaſons, in point of ſalubrity, has been almoſt reverſed, (for we now find July and Auguſt the moſt healthy months of the year, and February and March the moſt productive of diſeaſe,) has thrown conſiderable light even on the occult principle, the τὸ θεῖον, of the epidemic atmoſphere. It has ſhewn us, what Sydenham could not have anticipated, and what to him indeed muſt have been incredible, that, while the ſeaſons continue to occur, with their former viciſſitudes, and while the bowels of the earth (for aught that we know) continue to ſend forth their vapours as uſual, yet thoſe fatal peſtilential *conſtitutions* of the air no longer appear; the plague has not been ſeen, ſince the rebuilding of the city (1667); intermittents no longer infeſt the metropolis, and the autumnal remittents are alike almoſt unknown; eſpecially ſince the covering of Fleet ditch, and the other improvements, made in 1766; and the dyſentery, or bloody flux, now ſcarcely adds twenty to the annual bills of mortality! This occult principle, then, this epidemical *ſomewhat*, it muſt be inferred, neither owed its origin to the atmoſphere, nor to the bowels of the earth, nor to the eruptions of Ætna, nor to the approach of comets. For the former of theſe are, doubtleſs, unchanged; and the latter have continued to occur at intervals as uſual.

To what, then, are we to attribute the origin of thoſe *epidemic conſtitutions*, as they have been called, of particular years, in which certain diſeaſes extenſively prevail? We have not, perhaps, a ſufficiency of facts to enable us to deduce a decided concluſion; but the following inference ſeems to approximate to the truth, and to ſpring out of the facts already detailed.

The experience of camps, eſpecially in moiſt ſeaſons, teaches us how readily epidemical diſeaſes are produced, from the contamination of the lower portion of the atmoſphere with the effluvia of foul ground, and alſo how confined and local that contamination is, ſince a ſmall elevation, or a removal to the diſtance of a few hundred yards, from the ſource of the effluvia, is ſufficient to enable us to eſcape their noxious effects. The experience of gaols and hoſpitals, and other crowded and uncleanly habitations, has alſo demonſtrated the facility with which human effluvia, accumulated about the ſick, become contagious to thoſe in their immediate vicinity; and alſo how readily, in this prediſpoſed and contagious ſtate, any acute diſeaſe, *accidentally* introduced, is carried from individual to individual, ſo as to become the prevalent or epidemic diſeaſe. Now, London, and all other crowded cities in the 17th century, combined within themſelves both theſe peculiarities of condition, belonging as well to camps as to gaols and hoſpitals. The atmoſphere was contaminated with the local effluvia, which rendered it peſtilential externally; and, within the dwellings, eſpecially in the poorer parts of the town, infectious atmoſphere was produced, and thus whatever diſeaſe was generated, was propagated readily, and gave a character to the particular *conſtitution* of the epidemic ſeaſon. How variouſly the epidemics muſt be modified, according to the various degrees and combination of the exciting and pre-diſpoſing cauſes, muſt be obvious on reflection. When the bodies of the people happen to be pre-diſpoſed to diſeaſe by want of food, or actually diſordered by corrupted food, when the accumulation of filth, or the increaſe of marſhy ground from rains or inundations, ſend forth miaſmata in a moſt abundant and concentrated form, in conſequence of a peculiar autumnal ſeaſon, the moſt extenſive epidemic diſeaſes may be expected to ariſe. And we believe, that under ſuch a combination of obvious circumſtances, peſtilence never fails to appear.

On the other hand, although a large city cannot, like a camp, be removed from the ſource of the peſtilential effluvia, which it generates, yet induſtry may remove the ſource of theſe effluvia from it. And it appears to be a perfect confirmation of the preceding concluſions, that, as this removal has been accompliſhed in London, (for example,) as the arts of peace and civilization have advanced, and wealth has introduced the diſpoſition and the power to multiply perſonal comforts and conveniences; and as habits of cleanlineſs and ventilation have been generaly diffuſed; in the ſame proportion, and with equal ſteps, the improvement of the general health, the abſolute diſappearance of the plague and the other epidemics, and the increaſe of longevity, are to be remarked. Hence it is only within the laſt few years, that the deaths have fallen ſhort of the number of births within the bills of mortality of London.

We cannot, from our preſent knowledge of facts, however, account for all thoſe modifications of diſeaſes, nominally the ſame, which are obſerved to prevail at different ſeaſons, and which require different modifications of the treatment. It can only be ſtated as highly probable, that whether the epidemic diſeaſes originate from contagion, or human effluvia, or from the effluvia of foul ground, their degrees of violence may depend on the degrees of concentration of thoſe effluvia; and the contagion of a mild or ſevere diſeaſe may tend to propagate more particularly a diſeaſe of ſimilar character. We have already ſeen that peculiar ſymptoms, ſuperadded to an acute diſeaſe, as affections of the lungs or of the bowels with general fever, are readily propagated along with that fever, and have modified both its character and the requiſite treatment.

It has been juſtly obſerved, that "in military phyſic," (and the obſervation applies to epidemic diſeaſes in general,) "the great improvements to be made are not ſo much in the cure as in the prevention of diſeaſes, which depends altogether upon the knowledge of their cauſes." (Dr. John Hunter, *loc. cit.* p. 281.) Now one of the moſt important circumſtances to aſcertain, during the prevalence of an epidemic is, whether it ariſes from contagion, that is, from the influence of effluvia from the bodies of the diſeaſed, or from the contamination of the air by the effluvia of foul ground, &c. For "if a diſeaſe ariſe from contagion," as the author juſt quoted remarks, "there are ſure remedies againſt it, which are ſo well aſcertained, that while the plague, the moſt contagious and the moſt fatal of all diſeaſes, commits its greateſt ravages in large cities, individuals remain in the midſt of them in perfect ſecurity, truſting to a careful ſecluſion under proper regulations. (See CONTAGION.) Again, if diſeaſe ariſe from the air contaminated by the foul ground of a camp, or the exhalations of a marſh, it can only be avoided by a change of ſituation, or by taking care not to come within the ſphere of activity of ſuch noxious cauſes." Or in a large town, it may be added, by a ſtrict enforcement of public and private cleanlineſs. But it is often extremely difficult to decide upon this point; a generally operating cauſe affects ſuch a number of individuals about the ſame time, in the ſame ſituation, that they may ſeem to be infected by each other. So that, in fact, it has been diſputed whether the plague itſelf be a contagious diſeaſe; and in regard to the dreadful epidemics of America, medical obſervers are by no means agreed as to their contagious origin. The contagion of the plague will be diſcuſſed hereafter. In the mean time we ſhall ſtate ſome obſervations which may help to guide our deciſion in ſuch caſes.

By a contagious diſeaſe, is to be underſtood a malady in the courſe of which a poiſon is generated in the body of the ſick, which produces in others a ſimilar diſeaſe. The poiſon in ſome diſeaſes, as the ſmall-pox and chicken-pox, is ſufficiently apparent; and the other diſeaſes, which alſo ariſe from ſpecific contagion, and occur but once during life, as meaſles, ſcarlet fever, hooping-cough, &c. are well known. In others, again, as in typhus and the plague, it almoſt eludes our ſenſes, and is only active when concentrated or accumulated, or cloſe to the body of the ſick. Now theſe contagious diſeaſes equally affect all ages and deſcriptions, who ſuffer expoſure to their cauſe: wherever they prevail, the old inhabitants of a country ſuffer as much as thoſe that have lately arrrived. But this is never the caſe in the yellow fever, remittent fever, or even intermittent fever, which ariſe from external miaſmata; for ſuch as are ſeaſoned to the country or climate ſuffer infinitely leſs than new-comers. Again, diſeaſes proceeding from ſuch a cauſe, generally diffuſed, and operating upon all, do moſt conſtantly recur in the ſame perſons as long as they remain expoſed to the original cauſe; thus in camps and marſhy ſituations, the ſick are conſtantly relapſing in remittents and intermittents, till they change their ſituation. Dr. Hunter particularly obſerves, that the mortality among ſoldiers in the Weſt-Indies is, in a great meaſure, owing to theſe repeated attacks. But what the ſame writer conſiders as the *experimentum crucis*, to prove the non-exiſtence of contagion, is, when the ſick leave their uſual reſidence, and go to other places which are healthy, without ſpreading the diſeaſe. This conſtantly happens in the remittent fevers of the Weſt-Indies; for the good effects of changing the air of the towns for that of the mountains is ſo well known, that it is very generally practiſed; but certainly without the ſlighteſt ſuſpicion of any miſchief ariſing from any contagion carried by the ſick. If we try by this rule the fever epidemic in Philadelphia in 1793, we ſhall not pronounce it to be contagious. One obſervation more may be added: when diſeaſe ariſes from a cauſe generally diffuſed, ſeparation, which in contagious diſeaſes is commonly effectual, is here of no avail. Thus, ſhips of war have gone into a harbour in the Weſt-Indies, and have had no intercourſe with the people on ſhore, or with the crews of other ſhips, and yet in a few days the men have been ſeized with the prevailing fever in great numbers. (Hunter, ibid.)

With reſpect to the laſt argument but one, indeed, the inference is not perfectly concluſive; for malignant typhoid fevers, (and the plague, which is probably but an extreme degree of the ſame fever,) although they produce a contagion that is active and virulent in a confined and cloſe atmoſphere, nevertheleſs become much leſs contagious, in a clear and open air; ſo that we ſhould expect that, on a removal of the ſick to the country, the diſeaſe would aſſume a leſs virulent form. In the plague at Moſcow in 1771, we are told by Dr. Mertens, that the patients, who were conveyed to the neighbouring villages, communicated the diſeaſe to the inhabitants of thoſe places; which they would the more readily do, as probably their cleanlineſs was not ſuperior to that of Moſcow itſelf.

The ſpecific contagions, as they have been called, as ſmall-pox, meaſles, and ſcarlet-fever, which occur but once in the courſe of life, and chiefly attack children, become epidemic generally at pretty regular periods, in large towns. This may be principally explained, perhaps, by the circumſtance of the neceſſary interval requiſite for the production of ſubjects, who have not undergone theſe diſeaſes.

On the whole, however, although the progreſs of refinement in the comforts of human life, during the laſt century, have thrown much light on the nature and origin of epidemic conſtitutions, in different years; it muſt be allowed, nevertheleſs, that much farther obſervation of facts will be requiſite, in order to illuſtrate the ſubject completely.

EPIDENDRA, from επι, *upon*, and δενδρον, *tree*, in *Natural Hiſtory*, a word uſed by ſir Hans Sloane, and ſome other authors, to expreſs thoſe plants which grow upon others, ſuch as the miſletoe, which grows upon the apple-trees, &c. Theſe are more commonly diſtinguiſhed by the name of paraſitical plants. See Dodder.

EPIDENDRUM, in *Botany*, ſo named by Hermann, Linnæus, and others, from επι, *upon*, and δενδρον, *a tree*, becauſe moſt of the ſpecies, if not all, grow paraſitically on the trunks or branches of trees. Linn. Gen. 464. Schreb. 606. Willd. Sp. Pl. v. 4. 114. Mart. Mill. Dict. v. 2. Juſſ. 66. Swartz. Act. Holm. 1800. p. 240. Tracts on Botany, 182. Schrad. Journal, 1799. 209. t. 1. Orchid. in Schr. Neues Journ. v. 1. 79. Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juſſ.

Gen. Ch. reformed. *Cal.* three-leaved. *Cor.* Petals two, nearly equal to the calyx-leaves, ſpreading; nectary a lip, turbinate and tubular at the baſe, connected with the ſtyle, deſtitute of a ſpur, its termination dilated, aſcending, ſpreading, either undivided or lobed. *Stam.* Anther an hemiſpherical, deciduous, terminal lid, of two or four cells; maſſes of pollen ſtalked, in pairs. *Piſt.* Germen inferior, oblong or obovate, erect, furrowed; ſtyle ſemi-cylindrical, often gibbous, concave in front; ſtigma either concave or convex, in the fore-part of the ſtyle near the top. *Peric.* Capſule oblong or obovate, with three or ſix ribs, with one cell and three valves, opening by clefts between the ribs. *Seeds* numerous, minute, each clothed with a chaffy tunic, inſerted into the downy internal ridges of the valves.

Eſſ. Ch. reformed. Calyx-leaves ſpreading. Lip tubular at the baſe, attached to the fore-part of the ſtyle, deſtitute of a ſpur. Anther a terminal lid, deciduous.

The original genus of *Epidendrum* in Linnæus, whoſe eſſential character is "Nectary turbinate, oblique, reflexed," comprehends many ſpecies which do not anſwer to that character, and which have, indeed, in ſeveral inſtances, been referred to this genus without a ſufficient knowledge of their flowers. Hence profeſſor Swartz has chiefly derived his genera of *Cymbidium*, *Dendrobium*, (ſee thoſe articles,) *Oncidium*, *Aërides*, and *Vanilla*, ſo that his *Epidendrum*, whoſe characters we have given above, is become a much ſmaller, as well as a more intelligible genus, though perhaps not more natural, it having the cloſeſt poſſible affinity to *Cymbidium* and *Dendrobium*. The ſpecies in Swartz are 23, in Willdenow 26. Profeſſor Martyn has, with great induſtry, collected 124 under the original genus. Dr. Swartz mentions 19 new ones as diſcovered in South America by the authors of the Flora Peruviana and Chiloenſis.

Among the genuine ſpecies of *Epidendrum*, as the genus ſtands at preſent, are

E. *cochleatum*, Linn. Sp. Pl. 1351. Curt. Mag. t. 572. Jacq. Ic. Rar. t. 605. Andr. Repoſ. t. 13. A native of Jamaica, and the firſt of its tribe that ever flowered in England. It is cultivated in a ſtove, in rotten bark, contrived ſo as to imitate, as much as poſſible, its natural ſituation in the clefts of aged trees, with occaſional ſupplies of water. The *bulbs* are green and ſmooth, of a compreſſed oval figure, each throwing out from its baſe numerous thick entangled fibres, which naturally adhering to the rugged bark, ſtrongly fix the plant and imbibe nouriſhment for its ſupport. A pair of oblong, rigid, recurved *leaves*, entire, as in all this natural order, ſpring from the ſummit of each bulb, and between them grows a *ſtalk*, about a foot high, bearing a ſpike of ſeveral *flowers*. Theſe are reverſed, the long pale-greeniſh calyx and petals hanging down, while the broad, concave, ſomewhat cordate nectary, of a chocolate hue ſpeckled with green, ſtands erect. The flower has little or no ſmell.

E. *fragrans*. Sw. Prod. 123. (E. cochleatum; Curt. Mag. t. 152.) A native alſo of Jamaica, flowered in the ſtove of Chelſea garden, under Mr. Fairbairn's care, in Feb. 1789. This has much reſemblance to the foregoing, but the *petals* are broader, the *nectary* pale ſtreaked with red, and tipped with a long point, and the flowers have a ſweet ſmell. The *ſtalk* moreover is ſhorter in this ſpecies than the *leaves*.

E. *amabile*. Linn. Sp. Pl. 1351. (Angræcum album majus; Rumph. Amb. lib. xi. 99. t. 43.) Native of the Eaſt Indies. This has beautiful white *bloſſoms*, twice as large as in Rumphius's plate, on a long ſlender branched *ſtalk*. The lip is five-lobed, and terminates beſides in a pair of very long, taper, almoſt capillary points. It would be a great acquiſition to our ſtoves.

E. *nutans*. Sw. Prod. 121. A native of Jamaica, flowered in Kew gardens in March 1791. This has a leafy *ſtem*, terminated by a ſtalk bearing a few pale *flowers*, whoſe lip is four-lobed. They are about the ſize of E. *fragrans*.

E. *ciliare*. Linn. Sp. Pl. 1349. Curt. Mag. t. 463. is a beautiful and magnificent plant, native of the Weſt Indies, which flowered at Mr. Whitley's nurſery, Old Brompton, for ſeveral years before 1799. *(Curtis.)* The *flowers* are numerous and fragrant; their calyx-leaves and petals each near two inches long, of a yellowiſh buff-colour; lip white, with two elegantly fringed lobes. This ſpecies is now not very rare in the Engliſh ſtoves.

E. *fuſcatum*. Sm. Spicil. t. 23. is rather ſingular than ornamental. The late Hon. Mrs. Barrington received it from Jamaica, and it bloſſomed in her garden in 1791. The *ſtem* is leafy, and terminates in a very long ſimple ſcaly ſtalk, bearing a denſe corymbus of ſmall *flowers*, which, like the whole plant, are of a brown purpliſh hue.

Several ſpecies, more or leſs a-kin to this laſt, occur in the works of Jacquin, as well as ſome more ſplendid ones with tall branching ſtalks, none of them yet introduced into our gardens.

EPIDERMIS, in *Anatomy*, is the thin inſenſible membrane which covers the true ſkin, and which conſtitutes, therefore, in all parts, the external ſurface of the body. See Skin.

Epidermis, in *Vegetable Anatomy*, from επι, *upon*, and δερας, the *ſkin*, or *hide*, is the ſcarf ſkin, or pellicle, which covers every part of a living plant, as a ſimilar cuticle covers the human ſkin. In the tender growing parts of vegetables this membrane is of the moſt delicate texture, pellucid and colourleſs, extremely thin, yet not deſtitute of tenacity, being wonderfully extenſible on ſtalks, or other parts, of quick growth. Under a high magnifier it is found to be porous in a regular manner, and differently in different plants, ſo as to allow of the paſſage of fluids in a definite degree, in either direction, according to the nature of each plant. Hence ſome leaves perſpire ſlowly, but imbibe moiſture with great rapidity, as thoſe of the ſucculent tribes; while others tranſmit their fluids, or imbibe external moiſture, with nearly equal facility, as aquatics. Such differences are detected by experience, but ſcarcely diſcoverable by microſcopical inveſtigation.

The *Epidermis* is of the moſt eſſential importance to the life of the plant, as of the animal, protecting the living parts which it covers from the injuries of the air, while it allows of due perſpiration and abſorption, as well as of the action of light through its nearly colourleſs ſubſtance. It differs greatly in thickneſs according to the part of the plant to which it belongs. Exquiſitely delicate on the fine organs of a flower, like the cuticle of the animal eye, it has conſiderably more ſubſtance on the leaf, and ſtill more on the branch of a tree. On old trunks it is generally obliterated or deſtroyed, being there no longer neceſſary, the dead layers of bark, (ſee Bark and Cortex,) anſwering all the purpoſes of protection, while the peculiar functions of an organized porous *epidermis* are not wanted. Yet in the birch, and a few other trees, the membrane in queſtion conſiſts of multiplied permanent layers, like the bark, and clothes the trunk as long as that part exiſts. The cuticle is eaſily ſeparable from young ſtalks in a rapid ſtate of vegetation, and from any part of a plant by means of maceration, boiling or putrefaction, being nearly, if not abſolutely, deſtitute of vitality, and very little ſubject to decompoſition.

Beſides the eſſential office of a guard to the living vegetable body againſt all hurtful ſtimulants, the *epidermis* anſwers many ſecondary purpoſes of protection. When naked, as uſual, it proves but a feeble defence againſt heat or cold, but it is often covered with hair or wool, in which caſe it becomes a very powerful one, particularly againſt the too violent action of a burning ſun. Flowers indeed, though peculiarly preſented to all the force of this luminary, have ſcarcely ever any ſuch woolly or downy defence; for the functions which they have to perform are often urgent with reſpect to light and heat. Many petals, notwithſtanding, are ſilky or downy on their outſide, apparently to protect them from cold, or poſſibly from too ſcorching a heat before they are full-grown, examples of which may be ſeen in *Convolvulus*, *Anemone*, and ſeveral other genera; but the inſides of ſuch petals are exquiſitely ſmooth.

Examples of a very firm ſmooth *epidermis*, of conſiderable ſtrength and thickneſs, may be found in the common currant, *Ribes rubrum*, the elder, *Sambucus nigra*, and the laburnum, *Cytiſus Laburnum*. On the branches of the latter it acquires almoſt a horny hardneſs; but it is ſtill more cartilaginous in the hard white tubercles ſprinkled over the leaves of *Aloe perlata*, and in the teeth of the foliage of ſome *Saxifragæ*, as well as the briſtly warts of ſeveral ſpecies of *Echium* and others of the *aſperifoliæ*. On the leaf of the white willow, and the *Protea argentea*, the cuticle has a fine ſilky clothing of a ſilvery hue; while in many more plants it is equally white, but deſtitute of gloſs. In the leaf of many kinds of mullein, *Verbaſcum*, and the fruit of the peach, we find it denſely covered with hairs, more or leſs branched. The herbage of the betony, *Betonica officinalis*, is clothed with rigid briſtles, fixed upon the cuticle, which in a dry ſtate excite ſneezing. Similar hairs on the cuticle of the ſtinging nettle are curiouſly perforated, to tranſmit a venomous fluid lodged in bags at their baſe, like the poiſon in a ſerpent's tooth. Graſſes, corn and horſetail, *Equiſetum*, have much flinty earth in their *epidermis*; while in the corktree, the common maple, and the Dutch elm, the ſame part is of a ſoft elaſtic fungous ſubſtance. The fruit of the plum, and leaves of the cabbage, have their *epidermis* covered with a fine blueiſh powdery reſinous ſecretion, which will ſcarcely allow rain to come in contact with them, yet ſuch plants readily abſorb moiſture.

Nothing can be more abſurd than the idea which ſome philoſophers have formerly entertained, that the *epidermis* was deſtined to give ſhape to a plant, and that certain lumps or excreſcences on the ſtems of trees were originally owing to a caſual wound or crack in this membrane. This opinion is eaſily refuted by purpoſely making ſuch a wound or opening, when it will be found that no tumour can be produced by any ſuch means; ſpontaneous tumours being in reality the cauſe, not the effect, of the burſting of the *epidermis*. S.

EPIDICASIA, Επιδικασια, among the *Athenians*. Daughters, inheriting their parents' eſtate, were obliged to marry their neareſt relations; which gave occaſion to perſons of the ſame family to go to law with one another, each pretending to be more nearly allied to the heireſs than the reſt. The ſuit was called επιδικασιας δικη; and the virgin, about whom the relations conteſted, επιδικος. Pott. Archæol. Græc. lib. 1. cap. 24. tom. i. p. 147.

EPIDIDIUM, in *Ancient Geography*, is the name which Ptolemy gave to that peninſula on the weſtern coaſt of Scotland, which forms part of the county of Argyle, called Cantyre and Knapdale; and including the iſles of Iſlay and Jura, which the Roman geographer conſidered as being part of it: but whether it then was integral, or not, cannot be aſcertained from his account. The peninſula might at an early period have been an iſland; ſuch changes has the ſea made upon our ſurge-beat coaſts: for "Dr. Smith derives this name from a ſimilar Celtic word, ſignifying the iſle of the Picts, who at that time were the principal inhabitants of that part of Scotland." Sir John Sinclair's Stat. Acc. vol. x. p. 519. But ſuch a concluſion is not juſtifiable by the rules of Celtic derivation. *Cyn*, in that language, ſignifies a wedge, and *tor*, land or territory; it is, therefore, obviouſly derived from thoſe two etymons conjoined, perfectly deſcriptive of ſuch a tongue of land, *i. e.* a wedge-ſhaped territory. Mr. Baxter imagines the Pepidii, ſynonymous with Epidii, to have derived their name from the Britiſh word Papidiauc, which ſignifies any thing ſhaped like a flute or pipe, as was the peninſula of Cantyre, the country of the Pepidii. From the ſouthern point, called the mull of Cantyre, promontorium Epidium, the coaſt of Ireland may be plainly ſeen; it being only 16 miles to the ſouth foreland in Coleraine.

EPIDIDYMIS, in *Anatomy*, a part of the teſticle, ſituated behind the body of that organ, and conſiſting of its excretory duct in a wonderfully convoluted form. It ends in a ſtraight tube, called the vas deferens. See Testis.

EPIDO'SIS, from επιδιδωμι, *to increaſe*, in *Surgery*, a preternatural enlargement of parts.

EPIDOT. See Strahlstein.

EPIDOTES, from επιδιδωμι, *I cauſe to grow*, in *Mythology*, deities which were ſuppoſed to preſide over the growth of infants.

EPIDROME, from επι, *upon*, and δρεμω, *to run*, in *Surgery*, an afflux of fluids, or, as they were formerly phraſed, humours, eſpecially when it aroſe from the application of a ligature round any part.

EPIDROMUS, of επι and δρομος, *courſe*, in the *Ancient Shipping*, a ſail near the ſtern, which was the largeſt but one in the ſhip.

EPIECIA, in *Ancient Geography*, a town of Greece, towards the ſea, and not far from Corinth; N. of Tenea.

EPIEZ, in *Geography*, a town of France, in the department of the Loiret, and diſtrict of Beaugency; 12 miles E. of Orleans.

EPIGÆA, in *Botany*, from επι, *upon*, and γεα, *the earth*, expreſſive of the proſtrate growth of this humble ſhrub. Linn. Gen. 219. Schreb. 295. Willd. Sp. Pl. v. 2. 615. Mart. Mill. Dict. v. 2. Juſſ. 161. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Ericæ*, Juſſ.

Gen. Ch. *Cal.* Perianths double, cloſe together, permanent; the outer of three ovato-lanceolate, pointed leaves, of which the external one is larger than the reſt; inner in five deep, upright, lanceolate, pointed ſegments, ſomewhat longer than the outer. *Cor.* of one petal, ſalver-ſhaped; tube rather longer than the calyx, hairy within; limb ſpreading, in five deep ovate-oblong lobes. *Stam.* Filaments ten, thread-ſhaped, the length of the tube, and inſerted into its baſe; anthers oblong, acute. *Piſt.* Germen globoſe, with five furrows, downy; ſtyle cylindrical, as long as the ſtamens; ſtigma obtuſe, in five lobes. *Peric.* Capſule nearly globular, depreſſed, with five angles, five cells, and five valves. *Seeds* numerous, roundiſh. *Receptacle* large, ſeparating into five parts.

Eſſ. Ch. Outer calyx of three leaves; inner in five deep ſegments. Corolla ſalver-ſhaped. Capſule of five cells, with a central five-parted receptacle bearing the ſeeds.

The ſpecies are two.

1. E. *repens.* Linn. Sp. Pl. 565. Swartz Prod. 74. Andr. Repoſ. t. 102. Lamarck Illuſtr. t. 367. f. 1. "Leaves ovate, inclining to heart-ſhaped, entire. Tube of the corolla cylindrical." Native of pine foreſts in Virginia and Canada, but, like many plants of a cold or alpine climate, difficult to preſerve in our gardens. It flowers in April or May. The *root* throws out many woody, procumbent, creeping, branched, hairy, leafy *ſtems*, which form wide-ſpreading patches. *Leaves* alternate, on hairy foot-ſtalks, ovate, obtuſe, entire, heart-ſhaped at the baſe, veiny, ſhining, but roughiſh to the touch. *Stipulas* none. *Flowers* in terminal, denſe, bracteated cluſters, fragrant, of a pale bluſh-colour, each about the ſize of a ſmall cowſlip. It is increaſed by parting the roots, thrives in a light ſandy loam, but requires the ſhelter of a long-continued deep ſnow, or ſome equivalent protection, to ſurvive our winters. We ſaw it in great perfection at Meſſis. Lee and Kennedy's nurſery, Hammerſmith, in 1797.

2. E. *cordifolia.* Swartz Prod. 73. Lamarck Illuſtr. t. 367. f. 2. "Leaves heart-ſhaped, roundiſh, ſerrated, convex, hiſpid, rigid. Tube of the corolla ovate." Native of boggy places on the higheſt mountains of Guadaloupe and Cayenne. Smaller than the former, with pointed and more hiſpid *leaves*, whoſe foot-ſtalks are very ſhort. *Flowers* in like manner terminal, but with a more inflated tube. The young ſhoots are very hairy.

Epigæa, in *Gardening*, comprehends a plant of the low, trailing, ſhrubby, flowering kind. This is the creeping epigæa, or trailing arbutus (E. repens).

Method of Culture.—This is readily effected in this plant by the trailing ſtalks, which ſoon put out roots at the joints, and may then be cut off from the old or parent plants, and be ſet out in a ſhady ſituation, where the ſoil is moiſt, in the autumnal ſeaſon, that the plants may be well eſtabliſhed before the ſpring. In caſes where the winter proves ſevere, it may be neceſſary to lay a few dried leaves, or other light covering over them, to protect them from froſt; but after they become well rooted, they ſeldom require more than being kept clean from weeds.

Theſe are ornamental plants in the fronts of the borders of ſhrubberies.

EPIGASTRIC Artery, in *Surgery.* The proper mode of operating in certain caſes of ruptures, ſo as not to run any riſk of wounding this veſſel, will be explained in the article Hernia.

Epigrastric *Region*, in *Anatomy*, one of thoſe portions, into which the cavity of the abdomen is divided by anatomiſts in their deſcriptions. "The epigaſtric region," ſays Winſlow, "begins immediately under the appendix enſiformis at a ſmall ſuperficial depreſſion, called the pit of the ſtomach, and in adult ſubjects ends above the navel at a tranſverſe line, ſuppoſed to be drawn between the laſt falſe ribs on each ſide.

"This region is ſubdivided into three parts, one middle, named epigaſtrium, and two lateral, termed hypochondria. The epigaſtrium takes in all that ſpace which lies between the falſe ribs of both ſides, and the hypochondria are the ſpaces covered by the falſe ribs." Sect. 7. § 79, and 80.

EPIGASTRIUM. See Epigastric.

EPIGINOMENA, of επιγινομαι, *I ſupervene*, in *Medicine*, are new ſymptoms which occur in the progreſs of a diſeaſe. See Epiphenomena.

EPIGLOTTIS, in *Anatomy*, is a ſmall and thin piece of cartilage, placed at the back of the tongue, and having the office of cloſing the glottis, or opening of communication between the larynx and pharynx, when the food is paſſing into the latter cavity from the mouth. The anatomical deſcription of this part will be found in the article Larynx; its offices are deſcribed in that of Deglutition.

EPIGONIUM, επιγονιον, a muſical inſtrument among the ancients, with forty ſtrings, ſo called from its inventor Epigonius, a native of Ambracia, a city of Epirus. Mem. Acad. Inſcript. vol. v. p. 167.

EPIGONIUS, in *Biography*, was a mathematician of Sicyon, and a native of Ambracia, who is celebrated by the ancients for the invention of an inſtrument of forty ſtrings, which was called after his name, Epigonium. When he lived is uncertain, but as it was in times of ſimplicity, we may ſuppoſe that theſe ſtrings did not form a ſcale of forty different ſounds, but that they were either tuned in uniſons and octaves to each other, or accommodated to different modes and genera. The 12 ſemi-tones of our three-ſtopt harpſichords included thirty-ſix different ſtrings.

The Greeks were divided into numerous ſects of muſical ſpeculators, before and after the time of Ariſtoxenus: as the Epigonians, Damonians, Eratoclians, Agenorians, and many others enumerated by Porphyry, in his Commentary on the Harmonics of Ptolemy. Of theſe, however, all we know is, that they *differed*; it is, perhaps, little to be lamented, that we no longer know about *what.*

Muſic has many obligations to Epigonius. He was the firſt who played on ſtringed inſtruments without a *plectrum.* And, according to Athenæus, he firſt united the melody of flutes to that of the citharas; and by this means ſoftened the harſhneſs and inflexibility of the citharas when played alone. He invented the chromatic genus, and was the original author of choruſes.

EPIGRAM, in *Poetry*, a ſhort poem, or compoſition in verſe, treating only of one thing, and ending with ſome point, or lively ingenious thought.

The word is formed of επιγραμμα, *inſcription*, of επιγραφειν, *to inſcribe*, or *write upon.*

Epigrams then, originally, ſignify *inſcriptions*, and they derive their origin from thoſe inſcriptions placed by the ancients on their tombs, ſtatues, temples, triumphal arches, &c. See Inscription.

Theſe, at firſt, were only ſimple monograms: afterwards increaſing their length, they made them in verſe, to be the more eaſily retained: Herodotus, and others, have tranſmitted to us ſeveral of them.

Such little poems retained the name of epigrams, even after the deſign of their firſt inſtitution was varied, and people began to uſe them for the relation of little facts and accidents, the characteriſing of perſons, &c.

The Greeks confine their epigrams to a very narrow compaſs; for though, in the Anthology, we here and there meet with a very long one; yet, ordinarily, they do not exceed ſix, or, at moſt, eight verſes. The Latins were not always ſo ſcrupulous, and the moderns much leſs, as to theſe bounds.

M. le Brun, in the preface to his "Epigrams," defines an epigram a little poem, ſuſceptible of all kinds of ſubjects, and ending with a lively, juſt, and unexpected thought; which are three qualifications eſſential to the epigram; particularly the firſt and laſt of them, *viz.* brevity, and the point or cloſe of the epigram.

To attain brevity, only one thing is to be aimed at in the poem, and that to be purſued in the conciſeſt terms poſſible. Authors are much divided as to the length the epigram is to be confined to; the ordinary limits are from two to twenty verſes; though we have inſtances, both among the ancients and moderns, where they extend to fifty. But ſtill it is allowed, that the ſhorter the better, and more perfect, as it partakes more of the nature and character of this kind of poem. The point or turn is a quality much inſiſted on by the critics, who require the epigram conſtantly to cloſe with ſomething poignant and unexpected, to which all the reſt of the compoſition is only preparatory. Others there are, who exclude the point, and require the thought to be equally diffuſed throughout the whole poem, without laying the whole ſtreſs on the cloſe: the former is uſually Martial's practice, and the latter that of Catullus. Which is the moſt beautiful and perfect manner is diſputed by a third claſs of critics.

The Greek epigrams have ſcarce any thing of the point or briſkneſs of the Latin ones: thoſe collected in the Anthology have moſt of them a remarkable air of eaſe and ſimplicity, attended with ſomething juſt and witty; ſuch as we find in a ſenſible peaſant, or a child that has wit. They have nothing that bites, but ſomething that tickles. Though they want the ſalt of Martial, yet, to a good taſte, they are not inſipid; except a few of them, which are quite flat and ſpiritleſs. However, the general faintneſs, and delicacy of the pleaſantry in them, has given occaſion for a Greek epigram, or "epigram â la Greque," to denote, among the French, an epigram void of ſalt or ſharpneſs.

It is principally the point that characterizes the epigram, and diſtinguiſhes it from the madrigal. See Point.

In the modern verſification, as obſerved by F. Mourgues, the epigram and madrigal are diſtinguiſhed by the number of verſes and the cloſe. 1. By the number of verſes, which in the modern epigram does not go beyond eight, nor in the modern madrigal comes ſhort of ſix; and, 2. In that the cloſe, or period, of the epigram, has always ſomething more lively and ſtudied than that of the madrigal.

The epigram is the loweſt, and leaſt conſiderable of all the productions of poetry; and it is in general rather an effect of good luck, than of art, to ſucceed therein. The fineſſe, and ſubtilty, of the epigram, M. Boileau obſerves, ſhould turn on the words rather than the thought; which ſeems very little to the credit of this kind of compoſition, as it reduces it to the nature of the pun, or equivoque. F. Bouhours confirms the hint, in adding that the equivoque is what uſually ſhines the moſt in the epigram.

One great beauty of the epigram is, to leave ſomething for the reader to gueſs, or ſupply. Nothing pleaſes the mind ſo much, as to find ſomething in itſelf in the objects preſented it; nor does any thing diſguſt it more than to preclude it from ſhewing and exerciſing a faculty it values itſelf for. Segrais.

The epigram admits of great variety of ſubjects: ſome are made to praiſe, and others to ſatirize, which laſt are much the eaſieſt; ill-nature ſerving inſtead of point and wit. Boileau's epigrams are all ſatires on one or another. Thoſe of Des Reaux are all made in honour of his friends; and thoſe of Mad. Scudery are ſo many eloges. The epigram being only a ſingle thought, it would be ridiculous to expreſs it in a greater number of verſes; it muſt have its unity like the drama. The comedy has an action for its ſubject, and the epigram a thought.

We might ſelect a number of excellent epigrams in our own language, if our limits allowed of enlarging this article. We ſhall content ourſelves with ſubjoining the following. The firſt is that of Mr. Pope, ſaid to be written on a glaſs with the earl of Cheſterfield's diamond pencil.

> "Accept a miracle, inſtead of wit,
> See two dull lines by Stanhope's pencil writ."

The next is an epigram, expreſſed conciſely and cloſing beautifully, which was written on the leaves of a fan by Dr. Atterbury, late biſhop of Rocheſter:

> "Flavia the leaſt and ſlighteſt toy
> Can with reſiſtleſs art employ.
> This fan in meaner hands would prove
> An engine of ſmall force in love;
> Yet ſhe with graceful air and mien,
> Not to be told or ſafely ſeen,
> Directs its wanton motion ſo,
> That it wounds more than Cupid's bow.
> Gives coolneſs to the matchleſs dame,
> To every other breaſt a flame."

Mr. Prior laſhed the impertinence of a bad writer, who had taken the liberty of cenſuring him, in the following epigram:

> "While faſter than his coſtive brain indites,
> Philo's quick hand in flowing letters writes.
> His caſe appears to me like honeſt Teague's,
> When he was run away with by his legs:
> Phoclus, give Philo o'er himſelf command;
> Quicken his ſenſes, or reſtrain his hand.
> Let him be kept from paper, pen, and ink,
> So he may ceaſe to write, and learn to think."

The following epigram was written by Mr. Weſley, on occaſion of erecting a monument to Mr. Butler, author of Hudibras, in Weſtminſter Abbey:

> "While Butler, needy wretch, was yet alive,
> No generous patron, would a dinner give.
> See him, when ſtarv'd to death, and turn'd to duſt,
> Preſented with a monumental buſt!
> The poet's fate is here in emblem ſhown,
> He aſk'd for *bread*, and he receiv'd a *ſtone*."

See Butler.

EPIGRAPHE, Επιγραφη, *Superſcription*, an inſcription on a building, to ſignify its uſe, occaſion, the time when, and the perſon by whom it was built.

EPIGRAPHES, Επιγραφεις, among the Athenians, officers that rated all thoſe of whom taxes and contributions were required, according to every man's ability, kept the public accounts, and proſecuted ſuch as were behindhand with their contributions. Potter. Archæol. Græc. lib. i. cap. 14. tom. i. p. 81.

EPILA, in *Geography*, a town of Spain, in the province of Arragon, on the Xiloca; 17 miles W. of Saragoſſa.

EPILEPSY, in *Medicine*, ἐπιληψία, and ἐπιληψις, ſignifying *ſudden ſeizure*, is a diſeaſe which conſiſts of convulſions of the greater part of the muſcles of voluntary motion, attended with a loſs of ſenſe and feeling, and ending in a ſtate of inſenſibility, and ſeeming ſleep.

This diſeaſe has received a variety of denominations, eſpecially among the ancient writers. By the early Greeks it was called the *ſacred diſeaſe*, from a notion of its origin in ſupernatural influence ; ſome of the exorciſts and impoſtors of thoſe times even pretended to decide, from variations in the ſymptoms, whether the fits were occaſioned by Cybele, Neptune, Mars, or ſome of the heroes. Hippocrates ſeems to have been the firſt who combated theſe abſurd notions of his countrymen ; and ſeverely reprehends the impoſtures of the exorciſts, in pretending to ſet aſide what more than human power had inflicted, by incantations, magic ceremonies, and ſometimes by the moſt contemptible juggling. (See Hippoc. de *Morbo Sacro.*) Aretæus, however, remarks that it might have the denomination of *ſacred* on other accounts ; either from its magnitude, every thing great being deemed ſacred ; or becauſe it could not be removed by human means, but only by divine power ; or from the opinion that a dæmon had entered into the patient, or for all theſe reaſons together. (De Cauſis Affect. lib. i. See alſo Cæl. Aurelian. De Morb. Chron. lib. i. cap. iv.) In like manner the Romans call every thing remarkable and great "ſacred :" "*ſacra* anchora," "auri *ſacra* fames," &c. (Van Swieten. § 1071.) Upon the ſame ground epilepſy has been called morbus *Herculeus*, the Herculean diſeaſe. By the Romans, it was ſometimes termed morbus *comitialis*, "the aſſembly diſeaſe ;" either becauſe epileptic perſons were more frequently obſerved to be ſeized in a crowd of people, or becauſe the public meetings, called *comitia*, were adjourned if any one happened to be attacked with an epileptic fit. It has likewiſe been termed morbus *caducus*, or "falling ſickneſs," becauſe the patients, when they are ſeized with the paroxyſm, fall down.

The leading features and principal circumſtances of the epileptic convulſions are nearly the ſame in all the different perſons whom the diſeaſe affects. The diſeaſe conſiſts of fits, which attack ſuddenly often thoſe who are ſeemingly in perfect health, and, after laſting for ſome time, paſs off, and leave the perſons again in their uſual ſtate.

The individual attacked loſes ſuddenly all ſenſe and power of directing his muſcular actions ; ſo that, if ſtanding or ſitting, he falls immediately, or perhaps with convulſions is thrown to the ground. In that ſituation he is agitated with violent convulſive actions, variouſly moving his limbs and the trunk of his body, with a force that is altogether preternatural. Commonly the limbs on one ſide of the body are more violently agitated than thoſe upon the other. In all caſes the muſcles of the face and eyes are much affected, exhibiting various and violent diſtortions of the countenance. The tongue is often affected, and thruſt out of the mouth, while the muſcles of the lower jaw are alſo affected, and, ſhutting the mouth with violence, often wound the tongue grievouſly. While theſe convulſions continue, the face becomes red, then livid and ſwelled, from the interruption to the circulation through the head, and there is commonly at the ſame time a frothy moiſture iſſuing from the mouth ; and in the moſt ſevere caſes the urine and alvine excrements are involuntarily diſcharged. In ſome inſtances a hiſſing or ſtertorous noiſe is emitted. The convulſions have for a few moments ſome remiſſions, but are ſuddenly again renewed with great violence. Generally, after no long time, this terrible ſtruggle ceaſes altogether, and the patient remains for ſome time without motion, in a ſtate of abſolute inſenſibility, and under the appearance of a profound ſleep. After ſome continuance of this ſeeming ſleep, he ſometimes ſuddenly, but for the moſt part by degrees only, recovers his ſenſes and power of motion, but without any memory of what had paſſed from the firſt ſeizure of the fit, and complaining of head-ache, and exceſſive pain in all the limbs as if from ſevere fatigue. During the convulſions the pulſe and reſpiration are hurried and irregular ; but, when the convulſions ceaſe, they return to their uſual regularity and healthy ſtate.

In moſt caſes the attack of epilepſy comes on ſuddenly, without any warning ſymptom : but ſometimes it is preceded by certain ſenſations for a few moments previous to its actual commencement. Of theſe the moſt remarkable is that, which has been termed the *Aura epileptica* ; which is a ſenſation of ſomething moving in ſome part of the limbs or trunk of the body, and from thence creeping upwards to the head ; and when it arrives there, the perſon is immediately deprived of ſenſe, and falls into an epileptic fit. This feeling is deſcribed ſometimes as reſembling that of a cold vapour, ſometimes as like a fluid gliding, and ſometimes like the ſenſation of a ſmall inſect creeping along the body ; and very often the patients can give no other diſtinct idea of their ſenſation, than as in general of ſomething moving along. It might be ſuppoſed that this ſenſation aroſe from ſome affection of the extremity or other part of a nerve, acted upon by ſome irritating cauſe ; and that the ſenſation, therefore, followed the courſe of ſuch a nerve. But it is not found to follow the courſe of any nerve diſtinctly, and it generally ſeems to paſs along the integuments. There are occaſionally alſo other ſymptoms immediately preceding the fit, and generally referred to the head, where no *aura* is perceived. In ſome perſons a giddineſs comes on ; in others a ſpark of light, which increaſed to a bright beam, uſually uſhers in the paroxyſm ; depending probably on the ſudden turgeſcence of the veſſels in the head, which produces preſſure on the optic nerve, and occaſions this depraved ſenſation. Dr. Gregory uſed to mention in his lectures, at the college of Edinburgh, the caſe of an officer, who had a more ſingular perverſion of ſight, previous to the fit of epilepſy ; he always fancied that he ſaw an apparition of an old woman, with a blue cloak, holding a ſtaff in her hand, with which ſhe knocked him down. He alſo mentioned an inſtance of viſual depravation which occurred to Dr. Fothergill ; a young lady, whom the Dr. was attending as an epileptic patient, remarked that he was covered with ſpangles, (the more unuſual as an ornament to a quaker's coat,) and immediately ſhe fell down in a fit.

Under the article CONVULSIONS we have entered into a detail of the circumſtances which conduce to their origin and production ; and as the whole of thoſe obſervations apply to the epileptic convulſions moſt particularly, it will not be here neceſſary to repeat them. We have there ſtated that convulſions occur under two oppoſite conditions of the body, *viz.* of *repletion* and *inanition* ; or, in the language of Dr. Cullen, of *excitement* and *collapſe* (Firſt Lines, § 1286.) : and that various *irritations* in different parts of the body, but eſpecially in the head, give riſe to them in different inſtances.

Sauvages has deſcribed a great variety of ſpecies of epilepſy, which he has diſtinguiſhed chiefly according to the cauſes which produced them. Dr. Cullen has mentioned only three ſpecies, which (as to the utility of diviſion with a view to the curative indications) might be reduced to two. His firſt ſpecies is epilepſia *cerebralis* (from *cerebrum*, the brain), which attacks ſuddenly, without any evident cauſe, or preceding ſenſation, except perhaps a giddineſs or deprivation of ſight ; and includes the *plethoric* epilepſia and eclampſia of Sauvages, as well as his *cachectic* epilepſy. The ſecond ſpecies, is E. *ſympathica*, in which the *aura epileptica*, before deſcribed, precedes the attack ; a circumſtance which is ſcarcely of ſufficient importance to deſignate a ſpecies. The third, E. *occaſionalis*, includes thoſe inſtances of epilepſy which originate from manifeſt and accidental irritation, and which ſubſide when the irritation is removed. Theſe various cauſes of irritation are, wounds, or blows of the head, from falls, and other external injuries; pain in various degrees, as from parturition, dentition, worms in the alimentary canal; indigeſted food, or other ſubſtances in the ſtomach, as narcotic poiſons, ſpirituous liquors, &c; paſſions of the mind, eſpecially fear; and a variety of other ſources of diſturbance to the ſyſtem, as the eruption of ſmall-pox, and other febrile irritations, the venereal orgaſm, intenſe ſtudy, the ſuppreſſion of cuſtomary diſcharges, &c.; and, laſtly, the imitative propenſity, which is particularly conſpicuous in women and children, as illuſtrated at large under the head of CONVULSIONS.

We have there ſtated the impoſſibility of explaining the proximate cauſe of convulſive diſeaſes, in conſequence of our ignorance of the nature of the nervous power, or of the connection between the action of the muſcles and the brain, or the faculty of volition, in a ſtate of health. And it were ſufficient to mention the attempts to reaſon upon the ſubject, which the ableſt phyſicians have made, in order to prove their futility. The learned Boerhaave ſays, (*Aph.* 1086.) "Et patet quidem, cauſam proximam omnis epilepſiæ exquiſitæ ſemper eſſe nimiam cerebri in nervos motorios, nullam in ſentientes, actionem." "It is obvious that the proximate cauſe of every perfect epilepſy is always too great an action of the brain upon the nerves of motion, and too little upon thoſe of ſenſe:" which is only ſtating the fact in other words; for it amounts merely to this: "in every true epilepſy the motions of the body are violent, and the ſenſe is loſt: the proximate cauſe is ſtill as obſcure as before." Dr. Cullen ſcarcely pretends to form a theory upon the ſubject. "I might ſay," he obſerves, "that it is an affection of the energy of the brain, which, ordinarily under the direction of the will, is here, without any concurrence of it, impelled by preternatural cauſes. But I could go no further: for as to what is the mechanical condition of the brain, in the ordinary exertions of the will, I have no diſtinct knowledge; and therefore muſt be alſo ignorant of the preternatural ſtate of the ſame energy of the brain under the irregular motions here produced." (Firſt Lines, § 1284.) The indications of cure therefore cannot be formed from a knowledge of the proximate cauſe of the diſeaſe; but we obtain ſome uſeful intimations for the treatment, by diligently attending to the various remote cauſes; both thoſe which induce a prediſpoſition, and thoſe which occaſionally excite the diſeaſe. Our principal object, then, will be to avoid the occaſional cauſes, and to remove or correct the prediſponent.

The prediſpoſition to epilepſy, in the majority of inſtances, ſeems to conſiſt partly in what may be termed a morbid irritability, or mobility, of conſtitution, in which the action of ſlight irritations (which are applied to moſt perſons with impunity) excites great commotion in the nervous ſyſtem; and partly in a turgeſcence of the veſſels of the head, which accompanies a general plethora. This appears from the circumſtances, that plethoric perſons are very frequently the ſubjects of epilepſy; that it is often brought on by cauſes inducing any unuſual turgeſcence of the blood-veſſels; and that it has been frequently cured by diminiſhing the plethoric ſtate of the body, more frequently, we believe, than by any other ſyſtem of practice. This principle was inculcated by Dr. Cullen, and is ſtrenuouſly adopted by the preſent Dr. Gregory, his ſucceſſor. It was likewiſe maintained by the late Dr. Fothergill, who has left us the following excellent remarks on this point of practice.

After ſtating that many epilepſies occurred to him, which eluded all his endeavours to relieve them by means of the medicines ordinarily recommended as ſpecifics, and which therefore ſuggeſted the neceſſity of adpoting ſome other mode of procedure, he ſays, "I had obſerved that fits were moſt liable to return in the plenitude of health; that epileptics were often extremely incautious in reſpect to diet; that children, highly indulged, were liable to the diſeaſe; that in every other period of juveneſcence, and in middle aged adults, if they were at all ſubject to the diſeaſe, it was when they had either committed ſome exceſſes, or, by one means or another, were plethoric; and that, in habits ſubject to epilepſy, the diſeaſe ſeldom recurred, without either an habitual indulgence in eating, or a neglect of neceſſary exerciſe. This induced me to recommend, in many caſes, a total abſtinence from all animal food, and from all fermented liquors. Care was taken to regulate the ſecretions, and ſuch a courſe of medicine preſcribed, as might ſeem expedient to induce the patients, or their friends, ſcrupulouſly to comply with ſuch a courſe of diet. It was in vain to reſtrict the quantity of animal food. There are few who have, at all times, reſolution enough to ſubmit to the firſt intimations of ſatiety. It was, therefore, neceſſary to enjoin ſuch a kind of diet, as was accompanied with but ſlender provocations to exceſs, and which, at the ſame time, would afford the leaſt quantity of nutriment; by which that fullneſs, which, in many epileptic caſes, appears to be a ſtimulus ſufficient to produce the ſpaſms, would be avoided, and the parts, which were the immediate ſeat of irritation, might gradually recover a degree of ſtrength and firmneſs, that would be proof againſt every ſlight impreſſion.

"It often happens in diſeaſes, that a proper plan of diet is of much more importance in the cure than any thing we are acquainted with in the *Materia Medica*: it is, however, of not leſs neceſſity to engage the patients and their friends in a ſteady perſeverance of the method we direct. The generality of people have very little notion that diet can do more than merely ſupport their ſtrength; that it can be made ſubſervient to the cure of their diſeaſes, they cannot eaſily be brought to comprehend, &c.

"In young boys, I apprehend, the epilepſy moſt generally proceeds from their own craving appetites, and the neglect of thoſe who are about them. It may not be improbable, but in ſuch caſes worms may alſo have a ſhare in producing the fits. Be this as it may, anthelmintics, however powerful, ſeldom cure the diſeaſe; they may abate occaſionally the frequency, or the violence of the attacks, but they too often, at the ſame time, bring on a greater degree of irritability, and at length, if repeated frequently, and in conſiderahle doſes, ſeldom fail of confirming the diſeaſe. Moderate laxatives, with a light chalybeate interpoſed, and ſteadily continued, with a courſe of diet, conſiſting of milk, vegetables, fruit, and things prepared from them, and in moderate quantities, ſeldom fail of removing the diſeaſe in ſuch habits. Riding and bathing in cold water, and the uſual means of eſtabliſhing good health, muſt, at the ſame time, be attended to, and the plan purſued with patience; for it is not to be expected in diſeaſes that affect the nervous ſyſtem, the moſt remote and fineſt part of the economy, when once they have debilitated, or otherwiſe diſordered, theſe very feeling parts, and their influence is become habitual, that after-medicines, however active, penetrating, and efficacious, can, in a very ſhort time, reſtore the ability to perform their functions as they ought to do." (See Medical Obſ. and Inquiries, vol. vi. p. 72.)

This plan of light and moderate living, with occaſional laxatives, ſhould be adopted in every caſe of epilepſy, where it does not ariſe from loſs of blood, or other cauſes of inanition, or is not connected with a cachectic or emaciated habit: and even in the laſt caſe, the plan is often uſeful, eſpecially where a morbid change, ſuch as exoſtoſis, ſuppuration, or tumour of any kind, is going on in the head.

It might be ſuppoſed that artificial evacuations, eſpecially blood-letting, would be the moſt effectual means of diminiſhing the plethoric ſtate of the ſyſtem: and ſuch it certainly proves, when the plethora has become conſiderable; and if it threatens immediate diſeaſe, this evacuation ought to be made to the quantity that the urgency of the ſymptoms ſeems to require. It is, however, a matter of old obſervation, that blood-letting is not the proper mode of preventing the recurrence of the plethoric ſtate; but, on the contrary, that it is often the means of favouring it, eſpecially when the operation is performed at regular periods. There is, however, a caſe of epilepſy, as Dr. Cullen remarks, in which there is a periodical or occaſional recurrence of the fullneſs and turgeſcence of the ſanguiferous ſyſtem, giving occaſion to a recurrence of the diſeaſe. In ſuch caſes, when the means of preventing plethora have been neglected, or may have proved ineffectual, it is abſolutely neceſſary for the practitioner to watch the returns of theſe turgeſcences, and to obviate their effects by the only certain means of doing it, that is, by a large blood-letting. When the general plethora is not great, but the ſymptoms indicate conſiderable local turgeſcence in the head, the application of cupping-glaſſes, after ſcarification of the neck, or the uſe of a ſeton, bliſter, or iſſue, near the ſame part, will afford the means of ſome relief, by the evacuations which they produce. An open iſſue, indeed, in diſtant parts, as in the arm, has been found uſeful in ſome inſtances of epilepſy, by tending to obviate the plethoric ſtate, or, as Dr. Cullen ſuggeſts, by determining occaſional turgeſcences to thoſe parts, and, therefore, diverting them, in ſome meaſure, from their action upon the brain.

Epilepſy, however, as we have already ſtated, is alſo the reſult of a ſtate of debility, with which the exceſſive nervous mobility that is eaſily excited to convulſions is, in many other inſtances, obſerved to be connected; eſpecially in hyſteria, in the condition of infancy, &c. Where this debility has been the conſequence of inanition, as from loſs of blood, from previous diſeaſe, and ſo forth, a nouriſhing generous diet will be requiſite to reſtore the ſtrength; and inſtances are occaſionally ſeen, in which the propriety and ſucceſs of this practice are manifeſt. Where there is obviouſly a feeble ſtate of body, with pale complexion, and without any appearances of local plethora, the propriety of being much in the open air, of uſing the cold bath frequently, and of regular exerciſe, adapted to the ſtrength and habits of the patient, muſt be equally evident. He may ſtill farther contribute to remove debility, and its conſequences, eſpecially that great mobility which is a principal part of the prediſpoſition to epilepſy, by the uſe of tonic and antiſpaſmodic medicines.

By a ſort of routine, too generally purſued by indiſcriminating practitioners, remedies of the laſt mentioned claſſes are moſt commonly given in epileptic caſes, more particularly of late the metallic tonics, while the diet and regimen are not ſufficiently attended to. However, as the circumſtances of the conſtitution occaſionally favour their operation, it cannot be doubted that the diſeaſe has, in many inſtances, been removed by theſe means; and numerous caſes are on record, in which particular ſpecies of tonic remedies have effected the cure of epilepſy. The preparations of iron have been moſt commonly employed for this purpoſe, as the rubigo ferri, or the ſulphat of iron, or its combination with ammonia (ferrum ammoniacale); and cures have been ſaid to be accompliſhed by all theſe preparations. Dr. Cullen, however, obſerves, that he never found them effectual; which he attributes partly to their not having been always employed in the proper circumſtances of the diſeaſe, and partly to the inadequate quantities in which they have been given. (Firſt Lines, § 1335.) A preparation of copper, the cuprum ammoniacum of the Edinburgh Diſpenſatory, has been one of the moſt celebrated of the metallic tonics, and Dr. Cullen admits it to have been often ſucceſsful. It ſhould be given in the doſe of one grain at firſt, twice in the day, and gradually increaſed to as much as the ſtomach will bear. Zinc, eſpecially in the form of flowers of zinc, (as the oxide was formerly denominated,) has been much extolled for its virtues in the cure of epilepſy, and other ſpaſmodic diſeaſes, when it was uſed in ſmall doſes. Much larger quantities of it, however, have been adminiſtered lately, and its character of efficacy has been conſiderably diminiſhed. The ſulphat of zinc, or white vitriol, appears to be a more efficacious tonic. Arſenic has more recently been introduced as a remedy for epilepſy. The ſafety and great powers of this metal, as a medicine, eſpecially in the cure of *periodical* diſorders, ſuch as intermittent fevers, megrim, or intermittent head-ache, &c. have been fully eſtabliſhed, and afford an analogy in its favour. A writer on this ſubject, in the Edin. Med. and Surg. Journal (for July 1809) ſtates, that he has found arſenic ſucceſsful in the cure of epilepſy, when it "occurred in young ſubjects, principally anterior to the age of puberty, and of what is termed a delicate make, and feeble ſtamina, eſpecially when the diſeaſe aſſumes, or very nearly approaches, a periodic form. The drunken epileptic likewiſe, when not of a full plethoric habit, has found a cure from the firm and judicious uſe of this potent remedy, due attention having been paid to the alvine evacuations." There is ſtill another tonic of the metallic claſs, which has lately been recommended as an efficacious remedy for epilepſy, the nitrat of ſilver (or lunar cauſtic), and is ſaid to have cured the diſeaſe, when it had already been of many years ſtanding. (See two caſes of this nature, Med. and Phyſ. Journal, vol. i. p. 184. vol. ii. p. 70.) A quarter of a grain of this active ſubſtance, given three times a day, is a ſufficient doſe for an adult in the beginning; it may be afterwards carefully increaſed.

The vegetable tonics are admitted to poſſeſs leſs efficacy in alleviating this dreadful diſorder. Among theſe the bitters have chiefly been employed, and the cinchona is the moſt active. Like the arſenic, it is eſpecially adapted to thoſe epilepſies which recur at certain periods, and which are not at the ſame time accompanied with any plethoric ſtate, or turgeſcence of the blood: in ſuch periodical caſes, if the bark is employed ſome time before the expected recurrence, it may be uſeful; but it muſt be given in large quantity, and as near to the time of the expected recurrence as poſſible. The leaves of the orange tree have ſometimes proved uſeful in this diſeaſe, probably by the bitter quality which they poſſeſs.

But this caution muſt again be given, with reſpect to the employment of any of the above-mentioned tonics in this diſeaſe, that in all caſes where it depends upon conſtant or occaſional plethoric ſtate of the ſyſtem, theſe medicines are likely to be at leaſt ineffectual; and if ſufficient evacuations be not made at the ſame time, they are likely to be very hurtful. The various ſucceſs with which ſuch remedies have been adminiſtered is, doubtleſs, to be aſcribed partly to inattention to theſe circumſtances; although it is equally clear, that many epilepſies, connected with organic leſion in the head, or a connate diſorder of the habit, are beyond the power of any medicine.

With a view of diminiſhing the tendency to the convulſions of epilepſy, various antiſpaſmodic medicines have been employed, ſuch as valerian, caſtor, muſk, the fœtid gums, empyreumatic oils, and other ſubſtances of ſtrong and offenſive odour. But, although theſe remedies were generally adminiſtered at one period, and were much extolled for their antiſpaſmodic powers, they ſeem to have loſt their high character, in a great meaſure, and are much leſs employed than heretofore.

Several remedies have alſo been introduced, as *ſpecifics*, in the diſeaſe in queſtion; *i. e.* as remedies which poſſeſſed a peculiar influence over it, independently of any ſenſible quality or operation. Such are the viſcus quercinus, or miſletoe, the cardamine pratenſis, agaricus muſcarius, &c. Experience has not ſanctioned the recommendation of theſe medicines, which appear to be nearly inert. If the miſletoe were ever beneficial, it was probably in thoſe times when it was an object of religious ſuperſtition, and operated through the medium of an impreſſion on the mind. On the ſame principle, taking remedies that excited horror may have ſometimes ſucceeded in curing the diſeaſe; ſuch as the powder of human ſkulls, (pulvis cranix,) &c. A pamphlet has been publiſhed lately, however, in which the ſpecific efficacy of the miſletoe is again contended for by Dr. H. Fraſer. But the caſes, there related, are mentioned ſo briefly and uncircumſtantially, that no juſt inference as to the means of cure can be deduced; and the weight of negative evidence is, on the other hand, ſo great, that we are diſpoſed to attach little credit to the miſletoe. We have employed it, ſince the publication of the pamphlet alluded to; but without any effect.

Dr. Fothergill, whoſe experience and ſound obſervation led him to infer, that plethora was the moſt frequent cauſe of *curable* epilepſies, and the ſyſtem of diet and evacuation, before mentioned, the moſt effectual means of cure, was diſpoſed to attribute the reputed efficacy of all the laſt-named remedies for epilepſy to a very different operation, than was intended by the preſcriber: namely, to their impeding digeſtion, and conſequently preventing incurring plethora. "Valerian," he ſays, "caſtor, the fœtid gums, empyreumatic oils, and, if there be any thing ſtill more diſguſtful, commonly make a part of the medicines propoſed for this diſeaſe. There are ſome others, whoſe qualites, indeed, are not quite ſo repugnant to our taſte and ſmell, ſuch as the miſletoe, and the *flores cardamines;* but to balance this difference, it is requiſite to take theſe ſuch a length of time, and in ſuch quantities, as make them not leſs diſguſtful at length. May not, therefore, both theſe kinds of medicines, and moſt of thoſe made uſe of as ſpecifics from ancient authority, now and then confirmed with inſtances of benefit, derive the greateſt part of their conſequence from their quantity, or their diſguſting qualities, which, by leſſening the appetite, allow nature to recover herſelf, and ſhake off a diſeaſe, which indulgence principally produced." (Med. Obſ. and Inquir. vol. vi. p. 77.)

The ſight of others in a fit of epilepſy is the moſt common of the mental irritations which produce epilepſy: this, therefore, ſhould be guarded againſt, eſpecially among children, and more particularly in a family where epilepſy has already appeared. The famous caſes of epilepſy, thus communicated among the orphans at the hoſpital at Haerlem, are well known; (ſee Convulsions,) as well as Boerhaave's ſucceſsful cure, by threatening a ſevere puniſhment (burning with a hot iron) to the firſt who ſhould be ſeized with a fit. This counter-impreſſion upon the mind, which Dr. Cullen whimſically terms the *tonic* of fear, was ſufficient to obviate the effects of the other. (See Kaau Boerhaave impetum faciens, § 406.)

Some anti-epileptic powers have been attributed to opium, hyoſcyamus, or henbane, digitalis, and ſome other ſedative medicines; but it is obvious that theſe ſubſtances can only be ſerviceable in thoſe caſes where the diſeaſe depends upon irritation, or increaſed irritability, when their effects will be temporary; and that, when there is any plethoric or inflammatory condition preſent, they muſt, with the exception of digitalis, prove hurtful, eſpecially opium.

With reſpect to the fit itſelf nothing can be done, in general, except reſtraining the patient from injuring himſelf. He ſhould be removed from the ground, or from the vicinity of any hard body, againſt which he might be bruiſed by the convulſive motions of the limbs; and in thoſe caſes in which the tongue is apt to be protruded, and lacerated by the teeth, a ſort of gag ſhould be introduced. In very plethoric habits, where the determination of blood to the head is very great, it may be adviſeable to open a vein during the fit, in order to obviate the immediate danger of life, from a rupture of the veſſels of the brain.

When the fit is preceded by an *aura*, as before mentioned, which has been ſuppoſed to ariſe from irritation propagated along the courſe of ſome particular nerve, various means of preventing the fit have been ſuggeſted; ſuch as deſtroying the part, in which the *aura epileptica* ariſes, by means of the knife or cauſtic, applying a bliſter, or making an iſſue in it, or cutting the branch of the nerve along which the *aura* ſeems to paſs, or laſtly, applying a ligature upon the limb, above the part from which the *aura* ariſes. A tourniquet has been recommended for the laſt purpoſe, to be worn looſe upon the limb, and tightened the inſtant that the *aura* is perceived; by which means the epilepſy has been ſaid to have been prevented in ſeveral inſtances.

On diſſection after death from epilepſy, a variety of morbid and preternatural appearances have been in the head, to which the ſymptoms might be juſtly attributed, in conſequence of the mechanical irritation of the brain. Thus irregularity in the arrangement of the bones, or ſome other malformation of the cranium, inequalities or protuberances on its interior ſurface, ſplinters, or depreſſion of the bones from fracture; tumours, thickening, and oſſification in the membranes enveloping the brain; fluids of various acrimony effuſed, or collected within the brain, or on its ſurface, and tumours formed in the ſubſtance of the brain; have in various inſtances been diſcovered after epilepſy had proved fatal.

EPILESMON, from επιληθω, *I cauſe to forget*, a term uſed by the old writers in *Medicine*, to expreſs a loſs of memory.

EPILOBIUM, in *Botany*, a name adopted by Conrad Geſner, and explained by him as indicative of the character of this genus, επι λοβȣ ιον, *a violet*, or beautiful flower, growing upon a pod; in which he is followed by Dillenius and Linnæus. See Bauhin's Pinax 245, ſect. 7; Dill. Plantæ Agri Giſſenſis, 132; and Linn. Phil. Bot. 176. Willow-herb.—Linn. Gen. 188. Schreb. 251. Willd. Sp. Pl. v. 2. 313. Sm. Fl. Brit. 409. Mart. Mill. Dict. v. 2. Juſſ. 319. Gærtn. t. 31. (Chamænerion; Tourn. t. 157.) Claſs and order, *Octandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, deeply four-cleft; ſegments oblong, pointed, coloured, deciduous. *Cor.* Petals four, roundiſh, broadeſt upward, cloven, ſpreading, inſerted into the calyx between its ſegments. *Stam.* Filaments eight, awl-ſhaped, alternately ſhorter; anthers oval, compreſſed, obtuſe. *Piſt.* Germen inferior, cylindrical, very long; ſtyle thread-ſhaped; ſtigma thick, obtuſe, either undivided or four-cleft, the lobes revolute, downy. *Peric.* Capſule very long, cylindrical, with four furrows, four cells, and four valves, with a longitudinal linear partition originating from the centre of each. *Recept.* columnar, ſquare, its angles attached to the partitions, which at length ſeparate from it. *Seeds* numerous, oblong, crowned with down, and affixed in two rows to each angle of the receptacle.

Eſſ. Ch. Calyx in four deep ſegments. Petals four. Capſule oblong, inferior. Seeds feathered.

An elegant genus of plants, with flowers of a paler or deeper roſe-colour, natives of watery or boggy ſituations, chiefly in the cooler or mountainous parts of Europe. The *roots* in all are perennial, and often creeping. *Leaves* undivided. *Flowers* ſpiked or racemoſe, terminal. *Stamens* in ſome direct, in others declining.

The ſpecies in Willdenow are twelve, to which are to be added E. *roſeum*, Schreb. Lipſ. 147. Sm. Fl. Brit. 411. Engl. Bot. t. 693, and E. *alſinifolium*, Villars Dauph. v. 3. 511. Engl. Bot. t. 2000, both by him made varieties of E. *montanum*. The Britiſh ſpecies therefore, at preſent aſcertained, are nine.

E. *anguſtifolium*, Linn. Sp. Pl. 493. Curt. Lond. faſc. 2. t. 24. Engl. Bot. t. 1947, called the French or Perſian Willow, or Roſebay Willow-herb, is one of the moſt handſome, though moſt common, of the whole. It rarely with us occurs wild, but thrives and bloſſoms abundantly in any garden, whether the ſituation be moiſt or dry, even in almoſt any part of London. Linnæus ſays, Fl. Lapp. n. 146, "it frequently, like a garden, ſurrounds the hut of the wild Laplander, who vies with Diogenes in the ſimplicity of his houſehold furniture, but whoſe habitation ſeems the palace of a divinity, when this ſtately plant is in bloom." This is an inſtance, among many, of a truly alpine plant ſucceeding well in the ſmoke of a city, while others require the pureſt air poſſible.

EPILOGUE, Epilogus, in *Oratory*, &c. The peroration, or laſt part of a diſcourſe, or treatiſe; containing ordinarily a recapitulation of the principal matters delivered.

The word is Greek, επιλογος, formed of the verb επιλεγω, *I ſay after*; the epilogue being the end, or concluſion of a diſcourſe.

Epilogue, in *Dramatic Poetry*, is a ſpeech addreſſed to the audience, when the play is over, by one of the principal perſons or actors in the piece; containing uſually ſome reflections on certain incidents in the play, particularly thoſe of the part of the perſon who ſpeaks it.

In the modern tragedy, the epilogue has uſually ſomewhat of pleaſantry in it; intended, perhaps, to compoſe the paſſions raiſed in the courſe of the repreſentation, and ſend the audience away in good humour; though how far that deſign is good and laudable will bear ſome diſpute: an ingenious author in the Spectator compares it to a merry jig on the organ, after a good ſermon, to obliterate any impreſſions that might have been made thereby, and ſend the people away juſt as they came.

In effect, though the epilogue, in this ſenſe, may ſeem an abuſe, yet has it the countenance of antiquity; the Romans had ſomething of the ſame nature, though under another name. Their exodium was a kind of farce, brought on the ſtage when the tragedy was over: "ut quicquid lacrymarum ac triſtitiæ cepiſſent ex tragicis affectibus, hujus ſpectaculi riſus detergeret," ſays the ſcholiaſt of Juvenal. The epilogue is but of modern date, much later than the prologue. Many, indeed, have taken the exodium of the ancient Greek drama for an epilogue, becauſe Ariſtotle defines it to be a part rehearſed after the chorus had ſung for the laſt time; but in reality, it was of a quite different nature. The exodium was the laſt of the four parts of the tragedy: containing the unravelling and cataſtrophe of the plot, and anſwering to our laſt, or fifth act.

EPIMEDIUM, in *Botany*, as at preſent underſtood, is certainly different from the επιμηδιον of Dioſcorides, which ſeems to be *Oſmunda Lunaria*, though his deſcription does not exactly agree even with that plant. The derivation of the name has always appeared obſcure. Ambroſini deduces it "from επιμυω, *to cloſe*, or *ſhut up*, becauſe the leaves conceal the flowers; or from επι μηδια, becauſe of its growing frequently in Media." Neither of theſe is ſatiſfactory, and the word ſeems rather to have a reference to the plant μηδιον, a *Campanula*, or ſomething very near that genus, which immediately precedes it in Dioſcorides. However this may be, the name *Epimedium* is now univerſally applied to the Barren-wort. Linn. Gen. 59. Schreb. 79. Willd. Sp. Pl. v. 1. 660. Sm. Fl. Brit. 187. Prod. Fl. Græc. 103. Mart. Mill. Dict. v. 2. Juſſ. 287. Tourn. t. 117. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Corydales*, Linn. *Berberides*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of four ovate, obtuſe, concave, ſmall, ſpreading, deciduous leaves, placed directly under the petals. *Cor.* Petals four, ovate, obtuſe, concave, equal, ſpreading. Nectaries four, pouch-ſhaped, blunt at the baſe, the ſize of the petals and lying upon them, fixed to the receptacle by the edge of their orifice. *Stam.* Filaments four, awl-ſhaped, preſſed cloſe to the ſtyle; anthers oblong, erect, of two cells and two valves, the latter ſeparating from their baſe upwards, leaving the partition free. *Piſt.* Germen ſuperior, oblong; ſtyle ſhorter than the germen, as long as the ſtamens; ſtigma ſimple. *Peric.* Pod oblong, pointed, of one cell and two valves. *Seeds* numerous, oblong.

Eſſ. Ch. Petals four. Nectaries four, pouches lying on the petals. Calyx oppoſite to the petals, caducous. Pod ſuperior, of one cell, with many ſeeds.

E. *alpinum*. Linn. Sp. Pl. 271. Engl. Bot. t. 438. Fl. Græc. ined. t. 150. Ger. em. 480. The only ſpecies, a native of ſhady mountainous places in ſeveral parts of Europe, not very difficult of cultivation in our gardens, flowering in May. The *root* is perennial, creeping, ſlender, blackiſh. *Stems* upright, ſimple, about a foot high, round, ſmooth, bearing one large, twice or thrice compound leaf, divided irregularly in a three-fold order, and compoſed of large, pendent, tremulous, thin, delicate, heart-ſhaped, pointed, finely ciliated, ſmooth leaflets, glaucous beneath; and one upright *panicle*, alternately branched, whoſe ſtalks are red, and rough with glandular hairs. *Flowers* ſingular and elegant, drooping, with dark red petals, and yellow pellucid nectaries. Dr. Smith, in his Engliſh Botany, ſuggeſts that "perhaps what is called the ſtem ought to be reckoned only the footſtalk of the leaf, which, as in *Turnera*, bears the flowerſtalk."

EPIMENIDES, in *Biography*, a Cretan philoſopher and poet, who was contemporary with Solon, and of whom many fables are related. Among others it is ſaid, that, being ſent by his father in ſearch of a ſtraying ſheep, he ſlept in a cave, where he repoſed himſelf for 50 years, and when he awoke, found to his ſurpriſe, that he was become an old man, that every thing about him was become new and ſtrange. It is alſo recorded of him, that he could diſmiſs the ſoul from his body, and recal it at pleaſure; and that he had familiar intercourſe with the gods, and poſſeſſed the gift of prophecy. Moſt of theſe fictions may probably have originated with the Cretans, who were, to a proverb, famous for their powers of invention. (Titus, i. 12.) The more credible account of Epimenides is, that he was a man of ſuperior talents, who pretended to intercourſe with the

the gods, and in order to juſtify his pretenſions, lived in retirement upon the ſpontaneous productions of the earth, and practiſed various arts of impoſture. At the time of his pretended inſpiration he might, poſſibly, have the art of appearing totally inſenſible and entranced, which would be conſidered by ignorant and deluded ſpectators as a power of diſmiſſing and recalling his ſpirit. Such was his reputation for ſanctity, and for the performance of religious rites, that, during a plague in Attica, which happened in the 46th olympiad, about 596 years B.C., the Athenians ſent for him to perform a ſacred luſtration: in conſequence of which, as it is ſaid, the gods were appeaſed and the plague ceaſed. Of this ceremony we have given a particular account under the article ALTAR. On occaſion of this viſit to Athens, Epimenides became acquainted with Solon, the Athenian legiſlator, who is ſaid to have diſapproved the conduct of the Athenians in this inſtance of ſuperſtition; and yet availed himſelf of the advice of the philoſopher in compiling his celebrated code. The Athenians, however, were delivered from the peſtilence, and were diſpoſed liberally to requite Epimenides for his ſervices. The philoſopher declined accepting their offered recompence, and contented himſelf with a branch of the ſacred olive, which grew in their citadel, and with this he returned to his native country, after having concluded a league between the Gnoſſians of Crete and the Athenians. Soon after his return to Crete he died, as Laertius ſays, at the age of 157 years, or, as the Cretans pretend, at the age of 299 years. The ſuperſtitious Cretans paid him divine honours after his deceaſe; and he has been reckoned by ſome the 7th wiſe man of Greece, to the excluſion of Periander from this number. Laertius enumerates a variety of pieces written by Epimenides, both in proſe and verſe. Among the former was a treatiſe "On Sacrifices," and "An Account of the Cretan Republic;" and among the latter "The Genealogy and Theogony of the Curetes and Corybantes," in 5000 verſes; "Of the Building of the ſhip Argo, and Jaſon's Expedition to Colchis," in 6500 verſes; "Of Minos and Rhadamanthus," in 4000 verſes; and a treatiſe "Of Oracles and Reſponſes," mentioned by St. Jerome, from which St. Paul is ſaid to have taken the quotation in his epiſtle to Titus, ch. i. 12. Laert. l. i. c. 10. Brucker's Hiſt. Phil. by Enfield, vol. i.

EPIMETRON, επι and μετρον, *meaſure*, in *Antiquity*, an allowance given the tax-gatherers in the Roman provinces, over and above the juſt quantity of wine or grain they were obliged to furniſh. The epimetron, or over-meaſure, in different provinces, was different, being always greater in thoſe that were remote, than in the nearer provinces. The different kinds of things wherein it was given made likewiſe a difference in the quantity allowed. The reaſon of allowing an epimetron, or over-meaſure, was to make good the leakage of the wine and waſte of grain, that would neceſſarily happen by tranſporting it to Rome.

The provinces whoſe taxes were converted into money, and paid in ſpecie, were free from epimetron.

EPIMORIOS, Επιμοριος, *ſuperparticular*, of μειρω, *I divide*, an epithet given by Galen to certain differences in the pulſes with reſpect to their inequality as to the time of their beating. All times, rythms, or modulations of the pulſe, according to number, conſiſt, he obſerves, of equal or unequal proportions. Of equal, when the time of the diſtenſion is equal to that of contraction; and of unequal, when the one of theſe exceeds the other; and this inequality may be from certain or uncertain exceſſes. The certain exceſſes may be either in multiple proportion, or as number to number, which is the epimorion.

EPIMULIS, of επι, *upon*, and μυλη, *whirle bone on the top of the knee*, a name given, by ſome anatomiſts, to the patella, or knee-pan.

EPIMYLIA, in the *Ancient Muſic.* We are told, in Athenæus, that the epimylia, and the ſong called "Hymæus," were the ſame (ſee HYMÆUS): Athenæus adds, that it is probable that the word epimylia comes from εμυλις, which in Dorian ſignifies ſometimes the return, and ſometimes the augmentation and ſurplus of nouriſhment given to thoſe who labour at the mill. But perhaps after all, this word comes from μυλα, *a mill.*

EPIMYTHION, Επιμυθιον, in *Rhetoric.* See FABLE.

EPINA, or HARPINA, in *Ancient Geography*, a town of Triphylia, upon the river Parthenia, N. of Phryga.

EPINAC, in *Geography*, a ſmall town of France, in the department of Saône and Loire, chief place of a canton in the diſtrict of Autun, with a population of 1128 individuals. The canton contains 11 communes and 5802 inhabitants, on a territorial extent of 155 kiliometres.

EPINAL, or ESPINAL, a town of France, in the department of the Voſges, chief place of the diſtrict of the ſame name, with a population of 7321 individuals. It is ſituated on the river Moſelle, 12 miles N.W. of Remiremont, and 480 miles of Paris, and 42 miles S.E. of Nancy. N. lat. 48° 22'. The canton has a territorial extent of 297½ kiliometres, 19 communes, and 14,709 inhabitants.

As chief place of a diſtrict, Epinal has a ſub-prefect, a ranger, a brigadier-general, who commands in the department, a captain of the national gendarmerie, two courts of juſtice, and a regiſter office. It has ſeveral paper-mills. The ſoil produces wheat, rye, oats, hemp, and flax. Its principal trade is with hemp and flax, hemp and flax ſeed, oil, and the produce of a few manufactures of linen and cotton ſtuffs, and writing paper. The whole diſtrict compriſes five cantons, 116 communes, and 62,592 inhabitants, on a territorial extent of 1285 kiliometres.

EPINAY, a ſmall town of France, in the department of l'Ille and Vilaine; three miles W. of Vitré, which, before the revolution of 1789, conferred the title of marquis on the lord of the manor.

EPINENEUCOS, from νευω, *I nod*, in the old writers of *Medicine*, a word uſed to denote a ſort of unequal pulſe, beating differently in the different parts of the ſame artery; as when it riſes ſtrongly againſt the two middle fingers of the phyſician who feels it, and weaker at the extremes; this ſort of pulſe is deſcribed by Galen as common to hectic patients, and is called alſo perineneucos.

EPINEPHELOS, of επι and νεφηλη, *clouds*, in the *Writings of the Ancient Phyſicians*, a term uſed to expreſs the cloudy matter ſeen floating in the urine in fevers, &c. See ENEOREMA.

EPINETTE, *Fr.* in *Muſic.* See SPINET.

EPINEU *le Chevreuil*, in *Geography*, a town of France, in the department of the Sarte and diſtrict of Sillè; 12 miles W. of Le Mans.

EPINEUL, a town of France, in the department of the Yonne, and diſtrict of Tonnerre; 1½ mile N. of Tonnerre.

EPINEUX *des Lombes*, in *Anatomy*, a name given by Winſlow, and ſome other of the French authors, to certain ſmall muſcles of the loins, not mentioned by the old anatomiſts; but called by Albinus interſpinales lumborum.

EPINICINION, Επινικινιον, in the *Ancient Muſic*, a ſong of victory, by which the Greeks celebrated the triumph of conquerors.

EPINICION, Επινικιον, from επι, *on*, νικη, *victory*, in the *Greek and Latin Poetry*, denotes, 1. A feaſt, ceremony, or rejoicing, on occaſion of a victory obtained. 2. A poem or compoſition, on the ſame ſubject. Scaliger treats expreſsly of the epinicion in the Poetics, lib. i. cap. 44.

EPINOI, in *Geography*, a ſmall town of France, in the department of the North; 9 miles S. of Lille, and 9 miles N. of Douai.

EPINYCTIS, (from επι, and νυξ, *night*,) in *Surgery*, a kind of puſtule, of the nature of the furunculus, originating in the night-time; or, according to Ætius and Paulus, attended at this period with the moſt pain.

EPIODIUM, in the *Ancient Muſic*, a funeral ſong or dirge with the Greeks; called Mænia by the Romans.

EPIPACTIS, in *Botany;* according to Hederic, from επιπηγνυμι, or επιπηγνυω, to congeal, or to grow together at the ſummit. In this ſenſe the name may very well apply to the *Helleborine* of ſome authors, for which Haller and Swartz retain it, and which has always been taken for the επιπακτις of Dioſcorides, whoſe account of the matter is too ſhort and vague to afford much light. The petals of this plant do indeed approach each other, towards the upper part, more than in many of the *Orchideæ*, and ſuch an explanation is more correct than that of Ambroſini, who derives the word from παγος, ice, or πηκτος, frozen, "becauſe the herb grows in very cold places, as it were upon or above the ice;" which circumſtance by no means applies to it. Haller in Act. Helvet. v. 4. 100. Hiſt. Stirp. Helvet. v. 2. 147. Swartz. Act. Holm. 1800. p. 231. t. 3. f. N. Tracts on Botany, 159. Schrad. Neues Journ. v. 1. 62. Willd. Sp. Pl. v. 4. 83. (Helleborine; Tourn. t. 249. Serapias; Linn. Gen. 462. Schreb. 503. Juſſ. 65. Gærtn. t. 14.) Claſs and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. reformed. *Cal.* three-leaved; leaflets direct, a little ſpreading, concave, acute. *Cor.* Petals two, rather ſmaller than the calyx, ſlightly ſpreading. Nectary a lip proceeding from the lower part of the ſtyle, tapering, or concave, or keeled, at the baſe, uſually longer than the calyx, deflexed, entire or cloven, concave or flattiſh, often furrowed above. *Stam.* Anther an hemiſpherical, moveable, permanent, terminal lid, of two cells, attached by its poſterior edge to the top of the ſtyle; maſſes of pollen oblong, powdery, granulated, ſometimes lobed. *Piſt.* Germen inferior, obovate, erect, furrowed, ſometimes twiſted; ſtyle erect, roundiſh, notched at the top; ſtigma in front, oblique, under the anther. *Peric.* Capſule inferior, oval, with ſix ribs and one cell, opening by clefts between the ribs. *Seeds* numerous, minute, tunicate.

Eſſ. Ch. reformed. Calyx-leaves direct, ſlightly ſpreading. Lip without a ſpur. Anther a terminal permanent lid. Pollen powdery, granulated.

Swartz and Willdenow enumerate fourteen ſpecies of this genus, eight or nine of which are Britiſh. They are divided into two ſections, eight of them having an undivided lip, and ſix a cloven one. The former are,

1. E. *latifolia.* (Serapias latifolia; Linn. Syſt. Veg. ed. 14. 814. Sm. Fl. Brit. 942. Engl. Bot. t. 269.) A native of cool, ſhady, rather mountainous woods, throughout Europe. The *roots* are perennial and creeping. *Stems* ſimple, about two feet high, leafy, roughiſh. *Leaves* ovate, or broad-lanceolate, ribbed and plaited, claſping the ſtem alternately. *Flowers* in a long terminal ſpike, with bracteas at leaſt as long as the germen, the lower ones longer than the whole flower. *Calyx* and *petals* of a browniſh green. *Nectary* ſhorter than either, heart-ſhaped in front, purpliſh, acute,

2. E. *paluſtris.* (Serapias paluſtris; Scop. Carn. v. 2. 204. Lightf. 527. Sm. Fl. Brit. 943. Engl. Bot. t. 270.) An elegant native of watery, boggy meadows, in England and other parts of Europe, flowering in July and Auguſt. The *flowers* are fewer, but larger and more ſpecious than the laſt, being variegated with white, purple and yellow, and the lip is crenate. Linnæus has called this S. *longifolia*, but very incorrectly, and from miſtake.

3. E. *microphylla.* Sw. (Serapias parvifolia; Ehrh. Herb. 120.) A native of Germany and Switzerland; poſſibly alſo of England, as we have ſome ſuſpicion of its being the Helleborine altera, atrorubente flore, of Ray's Synopſis, 383. It moſt reſembles the firſt ſpecies, but has much ſmaller leaves.

4. E. *grandiflora.* (E. pallens; Sw. Serapias grandiflora; Sm. Fl. Brit. 944. Engl. Bot. t. 271.) Frequent in the beech woods of Berkſhire and other midland counties of England, flowering in June. The *flowers* are few, cloſed, large and elegant, white with yellow lines upon the lip. *Leaves* elliptical.

5. E. *enſifolia.* Willd. (Serapias enſifolia; Sm. Fl. Brit. 945. Engl. Bot. t. 494. S. xiphophyllum; Linn. Suppl. 404.) Confounded by Haller, Hudſon and others with the laſt, from which it differs in its minute *bracteas*, narrower and longer *leaves*, ſhorter *lip*, and more ſlender *germen*. It grows in Switzerland, and very rarely in the mountainous parts of Yorkſhire and Worceſterſhire.

6. E. *rubra.* (Serapias rubra; Linn. Syſt. Veg. ed. 14. 816. Sm. Fl. Brit. 946. Engl. Bot. t. 437.) Native of ſhady mountainous woods in ſeveral parts of Europe, rare in England. It is diſtinguiſhed by its elegant roſe-coloured *flowers*, whoſe lip is marked with yellow wavy ridges, and auricled at its baſe.

7, 8. E. *erecta* and *falcata*, natives of Japan, are the only remaining ſpecies of this ſection; and theſe, as Willdenow obſerves, appearing to have a ſpur to the flower, are perhaps ſpecies of *Limodorum*.

The ſpecies in Swartz and Willdenow with a cloven lip are,

9. E. *Nidus avis.* (Ophrys Nidus avis; Linn. Sp. Pl. 1339. Sm. Fl. Brit. 931. Engl. Bot. t. 48.) A paraſitical plant, growing in ſhady beech woods, chiefly on a chalky ſoil, and ſingular for its uniform pale brown hue. The *root* conſiſts of numerous cluſtered juicy fibres. *Leaves* none, except ſmall ſcales on the ſtem. *Flowers* numerous, forming a denſe ſpike, inodorous, with a cloven divaricated lip.

10. E. *ovata.* (Ophrys ovata; Linn. Sp. Pl. 1340. Sm. Fl. Brit. 932. Engl. Bot. t. 1548. Curt. Lond. faſc. 3. t. 60.) Frequent in woods, flowering in June like moſt of its genus. The *ſtem*, a foot high, bears only two oppoſite, broad, oval leaves, and a ſpike of numerous ſmall green *flowers*, whoſe long pendulous lip produces a ſmall drop of honey in front, thus proving its right to the title of nectary. See Sm. Introd. to Botany, 461.

11. E. *cordata.* (Ophrys cordata; Linn. Sp. Pl. 1340. Sm. Fl. Brit. 933. Engl. Bot. t. 358.) Grows on boggy mountainous heaths in Scotland and the north of England, as well as in Switzerland, &c. It is ſcarcely a quarter ſo large as the laſt, and has heart-ſhaped *leaves*, and a four-lobed lip.

12. E. *convallarioides.* Sw. in Web. and Mohr. Beitr. v. 1. t. 1. (Ophrys cordata; Michaux Fl. Boreali-Amer. v. 2. 158.) Native of the Weſt Coaſt of North America, and of Newfoundland. A ſlender delicate ſpecies, with a pair of roundiſh heart-ſhaped *leaves*, capillary racemoſe *flower-ſtalks*, narrow *calyx* and *petals*, and a dilated lip.

13. E. *camtſchatea.* Sw. and Willd. (Ophrys camtſchatea; Linn. Sp. Pl. 1343. Neottia; Amœn. Acad. v. 2. 361. t. 4. f. 24.) Native of Siberia. Deſtitute of *leaves*, except a few ſheathing ſcales. The *flowers* are much like the laſt, but have a more linear nectary.

14. E. *unifolia.* (E. porrifolia; Sw. and Willd. Ophrys unifolia; Forſt. Prod. 59.) Found by Forſter in New Zealand. The *leaf* is ſolitary and ſheathing, riſing above the ſtalk, which it embraces, and which bears a ſhort denſe ſpike of ſmall *flowers*. We ſee no advantage in changing the original ſpecific name.

EPIPEDOMETRY, of επι, ϖȣς, *foot*, and μετρω, *I meaſure*, in *Mathematics*, ſignifies the meaſuring of figures that ſtand on the ſame baſe.

EPIPETRON, in *Botany*, a name given, by Theophraſtus and Ariſtotle, to a plant, ſuppoſed by many to be the ſame with the empetrum of Dioſcorides. But there is great reaſon to doubt whether the epipetron of the two older authors be the ſame plant; and whether, if they mean two different plants by this name, either of them agree with the empetrum of Dioſcorides. Theophraſtus ſays, that his epipetron never flowers: and Ariſtotle ſays, that his epipetron grows on rocky places, and continues to grow after it is taken up, as the orpin and ſome other plants will do.

EPIPHÆNOMENA, of επι and Φαινομενον, *ſymptom*, in the *Writings of the Ancient Phyſicians*, a term uſed to expreſs ſuch of the ſymptoms, in certain diſeaſes, as did not uſually appear till the time that the diſeaſe was actually formed, called alſo epiginomena.

EPIPHALLUS, in the *Ancient Muſic.* It appears by a paſſage in Euſtathius, often quoted by Meurſius, that this was alſo the name of a dance, performed to flutes.

EPIPHAN, in *Geography*, a town and diſtrict of Ruſſia, in the government of Tula, ſituated on the Don.

EPIPHANES. See Epiphanius. This term in Greek, Επιφανης, denoted eminent or illuſtrious, and thus it was applied to Antiochus, which ſee.

Epiphanes, of επι and Φαινομαι, an epithet given to Jupiter, becauſe he manifeſted his preſence by lightning and thunder, &c.

EPIPHANIA, a word uſed, by ſome of the ancient phyſicians, to expreſs the external habit of the body.

Epiphania, in *Ancient Geography*, a town of Aſia Minor, in Cilicia, near the Mediterranean, between the branches of mount Amanus, on the river Carſus; probably denominated Epiphania in honour of Antiochus Epiphanes, king of Syria, who poſſeſſed Cilicia. We learn from Tacitus, that the part in Cilicia, in which this town was ſituated, became ſubject to the dominion of Rome under Lucullus, about the year of the city 683. It was afterwards epiſcopal under the metropolis of Anazarba.

Epiphania *on the Euphrates*, a town of Aſia, ſituated on that river.

Epiphania, a town of Syria, on the Orontes; which was ſubjected to the Romans about the year 690, during Pompey's expedition into the territory of Apamæa and into Coeleſyria. This town was ſituated between Lariſſa and Arethuſa; and it was reckoned by the Orientals one of the moſt ancient towns in the world, founded, as they imagined, by Hamath, one of the ſons of Canaan; and that its name was changed by the Macedonians in honour of Antiochus Epiphanes. (See Hamath.) It was epiſcopal under the metropolis of Apamæa.

Epiphania, a town of Aſia Minor, in Bithynia. Steph. Byz.—Alſo, a town of Aſia, on the banks of the Tigris, called by Steph. Byz. *Arſecicerta.*

EPIPHANIUS, or Epiphanes, in *Biography*, the ſon of Carpocras, or Carpocrates, an hereſiarch in the ſecond century, was inſtructed by his father in the whole circle of the ſciences, and particularly in the Platonic philoſophy; but his death, when he was 18 years of age, diſappointed the hopes which the Carpocratians entertained concerning him. After his death he was honoured by them as a god, particularly in the iſland of Cephalonia, where a temple was erected to him, with altars, a grove, and a muſæum, and where the day of his nativity was celebrated with hymns, libations, ſacrifices, and feaſtings. Theſe are the reports of Clement of Alexandria and of Epiphanius, unconfirmed by the teſtimony of other writers. Epiphanes is now claſſed with the Valentinians. Lardner Hiſt. Heret. c. iii. § 1.

Epiphanius, biſhop of Salamis in the iſland of Cyprus in the fourth century, and dignified by the Catholics with the title of Saint, was born in the vicinity of Eleutheropolis, in Paleſtine, about the year 320. In his youth he went into Egypt, where he inclined to the ſect of the Gnoſtics, but ſeparating from them, he joined himſelf to the Egyptian Aſcetics, imbibing their principles and conforming to their manners. In his 20th year he returned to his own country, and became a diſciple of Hilarion, the father of Paleſtine monkery. After ſome time he founded a monaſtery at Bezanduce, the village in which he was born, over which he preſided for the greateſt part of his life. In 367 or 368, he was appointed biſhop of Salamis, afterwards called Conſtantia, where his piety and ſanctity were held in high eſtimation, and where he was aſſiduouſly employed in writing defences of the orthodox doctrines againſt the attacks of heretics. His zeal, however, involved him in many troubles, which embittered a conſiderable portion of his life. One of the principal circumſtances which contributed to embarraſs and embroil him, and to entail diſgrace on his memory, was his inveterate oppoſition to the opinions of Origen. This produced a conteſt with John biſhop of Jeruſalem, who favoured theſe opinions, which, after many mutual invectives and recriminations, terminated in a breach between the two biſhops, that convulſed the eaſtern churches by the hatred and perſecuting ſpirit manifeſted in the conduct of their reſpective partiſans. Theophilus, biſhop of Alexandria, was an active adherent to the cauſe of Epiphanius, and held a council in 399, which condemned the writings of Origen, and prohibited all perſons from reading them, or having them in their poſſeſſion. This example was followed by a council of the biſhops of Cyprus, ſummoned by Epiphanius himſelf in the year 401. Failing of ſucceſs by the decrees of theſe councils and by the perſecution againſt Origen, which they were the means of inſtigating, the determined and zealous prelate took a voyage to Conſtantinople, in order to induce the biſhops in that city to adopt and ſanction the decrees of Alexandria and Cyprus. On his arrival, he declined holding any intercourſe with Chryſoſtom, biſhop of that city, unleſs he joined in the condemnation of Origen, and in withdrawing his protection from the exiled Egyptian monks. Exaſperated by the diſappointment of his views, he reſolved to preſent himſelf to the people in the church of the Apoſtles, and openly to condemn the books of Origen, and all his advocates. But before he could execute his purpoſe, he was warned of the irregularity of his proceedings, and of the ſedition which they might occaſion; and he, therefore, thought it moſt prudent to abandon his deſign. His next attempt was that of intereſting the court in his favour; and ſo violent and implacable was his zeal againſt thoſe who favoured Origen, that when the empreſs Eudoxia beſought his prayers in behalf of the younger Theodoſius, who was dangerouſly ill, he aſſured her that he ſhould not die, if ſhe would conſent to diſcard the heretics, who were ſheltered under the imperial patronage. The princeſs very properly reproved this arrogant and impious meſſage; and his impetuoſity was alſo checked by the Egyptian monks, who convicted him of being unacquainted with the principles of the perſons, againſt whom he had been induſtriouſly exciting univerſal indignation. Thus foiled and abaſhed, he ſet out on his return to Cyprus, and died either on his voyage, or ſoon after his return, in the year 402 or 403, at a very advanced age. The piety of Epiphanius was unqueſtionable; but it was blended with a gloomy ſuperſtition, which led him to promote the auſtere diſcipline of the cloiſter, and to employ his epiſcopal influence in multiplying monaſtic inſtitutions. In offices of charity for the relief of the indigent, he expended not only his own private fortune, but the greateſt part of the revenues of his church, and large ſums entruſted to his diſpoſal. His learning was conſiderable, for, according to St. Jerome, who mentions him in terms of high commendation, and calls him πενταγλωττος, a man of five languages, he underſtood Greek, Syriac, Hebrew, Egyptian, and partly Latin. It is allowed, however, that he was deficient in judgment, and unſkilful in wielding the weapons of controverſy. Careleſs in his tranſcripts from ancient authors, and credulous in admitting unauthenticated reports, he has been betrayed into various contradictions and abſurdities, ſo that his works, with reſpect to authority and reference, are depreciated in value. His ſtyle is mean, harſh, and unpoliſhed, without perſpicuity, and without connection. In his remaining works he has given ſeveral catalogues of the books of the Old and New Teſtament. His canon of the Old Teſtament was much the ſame with that of the Jews. (See Canon.) The books of the New Teſtament received by him are the ſame with thoſe generally received by us. For both theſe claſſes of ſacred books he profeſſes the higheſt regard; nor does he ever make uſe of Chriſtian apocryphal books, written in the name of apoſtles and falſely aſcribed to them. With reſpect to the books of the New Teſtament, he ſays, that Matthew preached, and wrote his goſpel in Hebrew, and that he was the only writer of the New Teſtament who uſed this language. He had heard, however, that the goſpel of St. John, and the Acts of the Apoſtles, had been tranſlated from Greek into Hebrew, and were in the library of the Jews at Tiberias. Matthew wrote firſt, and ſoon after Mark, who was Peter's companion at Rome. The third goſpel, in his enumeration, was that of Luke. John wrote his goſpel at the age of 90 years, and Epiphanius ſays, that it was occaſioned by the errors of the Ebionites, the Cerinthians, the Merinthians, and Nazarenes. He aſcribes the book of the Acts to Luke. He frequently quotes the epiſtle to the Hebrews as Paul's; he alſo cites the epiſtle of James, the two epiſtles of Peter, John's firſt and ſecond epiſtles, and the Catholic epiſtle of Jude. He alſo received the book of Revelation. Of the baptiſm of Chriſt, he ſays, that it took place when he was 29 years and 10 months, thus underſtanding St. Luke's words, iii. 23. He ſays, there are two paſſovers in our Lord's miniſtry, according to St. John's goſpel, and that he ſuffered at the third paſſover, in the 33d year of his life on earth; and therefore he did not think the "feaſt of the Jews," mentioned John, v. 1. to be a paſſover. He ſays, that the apoſtles did not preach themſelves, but Jeſus Chriſt, Lord. Therefore there was no ſect, or church, called after the apoſtles; for we never heard of Petrians, or Paulians, or Bartholomeans, or Thaddeans, but of Chriſtians only; as they were called at Antioch. The works of Epiphanius were firſt printed in Greek at Baſil by Oporinus in 1544; and the ſubſequent impreſſions have been numerous, of which the moſt valuable is that publiſhed at Paris in 1622, in two volumes folio, by the learned Petavius, who gave a new Latin verſion, with critical notes and obſervations. This edition was afterwards printed at Cologne in 1682, in two volumes folio. Cave's H. L. vol. i. ſub ſæc. Arian. Lardner's Works, vol. iv.

Epiphanius, ſurnamed "The Scholaſtic;" a native of Italy, and an eminent Greek and Latin ſcholar, was born about the year 510. At the requeſt of Caſſiodorus he tranſlated into the Latin language the eccleſiaſtical hiſtories of Socrates, Sozomen, and Theodoret, a verſion more entitled to commendation for its fidelity than its elegance. Caſſiodorus was alſo indebted to Epiphanius for the improved verſion of the "Codex encyclicus," or collection of ſynodal letters of the year 458, addreſſed to the emperor Leo, in defence of the council of Chalcedon. Cave H. L. vol. i. ſub ſæc. Eutych.

Epiphanius, patriarch of Conſtantinople in the 6th century, ſtrenuouſly vindicated the orthodox doctrines againſt the Eutychians, and after elevation to his dignity in the year 520, procured the condemnation of the latter in a ſynod of biſhops held at Conſtantinople. Whilſt he was patriarch, the decrees of the council of Chalcedon were confirmed, and a reconciliation was completed between the churches of Conſtantinople and Rome, after a ſchiſm which laſted 35 years. Five letters of this patriarch to pope Hormiſdas on the ſubject of the union are extant in the 4th volume of the collection of the Latin councils. Cave H. L. vol. i. ſub ſæc. Eutych.

EPIPHANY, in *Eccleſiaſtical Antiquity*, the feaſt of kings; a double feſtival, of the firſt rank, ſolemnized on the ſixth of January, commonly called "Twelfth day," in honour of the appearance of Jeſus Chriſt to the three kings, or magi, who came to adore, and bring him preſents.

The feaſt of Epiphany, now held in honour of the adoration of the magi, had its firſt inſtitution among the Greeks, from a different object, *viz.* our Saviour's birth; and was called theophany, and epiphany, that is, appearance, and manifeſtation, of God.

Pope Julius, who reigned from the year 337 to 352, was the firſt who taught the church to diſtinguiſh the feaſts of the nativity and epiphany. Papebroch. Paral. ad Conat. p. 23. Act. SS. Maii, tom. vii.

The word in the original Greek, επιφανεια, ſignifies *appearance*, or *apparition*; and was applied, as ſome critics will have it, to this feaſt, on account of the ſtar which appeared to the Magi. St. Jerom and St. Chryſoſtom, take the Epiphany for the day of our Saviour's baptiſm, when he was declared to men by the voice, "Hic eſt Filius meus dilectus, in quo mihi complacui: This is my beloved Son, in whom I am well pleaſed." And accordingly it is ſtill obſerved by the Cophtæ and Ethiopians in that view. (See Ludolph. Hiſt. Æthiop. lib. xxi. cap. 2.) Others contend, that the feaſt of Chriſtmas, or the nativity of our Saviour, was held in diverſe churches on this day; which had the denomination Epiphany, or appearance, becauſe of our Saviour's firſt appearance on earth, as at that time. And it muſt be allowed, that the word is uſed among the ancient Greek fathers, not for the appearance of the ſtar to the magi, but for that of our Saviour to the world. In which ſenſe, St. Paul uſed the word επιφανεια, *epiphania*, in his ſecond epiſtle to Timothy, chap. i. ver. 10. Ammianus Marcellinus makes mention of this feaſt, lib. xxi. cap. 2.

and obſerves, that it was held in January. Upon which paſſage Valeſius, in his notes, endeavours to ſhew, that the hiſtorian meant by Epiphany the feaſt of the nativity.

The heathen writers uſed the word epiphania in the like ſenſe, *viz.* to expreſs the appearance of their gods on earth. And the Chriſtians, after their example, applied it, in the general, to expreſs any appearance, or manifeſtation of the Deity.

EPIPHEOS, in *Botany*, the name given by the ancients to the dodder, or cuſcuta, which grew upon the ſhrub they called phæos. This was the ſtæbe of the modern Greeks, deſcribed by Honorius Bellus. It was a cuſtom, among the old writers, to name the cuſcuta, or dodder, from the plant it was found growing upon, as they ſuppoſed that it in ſome degree partook of the virtues of that plant. Thus that which grew upon thyme was called epithymum, and that upon the nettle, epiurteca, and that upon flax, epilinum; ſo of many others.

The ſhrub phæos was alſo called ſtæbe by Dioſcorides and Theophraſtus; and hence this dodder was ſometimes called epiſtæbe.

EPIPHLEBOS, of επι and φλεψ, *a vein*, in the *Writings of the Old Phyſicians*, a term uſed to denote ſuch perſons as were lean, and of a hot temperament, and whoſe veins, for that reaſon, appeared uſually very turgid and prominent in the hands, &c.

EPIPHLOGISMA, (from επι, and φλογιζω, *to inflame*,) in *Surgery*, a violent inflammation, accompanied with pain, ſwelling, and redneſs. Alſo, a great internal heat: likewiſe, the affection uſually called eryſipelas.

EPIPHONEMA, Επιφωνημα, *Acclamation*, in *Rhetoric*, a ſententious ſort of exclamation, which is frequently added after a narrative, or rehearſal of any thing remarkable; containing uſually a lively, cloſe reflexion on the ſubject there ſpoken of and intended to give it greater force, and render it more affecting to the hearers.

Such is that of St. Paul, when, after diſcourſing of the rejection of the Jews, and the vocation of the Gentiles, cries out,

"O the depth of the wiſdom and knowledge of God!"

Such alſo is that of Lucretius, after relating the ſtory of Agamemnon's ſacrificing his daughter Iphigenia:

"Tantum religio potuit ſuadere malorum."

This figure is frequently expreſſed in a way of admiration. Such is that of Cicero, when after having obſerved, that all men are deſirous of living to an advanced age, but uneaſy under it when attained, he makes this juſt reflection upon their conduct: "So great is their inconſtancy, folly, and perverſeneſs!" (Cic. de Senect. c. 2.)

The epiphonema is uſually expreſſive of the milder and more gentle paſſions, and is not ſo vehement and impetuous as exclamation.

EPIPHORA, (from επιφερω, *to carry with force*,) in *Surgery*. The original import of the word "epiphora" ſeems to have been a violent determination of fluids to any part of the body. At preſent, however, all ſurgeons confine the meaning of the term to an affection, in which the tears, not being able to paſs in a proper manner down into the noſe, accumulate in front of the eye, and trickle over the cheek. The diſorder is alſo not unfrequently denominated the "watery eye."

Whoever is in the habit of conſulting ſurgical books, will ſoon perceive, that writers do not make a clear diſtinction between the epiphora, and ſome ſtates of the fiſtula lachrymalis. Thus Mr. Ware has particularly conſidered the ſpecies of epiphora, which, he ſays, "is produced by an obſtruction to the free paſſage of the tears from the eye into the noſe. This obſtruction (he adds) may take place either in the ducts leading from the puncta lachrymalia into the lachrymal ſac, or in the ſac itſelf. When the ducts are obſtructed, a caſe which rarely occurs, the tears fall over the cheek, and the ſac is conſtantly empty. Preſſure on the ſac, therefore, can produce no regurgitation, either of tears, or mucus, into the eye. The method of cure is here evident. A ſmall probe of a ſuitable ſize muſt be introduced through the puncta of the obſtructed ducts into the ſac, and this operation be daily repeated until the obſtruction be removed. But, (continues Mr. Ware,) the part in which the obſtruction more commonly lies, is in the ſac itſelf; and in this caſe, the tears, mixed ſometimes with mucus, flow back into the eye through the puncta, when preſſure is made on the ſac." Now, this latter kind of diſeaſe, Pott, Scarpa, and other diſtinguiſhed ſurgical authors, conſider only as one ſtage of the fiſtula lachrymalis.

We do not mean, however, by what has been ſtated, to make any attempt to defend the manner in which the expreſſion "fiſtula lachrymalis" is employed; our ſole aim is to ſhew, that, unleſs a line of diſtinction is drawn between what ſhould be called "epiphora," and what "fiſtula lachrymalis," the comprehenſion of the ſubject is rather embarraſſed, than promoted, by having two different terms, which ſo glaringly encroach upon each other in the extent of their ſignification. The epiphora, in the meaning of a mere weeping of the eye, may ariſe from a variety of cauſes, which muſt be removed, ere the complaint can be cured. An encanthis, or any other kind of tumour in the inner angle of the eye, a polypus in the noſe, an ectropium, a trichiaſis, &c. may obſtruct the due flowing of the tears into the noſe, and thus make them fall over the ſubjacent cheek, ſo as to occaſion an epiphora. This latter diſorder may alſo be the conſequence of a part of the caruncula lachrymalis having been loſt, either by diſeaſe, or an unſkilful employment of the knife in ſome previous operation. An epiphora is always attendant on obſtructions in the ductus naſalis. Mr. Ware obſerves, with regard to another ſpecies of epiphora, originating from a too copious ſecretion of tears, that, if it does not depend on an affection of the mind, its more remote cauſe is uſually an inflammation of the eye. In this inſtance, a cure is to be effected by ſubduing the ophthalmy, and afterwards ſtrengthening the eye by mild aſtringent applications, ſuch as cold water, either alone, or containing a ſmall quantity of the zincum vitriolatum.

When the membrane, which lines the lachrymal ſac, is in a morbid ſtate, the mucus which it ſecretes is often ſo thickened, that it becomes incapable of paſſing through the ſac, and lodging in this ſituation, prevents the natural and regular deſcent of the tears from the eye into the cavity of the noſe.

This ſpecies of epiphora has occaſionally been benefited by the unguentum hydrargyri nitrati, applied to the edges of the eye-lids, and rubbed into the ſkin over the lachrymal ſac. Relief is alſo alleged to have been derived from the uſe of ſtimulating applications to the inſide of the noſe, which applications are ſuppoſed to have acted by increaſing the ſecretion from the pituitary membrane.

However, we muſt confeſs, that no men of experience, at the preſent day, place ſufficient reliance on the preceding methods, to recommend them to be tried by their patients. At the ſame time it ſhould be underſtood, that theſe plans are ſometimes exceedingly proper to be adopted in conjunction with other more efficacious meaſures.

In the year 1712, M. Anel recommended the introduction of a probe, and then the injection of a fluid, through the puncta lachrymalia, with a view of clearing away whatever matter might prevent the tears from readily finding their way through the lachrymal ſac and naſal duct into the noſe. M. Anel relates, that he accompliſhed many ſtriking cures in this manner; and Heiſter confirms the efficacy of the plan, by appealing to his own practice, in which he had often produced a complete recovery in the ſhort ſpace of three days.

In the year 1780, ſir William Blizard conſidered, that when water was injected through the punctum lachrymale, it not only had but very little ſpecific weight, but was driven through the lachrymal ſac in an unfavourable direction. Theſe reflections led him to make the propoſal of introducing quickſilver through a ſmall pipe, which communicated with a long tube full of this metal. Sir William Blizard was of opinion, that the quickſilver, in conſequence of its great weight, would have more power when the ſac was filled with it, of removing the obſtruction, than the mere injection of water. This gentleman alſo, in a paper read to the Royal Society, ſtates, that he had produced a cure by the introduction of quickſilver in an example which had laſted ſeven months; and that the mercury paſſed readily through the ductus naſalis, at the third and fourth times of repeating the operation.

When the celebrated Mr. Ware was in Paris, in the year 1791, he learnt from Meſſieurs Grandjean and Monſieur Arrachart, eminent oculiſts in that city, that the plan of injecting water through the puncta lachrymalia, in incipient caſes of fiſtula lachrymalis, was not given up in France. Mr. Ware even ſaw ſome troubleſome caſes cured on the continent in this way. Hence he was determined, on his return to London, to give Anel's operation a fuller trial than he had previouſly done. For this purpoſe he got Mr. Pepys, in the Poultry, to conſtruct a ſmall ſilver ſyringe, with pipes of different ſizes adapted to it.

The following caſe, which afforded Mr. Ware the firſt opportunity of aſcertaining more carefully the efficacy of Anel's treatment, is related in his own words, and will ſerve to inform the reader of ſeveral uſeful practical circumſtances.

" A lady in Great Ruſſel-ſtreet came under my care, who for many months had been ſubject to an epiphora of the left eye, which prevented her both from reading and working with her needle, without undergoing great inconvenience. Whenever ſhe employed herſelf in any way that required cloſe attention, her eye became overſpread with tears, and the ſight was ſo much confuſed, that it obliged her to leave off almoſt as ſoon as ſhe began. A great variety of remedies had been applied, under the direction of different medical men, but none of them produced any eſſential amendment. On examining the eye, I obſerved that the tunica conjunctiva, near the inner angle of the eye-lids, was ſlightly inflamed; and on preſſing the lachrymal ſac with my finger, I perceived that a tear regurgitated through the lower punctum. This appearing to be a proper caſe for the uſe of the ſyringe, I immediately determined to employ it. But I found, that though a tear came through the lower punctum on my preſſing the ſac, yet this punctum was ſo ſmall that it would not admit the point of the ſmalleſt ſyringe I then had. I introduced into it, however, a ſmall probe, and by means of this I ſo far dilated the orifice, that it admitted the point of the ſyringe on the next day without any difficulty. Upon my firſt uſing the injection, the water eſcaped through the upper punctum almoſt as faſt as it was introduced through the lower; but, notwithſtanding this, I perſevered in urging the liquor on, until the whole contents of the ſyringe were exhauſted. I repeated the injection three times the ſame day in immediate ſucceſſion. The lady, however, was not ſenſible that any part of the water paſſed through the duct into the noſe during either of theſe operations; and indeed it ſoon became evident that none had paſſed; for, having cleared her noſe before I began, on her blowing it again immediately afterwards, ſhe could produce no moiſture on her handkerchief. I repeated the operation three times, both on the ſecond and on the third day; and each day, during the time that the water was paſſing, I not only endeavoured to prevent it from coming through the upper punctum, by covering it with the point of my finger, but I occaſionally preſſed the lachrymal ſac in order to give the water an inclination downward. On the fourth day I very plainly perceived, on the patient's clearing her noſe after the operation, that a part of the water had paſſed through the duct; and, the next morning, I had the ſatisfaction to hear, that the eye, on the preceding day, had watered much leſs frequently than it had done for a conſiderable time previous to it. I repeated the proceſs above-mentioned about ten times, in as many days, and I obſerved that the quantity of water which paſſed through the duct was augmented every time I uſed it. The tears, after this, reſuming their natural courſe, the lady recovered the power to read and work without any inconvenience." (See Ware on the Epiphora.)

Mr. Ware, in his practice, uſes common water for the injection, ſometimes in a cold ſtate, but more frequently warmed. The pipes which this gentleman employs, are alſo much ſhorter than the one repreſented by Mr. Benjamin Bell in his Syſtem of Surgery, (vol. iii. pl. 37). They are alſo a little arched towards their point. Mr. Ware thinks, that when they are made in this manner, they can be more conveniently introduced into the punctum lachrymale, than when long and ſtraight. He recommends always having ready ſeveral pipes of different ſizes, and uſing the largeſt one which can be introduced without pain. He finds it alſo advantageous to ſtand either behind the patient or on the ſide oppoſite to that of the diſeaſed eye; and high enough to have a full command of the patient's head. Thus the operator will gain a complete view of the lower punctum, which will alſo be in a convenient poſition to receive the pipe of the ſyringe. Mr. Ware, moreover, adviſes us to remove the finger from the lower eye-lid as ſoon as the pipe is introduced, and to place it over the upper punctum, ſo as to prevent the fluid from eſcaping through this aperture. The ſame finger is likewiſe to be occaſionally uſed in making preſſure on the lachrymal ſac, in order to aid in forcing the injection down into the noſe.

Mr. Ware has publiſhed ſome additional remarks on the epiphora, and makes ſome very valuable obſervations on the treatment of another ſpecies of the diſorder; we allude to that kind which proceeds from a thickening of the membrane which lines the lachrymal ſac and duct, and a ſpaſmodic conſtriction in any part of this paſſage, conjoined, perhaps, with a morbid ſecretion of thickened mucus. Mr. Ware imputes a few occaſional failures, in the above ſimple mode of treatment, to the cauſes of the diſeaſe being ſometimes of this nature. The following extract will explain the different methods to which this celebrated oculiſt has recourſe in different caſes.

" I in general begin the treatment by injecting ſome warm water through the inferior punctum lachrymale, and I repeat the operation four or five days in ſucceſſion. If, in this ſpace of time, none of the water paſs through the duct into the noſe, and if the watering of the eye continue as troubleſome as it was before the injection was employed, I uſually open the angular vein, or direct a leech to be applied near the lachrymal ſac; adding here a caution, that the leech be not ſuffered to fix on either of the eye-lids, leſt it produce an extravaſation of blood in the adjacent cells. About the ſame time that blood is taken away in the neighbourhood of the eye, I uſually vary the injection, and try the effects either of a weak vitriolic, or anodyne, lotion. In ſome inſtances alſo, when I have found it impoſſible, after ſeveral attempts, to inject any part of the liquid through the duct, I have introduced a golden probe, about the ſize of a briſtle, through the ſuperior punctum lachrymale, and, attending to the direction of the duct, have inſinuated its extremity through the obſtruction, and conveyed it fully into the noſe; immediately after which I have found, that a liquid, injected through the inferior punctum, has paſſed without any difficulty; and, by repeating theſe operations, for a few ſucceſſive days, I have at length eſtabliſhed the freedom of the paſſage, and completed the cure. In other inſtances, I have recommended a ſtrongly ſtimulative ſternutatory to be ſnuffed up the noſe, about an hour before the time of the patient's going to reſt, which, by exciting a large diſcharge from the ſchneiderian membrane, has ſometimes alſo greatly contributed to open the obſtruction in the naſal duct.

"Caſes occur very rarely which may not be relieved by ſome of the means above related." (Ware's Additional Remarks on the Epiphora.)

When the diſcharge has been fetid, Mr. Ware has ſometimes found, that a vitriolic lotion, injected into the ſac, has quickly corrected the quality of the matter.

Scarpa, in his "Oſſervazioni ſulle principali Malattie degli Occhi," maintains, that the chief part of the yellow viſcid matter, which accumulates in the lachrymal ſac, is ſecreted by the lining of the eye-lids, and by the little glands of Meibomius; and that the altered quality of this ſecretion has a principal ſhare in the cauſe of the diſeaſe. He ſtates, that the truth of this fact may at once be aſcertained by everting the eye-lids; and eſpecially the lower one of the affected ſide; and by comparing them with thoſe of the oppoſite eye. The former will always exhibit an unnatural redneſs of the internal membrane, which has a villous appearance, all along the extent of the tarſus, while their edges are ſwollen; and numerous varicoſe veſſels are diſtinguiſhable on its ſurface. The follicles of Meibomius are alſo turgid and prominent.

Hence, Scarpa adviſes making ſuch applications to the inſide of the eye-lids, as have a tendency to improve the quality of the ſecretion from them, at the ſame time, that attempts are made to remove the obſtruction in the ductus naſalis. Mr. Ware, indeed, had previouſly noticed, that ſuch treatment may occaſionally be proper.

"When an epiphora is occcaſioned by an acrimonious diſcharge from the ſebaceous glands on the edges of the eye-lids, it muſt be evident, that injections into the ſac will be very inſufficient to accompliſh a cure, becauſe the ſac is not the ſeat of the diſorder. The remedies that are employed muſt be directed, on the contrary, to the ciliary glands themſelves, in order to correct the morbid ſecretion that is made by them; and for this purpoſe, I do not know any application that is ſo likely to prove effectual as the unguentum hydrargyri nitrati of the new London Diſpenſatory, which ſhould be uſed here in the ſame manner in which it is applied in common caſes of the pſorophthalmy. It will be proper to cleanſe the eye-lids every morning, from the gum that collects on the edge during the night, with ſome ſoft unctuous application; and I uſually adviſe to apply to them two or three times in the courſe of the day a lotion compoſed of three grains of white vitriol, in two ounces of roſe, or elder-flower, water."

Mr. Ware very judiciouſly cenſures the plan of applying collyria to the eye by means of linen, wet in them; and he recommends eye-glaſſes for the purpoſe, or inſinuating the fluid, between the eye and eye lids, with a camel-hair pencil, thoroughly wet in the application. (Additional Remarks on the Epiphora.)

Scarpa alſo extols waſhing the eye, three or four times a day, with a vitriolic collyrium; and, beſides praiſing the ointment recommended by Mr. Ware, he recommends Janin's ophthalmic ointment, to be ſmeared over the margins and lining of the eye-lids every morning and evening.

℞. *Adipis Suillæ. Tutiæ præp. Bol. Armen. ſing.* ʒij. *Calcis Hydrarg. alb.* ʒj. *Miſce.* To be uſed at firſt lowered with a larger proportion of lard, than is above ordered. See Fistula *Lachrymalis.*

EPIPHYLLOSPERMOUS Plants, of επι, φυλλον, *leaf*, and σϖερμα, *ſeed*, are the ſame with the capillaries, herbs which bear their ſeed on the back part of their leaves. See Capillary.

EPIPHYLLUM, in *Botany*, επι, *upon*, and φυλλον, *a leaf*, from the mode in which the flowers grow upon a flat ſtem reſembling a leaf, ſee Cactus *Phyllanthus*, ſp. 40.

EPIPHYSIS, in *Anatomy*, is a name given to certain parts of bones at a particular period of their formation. See Bone.

EPIPLA'SMA, from επι, and ϖλασσῶ, *to ſpread*, in *Surgery*, the name of an application to wounds: it conſiſted of wheat meal boiled in hydrelæum.

EPIPLOCE, Επιπλοκη, in *Rhetoric*, the ſame with climax, which ſee.

EPIPLOCE'LE, from επιπλοον, *the omentum*, and κηλη, *a tumour*, in *Surgery*, an omental hernia, or a rupture formed by a protruſion of a piece of omentum from the cavity of the abdomen.

Le Dran informs us, that in an epiplocele there is nothing to be felt, except a doughy ſoftneſs, which neither abſolutely yields to the touch, nor very ſenſibly reſiſts it. The tumour has a flabby unequal feel; and, when there is no ſtricture, is perfectly indolent. It is more compreſſible than that ariſing from protruded inteſtine, and, when the quantity of omentum is large, the epiplocele may, in ſome meaſure, be diſtinguiſhed by its weight.

As the ſubject of omental ruptures will be particularly conſidered under the head Hernia, we ſhall, for the preſent, content ourſelves with referring to the latter article.

EPIPLOIC, in *Anatomy*, a term applied to parts which belong to the epiploon, or omentum; thus we have epiploic arteries, &c.

EPIPLOO'MPHALON, from επιπλοον, *the omentum*, and ομφαλος, *the navel*, in *Surgery*, an omental hernia protruding at the navel.

EPIPLOON, in *Anatomy*, called alſo omentum or cawl, is a membranous expanſion contained in the cavity of the abdomen: and continued from the peritoneal covering of ſome of the viſcera. There are two very diſtinct productions, of the nature juſt deſcribed, diſtinguiſhed by the appellations of minus and majus, from their difference in ſize; and by thoſe of hepatico-gaſtricum, and colico-gaſtricum from their ſituation. But when the epiploon, or omentum, is ſpoken of generally, the greater or colico-gaſtric portion is underſtood. To the peritoneal ſurface of the large inteſtine are attached numerous ſmall proceſſes, which reſemble the epiploa in their apparent ſtructure, and are called *appendices epiploicæ*.

Although the omenta are uſually repreſented by anatomiſts as proceſſes of the peritoneum, their organization differs eſſentially from the ſtructure of that membrane. Their groundwork or baſis conſiſts of the moſt delicate and tranſparent membrane of the body; which is lacerated on the application of very ſlight force. This membrane is compoſed obviouſly of two layers, connected by cellular tiſſue, and containing numerous venous and arterial ramifications. A greater or ſmaller quantity of fat is depoſited between theſe layers, and in the courſe of the veſſels. When this depoſition is very conſiderable, as in very corpulent individuals, or in animals who have been fattened for the ſlaughter, the peculiarly tranſparent delicate appearance of the omental membrane is entirely deſtroyed, and the part is converted into a layer of fat. Ordinarily, however, the adipous ſubſtance is confined to the neighbourhood of the blood-veſſels, accompanying them in their ſubdiviſions, but leaving intervals in which the membrane exhibits its diſtinguiſhing diaphanous appearance. In emaciated ſubjects, during the period of infancy, and particularly in the fœtal ſtate, the quantity of fat is very trifling. Under ſuch circumſtances we can obſerve moſt diſtinctly that the depoſition of fat is confined to the courſe of the veſſels. As the omenta are entirely unconnected to the parts on which they lie, as well as to thoſe by which they are covered, both their ſurfaces are ſmooth and gliſtening, and moiſtened like thoſe of other ſerous membranes, by a ſerous exhalation, which facilitates their motions over the neighbouring organs. Analogy warrants us in aſcribing this ſecretion to the arteries of the omenta; and we conſequently conſider theſe organs as an extenſion of the general ſerous ſurface of the abdominal cavity.

Experiments on living animals, and ſurgical operations, clearly prove that the membrane of the omenta poſſeſſes little, if any, ſenſibility in its healthy ſtate.

The *leſſer epiploon*, *meſogaſter*, *omentum minus*, or *hepatico-gaſtricum*, is the portion extended from the ſmall arch of the ſtomach to the concave or under ſurface of the liver. It ariſes, behind, from the poſterior half of the tranſverſe fiſſure of the liver; on the right it is continuous with the peritoneum covering the neck of the gall-bladder and the beginning of the duodenum; towards the left it is reflected immediately from the diaphragm. Advancing from theſe points, in two cloſely united layers, towards the ſtomach, it is attached to the end of the œſophagus, to the whole leſſer arch of the ſtomach, to the pylorus, and commencement of the duodenum. At this line its layers divide, and expand over the ſtomach, one of them forming the ſuperior, and the other the inferior peritoneal covering of this viſcus. Between the layers of the leſſer omentum are contained the hepatic veſſels and biliary ducts, the coronary veſſels of the ſtomach, ſome branches of the cœliac plexus of nerves, and of the par vagum, and a few abſorbent glands. Fat is rarely depoſited here in ſo large a quantity as in the large epiploon, ſo that we can uſually ſee through it that portion of the liver called lobulus ſpigelii, which is in contact with its inferior ſurface.

The biliary ducts, the hepatic veſſels with numerous accompanying branches of nerves from the cœliac ganglia, and a conſiderable portion of the hepatic and cyſtic abſorbents, connected and ſurrounded by adipous and cellular ſubſtance, are incloſed in the right edge of the leſſer omentum. This part is called *capſula Gliſſoni*, from an Engliſh anatomiſt, who deſcribed it minutely in a work entitled "De Hepate." The very margin of the omentum is occupied by the biliary ducts, and the neck of the gall-bladder. At this border the two ſurfaces of the little omentum are continuous. Behind the unconnected edge, round which the peritoneum turns, is found the foramen of Winſlow, or *foramen epiploicum*, large enough to admit one or two fingers, which can thus be placed in immediate contact with the back part of the liver, and the inferior ſurface of the little omentum. This opening is ſituated between the neck of the gall-bladder, and the beginning of the duodenum, with the hepatic veſſels in front, and the vena cava behind. It is not unuſual to find its edges adhering together. We ſhall have occaſion to mention it again after deſcribing the large omentum.

The great omentum, *epiploon majus*, *vel gaſtro-colicum*, is the looſe membrane, more or leſs loaded with fat, lying in front of the bowels, and generally meeting our eye in laying open the abdomen. It differs extremely in length and ſituation; in ſome caſes reaching as low as the pelvis, and often deſcending in ruptures to the very bottom of the ſcrotum; while in others it extends but a ſhort way below the umbilicus. It is always ſhorter in children than in adults. We often find it folded, or rolled on itſelf, and drawn to ſome one part of the abdomen, or tucked up over the ſtomach, ſo as to leave the ſmall inteſtines expoſed to our immediate view. Its natural ſituation between the bowels, and the parietes of the abdomen, explains the frequency of its protruſion, together with the inteſtines, in herniæ. Some anatomiſts aſſert that it hangs lower on the left than on the right ſide of the abdomen.

The great omentum is a continuation of the peritoneal covering of the ſtomach. We have already deſcribed this as being formed by the ſeparation of the two layers which conſtitute the little omentum. At the great curvature of the ſtomach theſe layers again coaleſce into one ſheet of membrane, are produced till they meet with the tranſverſe arch of the colon, to incloſe which they again ſeparate. Meeting at the oppoſite line they once more unite, and are continued under the name of the tranſverſe meſocolon to the root of the meſentery. The origin of the great epiploon, when minutely examined, commences in the left from the end of the œſophagus, and from the notch of the ſpleen (where it forms a membranous connection between this organ and the ſtomach) and includes the whole of the great arch of the ſtomach nearly as far as the pyloris. The portion of membrane thus formed deſcends looſely before the tranſverſe arch of the colon, and reaches to different lengths beyond it, conſtituting the anterior layer, or *lamina gaſtrica* of the great epiploon. At the lower or floating border this membranous expanſion is doubled on itſelf, and turning upwards again to meet the tranſverſe arch of the colon, forms the poſterior layer, or *lamina colica* of Haller. On the right ſide the great omentum is not only attached to the tranſverſe portion of this inteſtine, but is continued along its hepatic flexure, and for ſome way down the aſcending colon. In ſome inſtances it reaches as low as the cœcum. It is this lateral extenſion of the great omentum which conſtitutes the *omentum colicum* of Haller. Each of the layers is compoſed of a duplicature of peritoneum, as we have before ſtated, containing its proper veſſels, and fat, and united cloſely by cellular tiſſue. It will be evident, from our deſcription, that the great omentum is formed by the anterior layer alone in the ſpace between the ſtomach and tranſverſe arch of the colon; below the latter it is compoſed of the two layers, the lamina gaſtrica, and the lamina colica lying in contact with each other, but having no further connection in a healthy ſtate of the oppoſing ſurfaces.

From this diſpoſition of the great and little epiploa, there reſults, in conjunction with the inferior ſurface of the ſtomach, and the ſuperior ſurface of the tranſverſe meſocolon a membranous bag, called uſually the bag of the omentum. It offers every where on the inſide a continuous ſerous ſurface, where the ſides of the cavity are in cloſe contact, but not adherent. The communication between this pouch, and the general cavity of the peritoneum, is formed by the foramen of Winſlow. In order to demonſtrate this fact, as well as to diſplay the bag formed by the omenta, we introduce into this opening a pipe, ſurrounded by ſome ſoft ſubſtance, to prevent the eſcape of the air. By blowing gently we are enabled to ſeparate the layers of the great omentum, which were in contact, and give to the whole the form of a large membranous bag, interſected by veſſels and bands of fat, between which the membrane riſes in pouches of various ſizes. The lines formed by the ſtomach, and tranſverſe arch of the colon, are but faintly ſeen, owing to the diſtention of the epiploon, which appears, as it were, ſuſpended between them. To inſure the ſucceſs of this experiment ſome conditions are neceſſary, which we are not always happy enough to bring together. There muſt be no adheſion of ſurfaces, no large accumulation of fat, the ſubject young, and the whole conducted with the greateſt delicacy, as the ſlighteſt rent in the membrane is ſufficient to prevent ſucceſs. In the fœtus, and in young children, the laminæ of the great omentum are eaſily ſeparable throughout their whole extent. In adults, and more ſo in old perſons, they are generally more or leſs united, ſo that the cavity of the omenta is confined to the ſpace contained between the little omentum, the under ſurface of the ſtomach, and the tranſverſe meſocolon.

The arteries of the great omentum are derived from the right and left gaſtro-epiploic veſſels. They are in general ſmall, and deſcend between the layers of the lamina gaſtrica, giving off branches on either ſide, which anaſtomoſe freely in every direction. At the lower border of the omentum the trunks turn up again to meet the tranſverſe arch of the colon, with the arteries of which inteſtine they form communications. The veins accompany the arteries in their courſe, and join the large venous trunks which end in the vena portarum. The few nerves it poſſeſſes are derived from the hepatic, and ſplenic plexuſes.

The *appendices epiploicæ*, or *omentula*, are principally obſerved on the firſt parts of the great inteſtine, being in leſs number on the ſigmoid flexure of the colon and the rectum. They are irregularly diſpoſed, hanging in fringes, generally unconnected with each other, ſometimes united by intermediate membranous productions. They are uſually dependent from the pouches of the inteſtine, and not from the longitudinal bands. They are obviouſly formed by the peritoneal covering of the inteſtines, united by cellular membrane, and containing a depoſit of fat in almoſt every inſtance.

The uſe of the omenta is entirely unknown: The leſſer epiploon offers a covering, and connecting medium to ſome nerves belonging to the ſtomach, and to the hepatic veſſels and ducts. To the great epiploon many offices have been aſcribed, none of which are ſatisfactorily aſcertained. It varies ſomewhat in ſize according to the ſtate of the ſtomach; ſince, when the latter is diſtended, it appears to enter between the layers of peritoneum forming the anterior fold, which loſe in this caſe their form of omentum, and become the temporary covering of this organ. What may be the probable advantages of this conſtruction it is not eaſy to decide. It has been ſuppoſed again to ſecrete a lubricating fluid from its ſurface, which preſerves the free motion of all the chylopoietic viſcera between each other. That it increaſes the ſerous ſurface of the abdominal cavity is evident; but in what manner this becomes an advantageous diſpoſition is more than we have the means of determining. The omentum colicum, and appendices epiploicæ are ſubject to the ſame obſervations, being ſimilar in ſtructure, and conſequently in uſes. It is certain that a conſiderable portion of the great omentum may be cut away, without any ſubſequent inconvenience to the patient, as has been frequently obſerved in caſes of omental hernia.

An epiploon is found in all the mammalia, where it is ſeen under every variety of form and ſize; ſo that no inferences can be drawn from its diſpoſition in theſe particulars. In all it contains more or leſs of fat between its membranes, the accumulation of which would appear to bear ſome proportion to the active, or ſluggiſh habits of the animal. In the hybernating ſpecies during the winter, it is loaded with fat, which exiſts but in minute quantities during the ſummer. The epiploon is not found in the other claſſes of animals, at leaſt there is nothing analogous to it, but a membranous production between the liver and ſtomach, anſwering to the little omentum.

EPIPLO'SCHEOCE'LE, from επιπλοον, *the omentum*, οσχεον, *the ſcrotum*, and κηλη, *a tumour*, in *Surgery*, an omental rupture, ſituated in the ſcrotum.

EPIPOGUM, in *Botany*, επι, *upon* and πογον, a *beard*, becauſe the beard, or rather lip, is turned upwards. Gmel. Sib. v. 1. 11. t. 2. f. 2. is *Satyrium Epipogium* of Linnæus; *Limodorum Epipogium* of Swartz and Willdenow. See LIMODORUM.

EPIPOLÆ, in *Ancient Geography*, was originally a piece of high ground without the city of Syracuſe, and afterwards ſo little inhabited that it is not mentioned by Cicero in his deſcription of this city. As it was the moſt elevated ſituation, and commanded Tyche and Neapolis, it was judiciouſly incloſed by Dionyſius I., who encompaſſed it with a wall nearly 4 miles in extent. Its additional defence was the fortreſs of Labdalon, at its bottom, on the eaſt; and that of Euryalus, at its top, on the north. See SYRACUSE.

EPIPOMPEUTICA, in the *Ancient Muſic*. Voſſius, in his poetical inſtitutes, informs us, that this was a title given to ſongs compoſed and ſung on occaſions of great magnificence.

EPIPORO'MA, from επιπωροω, *to harden*, in *Surgery*, a hard tumour on a joint: a tophus.

EPIPROSLAMBANOMINOS, *Gr.* in the *Ancient Muſic*, a name given to the ſtring or ſound below proſlambanominos, which word correſponds with gamut in the Guido ſcale.

EPIRE, in *Geography*, an ancient kingdom of Greece, now united with Albania, and included in that country, of which it forms the ſouthern part, extending from Valona to Arta.

EPIROTS, in *Ancient Geography*. See the next article.

EPIRUS, a country of Greece, bounded on the eaſt by Ætolia, on the weſt by the Adriatic, on the north by Theſſaly and Macedon, and on the ſouth by the Ionian ſea. This was the ancient kingdom of the Æacidæ, and was firſt called "Epirus Dodonæa," *i. e.* the continent of the Dodonæans, and afterwards Epirus, or "the continent," that being the import of the Greek word Ηπειρος. It was anciently divided into three diſtricts or provinces; *viz.* Chaonia, Theſprotia, and Moloſſis; to which ſome authors add Caſſopia, Caſſiope, or Cæſtrine, and Pindus. This country is ſaid to have been firſt peopled by Dodanim, the ſon of Javan, and grandſon of Japhet, or at leaſt by ſome of his poſterity. We find among the nations which occupied Epirus, before they were united into one people under the common name of Epirots, the Selli, who are thought to have been the firſt inhabitants of Epirus, and to have miniſtered in the temple of Dodona, the Chaones, the Moloſſi, the Dolopes, the Dryopes, the Ænianes, the Pelaſgi, &c. The form of government which prevailed in Epirus was unqueſtionably monarchical, the whole country being divided into many ſmall independent kingdoms. Homer, and other ancient writers, mention ſeveral kings who reigned here at the time of the Trojan war. But while the other Epirotic nations continued to be governed by princes of their own blood, the Moloſſi became ſubject, at an early period, to the power of Pyrrhus, a foreign prince, whoſe deſcendants were denominated Æacidæ, from Æacus, the founder of his family. Some of theſe petty kingdoms, in proceſs of time, exchanged the monarchical into a republican form of government; for Thucydides informs us, that in his time the Theſprotæ and Chaones were governed, not by kings, but by annual magiſtrates. However, the kingdom of the Moloſſi ſoon eclipſed all others; the Moloſſian princes having ſubjected the whole country, and united the ſeveral ſmall kingdoms of which it conſiſted into one, known to the ancients under the name of Epirus.

Pyrrhus, the firſt of the Æacidæ, was the ſovereign of this country at the period when regular and authentic hiſtory commences; and he is ſaid to have diſtinguiſhed himſelf at the ſiege of Troy, when his father was killed. His reign ſoon terminated by a premature death; for he was murdered by Oreſtes in the temple of Delphi, on account of his having married Hermione, the daughter of Menelaus, who had been betrothed to Oreſtes. He was ſucceeded by his ſon Moloſſus, and ſeveral other princes, whoſe names it is needleſs to record. At length Admetus was the ſovereign of Epirus, when Xerxes invaded Greece. This prince, upon the defeat of the Perſians, wiſhed to enter into an alliance with the Athenians, about the year 478 or 479 B. C. The ſucceſſors of Admetus were Tharymbas, who is ſaid to have introduced the ſciences into this country, and to have formed an excellent code of laws; and Alcetes, at whoſe death the kingdom was divided between his two ſons, Neoptolemus and Arybas, the latter of whom, when his brother died, became ſole ſovereign of the country, and conducted the government with great prudence, equity, and moderation. He alſo encouraged literature by extending his patronage to thoſe who excelled in it. His niece Olympias, of whoſe education he had taken great care, was married to Philip, king of Macedon, who had by her Alexander the Great. At his death, he was ſucceeded by Alexander, one of his nephews; who is ſaid to have been little inferior, in courage and conduct, to his nephew Alexander the Great; but he had the misfortune to engage, on his firſt ſetting out, with nations inured to the toils of war, and no leſs brave than his own Epirots; whence he uſed to ſay, that the country, which he propoſed to conquer, was inhabited by men, whereas the provinces his nephew Alexander went to ſubdue, were peopled by women only. (Aul. Gell. l. xvii. c. 21.) The immediate ſucceſſors of Alexander were Æacides and Alcetes II.; and the latter was ſucceeded by Pyrrhus, deſcended by the father from Achilles, and from Hercules by the mother. (See Pyrrhus.) After two or three ſhort reigns, Deidamia, great grand-daughter to Pyrrhus, ſucceeded her father Pyrrhus III. and having no iſſue, ſhe gave the Epirots their liberty, who formed themſelves into a republic, which was governed by magiſtrates annually elected in a general aſſembly of the whole nation. The Macedonians on one ſide, and the Illyrians on the other, taking advantage of the inteſtine diviſions, which generally attend a popular government, ſeized on ſeveral provinces belonging to the Epirots, and annexed them to their reſpective crowns. The Romans, after having conquered Philip of Macedon, reſtored them to their ancient liberty; but they ungratefully took up arms againſt their benefactors, and joined Perſes; which induced the Romans to ſend orders to Paulus Æmilius, after the reduction of Macedon, to plunder their cities and level them with the ground. This order was punctually, though reluctantly, executed throughout the whole country in one day. One hundred and fifty thouſand of the inhabitants were made ſlaves, and ſold to the beſt bidder for the benefit of the republic. All the cities of Epirus, to the number of 70, were diſmantled, and the chief men of the country carried to Rome, where they were tried, and moſt of them condemned to perpetual impriſonment. After this cataſtrophe, Epirus never recovered its ancient ſplendour. Upon the diſſolution of the Achæan league, it was made part of the province of Macedon; but when Macedon became a dioceſe, Epirus was made a province of itſelf, called the province of Old Epirus, to diſtinguiſh it from New Epirus, another province lying to the eaſt of it. On the diviſion of the empire, it fell to the emperors of the eaſt, and continued under them till the capture of Conſtantinople by the Latins, when Michael Angelus, a prince nearly related to the Greek emperor, ſeized on Ætolia and Epirus. He was ſucceeded by his brother Theodorus, who ſo far enlarged his dominions, that, diſdaining the title of deſpot, he aſſumed that of emperor, and was crowned by Demetrius archbiſhop of Bulgaria. Charles, the laſt prince of this family, dying without lawful iſſue, bequeathed Epirus and Acarnania to his natural ſons, who were expelled by Amurath II. Great part of Epirus was afterwards held by the noble family of the Caſtriots, who, though they were maſters of all Albania, yet ſtyled themſelves princes of Epirus. Upon the death of the famous George Caſtriot, Epirus fell to the Venetians, who were ſoon diſpoſſeſſed of it by the Turks, in whoſe hands it ſtill continues; being now known by the name of Albania, which comprehends the Albania of the ancients, all Epirus, and that part of Dalmatia which is ſubject to the Turks. Plutarch tells us, that the Epirots enjoyed the beſt ſort of liberty under their kings; for, as he ſays, a general aſſembly of the people was annually convened at Paſſaron, a city in the province of Moloſſis, where the king bound himſelf by a ſolemn oath to govern agreeably to the laws, and the people to obey and ſupport him as long as he ſhould make the laws the rule of his government.

EPISARCIDIUM, from επι and σαρξ, *fleſh*, a name given by many of the old authors to an anaſarca.

EPISCAPHIA, from επι and σκαφη, *boat*, feaſts celebrated by the Rhodians.

EPISCENIA, from επι and σκηνη, *tent*, feaſts celebrated by the Lacedæmonians.

EPISCENIUM, Επισκηνιον, in *Antiquity*, a place upon the top of the theatre, where all the machines for moving the ſcenes were kept. Potter. Archæol. Græc. lib. i. cap. 8. p. 42.

EPISCEPSIS, Επισκηψις, an action brought to prove the diamartyria, or proteſtation, that the perſon deceaſed had left an heir, to be falſe and groundleſs. Potter. Archæol. Græc. lib. i. cap. 24. i. p. 128.

EPISCIRA, Επισκιρα, or Episcirosis, a feſtival celebrated at Scira in Attica, in honour of Ceres and Proſerpine. Potter. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 395.

EPISCHESES, from ἐπεχω, or ἐπισχω, *I reſtrain*, in *Medicine*, a term uſed by Dr. Cullen to denote the fifth order of his fourth claſs of diſeaſes, which includes the retention of accuſtomed evacuations, *viz.* conſtipation of the bowels, ſuppreſſion of urine, of the catamenia, &c.

EPISCHION, from εϖι and ισχιον, *iſchium*, a name given by the old Greek writers to the pubes.

EPISCOPACY, the quality of epiſcopal government, or that form of church diſcipline, wherein dioceſan biſhops are eſtabliſhed, diſtinct from, and ſuperior to, prieſts or preſbyters. See BISHOP, EPISCOPAL, EPISCOPALIANS, and HIERARCHY.

Epiſcopacy, and preſbytery, have been alternately eſtabliſhed and aboliſhed in Scotland.

EPISCOPACIDE, from εϖισκοϖος, *biſhop*, and *cædo*, *I kill*, the crime of murdering a biſhop by one of his own clergy. By the ancient laws of England, the ſame obedience is due from a clergyman to his biſhop as from a ſervant to his maſter; and therefore the offences of murdering either are made equal, that is, they are both petty treaſon.

EPISCOPAL, ſomething that belongs to a biſhop.

The word is formed of the Greek εϖισκοϖος, *overſeer*, derived from εϖισκοϖεω, *inſpicio*, *I inſpect*, or *overlook*.

Epiſcopal government, is the government of a dioceſe, wherein one ſingle perſon, legally conſecrated, preſides over the clergy of a whole diſtrict, in quality of head, or ſuperintendant thereof; conferring orders, and exerciſing a ſort of juriſdiction.

The preſbyterians reject the epiſcopal eſtabliſhment, and condemn the epiſcopal orders as a human inſtitution, the mere reſult of ſecular policy, or of pride and ambition.

Among the epiſcopal functions, the principal part is that of holding frequent viſitations of the dioceſe.

EPISCOPALES VALVULÆ, called alſo, by ſome, valvulæ mitrales, two valves in the pulmonary vein, which prevent the reflux of the blood to the heart.

EPISCOPALIA, is ſometimes uſed in the ſame ſenſe with pontificalia.

EPISCOPALIA, is alſo uſed to denote ſynodals, or cuſtomary payments, due to the biſhops from the clergy of their dioceſe.

Theſe cuſtomary payments have been otherwiſe called onus epiſcopale; and were remitted, by ſpecial privilege, to free churches and chapels of the king's foundation which were exempt from epiſcopal juriſdiction.

EPISCOPALIANS, or EPISCOPISTS, a name given to thoſe who adhere to the church of England, and particularly to the eccleſiaſtical hierarchy, ſuch as it was in the Romiſh church before the Reformation; who affect the diſcipline of biſhops, prieſts, canons, the office, or liturgy, &c. and retain the greateſt part of the canon law, with the decretals of the popes, more cloſely than the Catholics themſelves of ſeveral countries; though, as to matters of doctrine, or faith, they agree in moſt points with the Calviniſts, or Reformed.

In Scotland, the principal diſſenters are the Epiſcopalians; lay Epiſcopalians enjoy all the ſame civil privileges with thoſe of the eſtabliſhed church. They are under no reſtrictions; tied to no teſts, but are employed in all places of truſt, upon taking the oaths to the government. But the epiſcopal miniſters are liable to ſeveral penal laws; many of them having been nonjurors.

EPISCOPI MULTA. See MULTA.

EPISCOPISSA, a word uſed by writers of the middle ages, to denote a biſhop's wife.

EPISCOPIUS, SIMON, in *Biography*, a Dutch divine of the Arminian perſuaſion, was born at Amſterdam in the year 1583. Having entered on his academical ſtudies in the univerſity of Leyden in 1600, and graduated M. A. in 1606, he purſued his theological ſtudies with great aſſiduity; but on account of the diſputes that ſubſiſted between the Gomariſts and Arminians, he found obſtacles in the way of his admiſſion to the miniſterial office, which the burgomaſters of Amſterdam wiſhed him to aſſume. Diſguſted by this illiberal treatment, he left Leyden in 1609, and removed to the univerſity of Franeker, where he had to contend with ſimilar difficulties, on account of his attachment to the Arminian doctrines. In the year 1710, however, he was admitted to the profeſſion of the miniſtry, and appointed to a church at Bleſwyck, in the neighbourhood of Rotterdam. In the following year he appeared as one of the deputies at the conference held at the Hague, before the ſtates of the province, between ſix anti-remonſtrant and ſix remonſtrant miniſters, where he diſtinguiſhed himſelf by his defence of the opinions of his party. In 1712 he was choſen profeſſor of divinity at Leyden, in the room of Gomarus, who ſurrendered that office. In this ſituation he conducted himſelf with ſingular prudence, as well as ability, ſo that he lived on terms of amity with Polyander, his colleague, who belonged to the party of Gomariſts. The controverſy concerning predeſtination was at this time the occaſion of great animoſity; and Epiſcopius, and his friends, were objects of enmity and perſecution to the deluded populace. Their condition was rendered more perilous by the partiſans of Maurice, prince of Orange, by whom they were calumniated, not only as heretics in their theological ſentiments, but as enemies to the proteſtant religion, and to the United Provinces. At length Maurice and the Gomariſts, of whom he was the head, ſucceeded in obtaining a decree of the States for convening a national ſynod; but the Arminians remonſtrated againſt the meeting of ſuch a ſynod, becauſe they well know that it would be compoſed of their inveterate enemies, who on this occaſion would appear both as their accuſers and their judges. However, it met at Dort in the year 1618, (See *Synod* of DORT,) and the buſineſs of the ſeſſions was conducted as Epiſcopius and his party apprehended. The ruling members were invincible, and required implicit ſubmiſſion to their deciſions. It was in vain that Epiſcopius and his brethren demurred and remonſtrated againſt their proceedings. They were expelled from the ſynod, and their cauſe was tried during their abſence. The reſult was a ſentence, which charged them with peſtilential errors, and with being corrupters of the true religion. This ſentence was followed by their excommunication, a deprivation of their offices, eccleſiaſtical and civil, a prohibition to exerciſe their miniſtry, and beſides fines and impriſonment, baniſhment from the territories of the republic. Accordingly Epiſcopius, as well as ſeveral of his adherents, retired to Antwerp, where he drew up various publications in defence of his oppreſſed party, ſome of which are, "A Confeſſion of Faith," expreſſed for the moſt part in words and phraſes of ſcripture: a treatiſe, entitled "Antidotum adverſus Synodi Dordracenæ Canones," and two letters, addreſſed to Wadingus, a Jeſuit, who wiſhed to ſeduce him into his church, one on the rule of faith, and the other upon the worſhip of images. In 1609, Epiſcopius withdrew into France, and endeavoured to confirm and comfort his brethren, as well as to diffuſe the opinions for which he ſuffered, both by his correſpondence and publications. In 1626, after the death of prince Maurice, and the acceſſion of prince Frederick Henry, he returned to his native country, and enjoyed the benefits of toleration and tranquillity. The place of his ſettlement was Rotterdam, where he exerciſed his miniſtry for about 8 years, and compoſed ſeveral pieces of a theological and controverſial nature, which were publiſhed during his life and after his death. The Arminians, having remained for ſome years unmoleſted, eſtabliſhed a college at Amſterdam, of which Epiſcopius was the firſt theological profeſſor, and this appointment occaſioned his removal to Amſterdam in the year 1634. In the honourable and diligent diſcharge of the duties of this office, he continued till his death, which happened in 1643. Epiſcopius was a man of ſolid and extenſive learning; a cool and accurate judgment, a lively genius, and commanding powers of eloquence. His controverſial pieces, though occaſionally intermixed with unbecoming ardour and bitterneſs, are generally diſtinguiſhed by a ſpirit of candour and moderation. His character was highly exemplary. His ſentiments coincided with thoſe of Arminius, which he reduced into a ſyſtematic form, and recommended by the graces of compoſition. His works, conſiſting of commentaries, theological inſtitutions, controverſial treatiſes, &c. form two volumes in folio; which were edited by Peter Curcellæus, who has prefixed an account of the author. A larger life of him was publiſhed by Philip â Limborch, the ſon of his brother's daughter, written in the Dutch language, of which a Latin verſion appeared at Amſterdam in 1701. 8vo. Bayle. Moſheim. Moreri. Gen. Biog.

EPISCOPUS PUERORUM, *biſhop of the boys*, a ludicrous kind of office, formerly exerciſed in churches, in that called the feaſt of fools, or the feaſt of the kalends. See *Boy* BISHOP.

EPISEMASIA, from εϖισημαινω, *I ſignify*, in *Medicine*, is the very time that a diſeaſe firſt ſeizes a perſon, and is properly called ſignificatio. Blancard.

EPISODE, Εϖεισοδιον, from εϖι, *upon*, and εισοδος, *entry*, is commonly conceived to be a ſeparate incident, ſtory, or action, which an hiſtorian, or poet, inſerts, and connects with his principal action; to furniſh out the work with a greater diverſity of events; though, in ſtrictneſs, all the particular incidents whereof the action or narration is compoſed, are called epiſodes.

EPISODE, in *Dramatic Poetry*, was the ſecond part of the ancient tragedy.

The origin and uſe of epiſodes is deſcribed by M. Hedelin, and F. Boſſu. Tragedy, in its original, being only a hymn ſung in honour of Bacchus, by ſeveral perſons, who made a kind of chorus, or concert of muſic, with dancing, and the like; to diverſify the repreſentation a little, and divert the audience, they determined at length to divide the ſinging of the chorus into ſeveral parts, and to have ſomething rehearſed in the intervals.

At firſt, a ſingle perſon, or actor, was introduced, then two, then more; and what the actors thus rehearſed, or entertained the audience with, being ſomething foreign, or additional to, or beſide, the ſong of the chorus, and no neceſſary part thereof, was called εϖεισοδιον, *epiſode.*

And hence tragedy came to conſiſt of four parts, the prologue, epiſode, exode, and chorus. The prologue was all that preceded the firſt entrance of the chorus, and concluded with the firſt interlude, or choral ode, between the acts. The epiſode, all that was interpoſed between the ſingings of the chorus, and extended in general from the firſt to the laſt of the interludes. The exode, all that was rehearſed after the chorus had done ſinging, or comprehended all that was ſaid after the laſt interlude. And the chorus, was the grex, or company, that ſung the hymn. See each of theſe articles.

And as this recitation of the actors was in ſeveral parts, and inſerted in ſeveral places, it might either be conſidered together as a ſingle epiſode, conſiſting of ſeveral parts; or each part might be called a diſtinct epiſode.

Theſe ſeveral epiſodes in the ſame tragedy might either be taken from ſo many different ſubjects, or from the ſame ſubject divided into a proper number of recitations, or incidents.

To conſider only the firſt occaſion, and inſtitution of theſe foreign or additional pieces, it appears no ways neceſſary, that they ſhould be taken from one and the ſame ſubject; three or four recitations of different actions, no wiſe related, or connected to each other, would eaſe the actors, and amuſe the people, in the intervals of the chorus, as well as if they were all ſo many parts of the ſame action. By degrees, what was at firſt only an addition to the tragedy, became the principal part thereof. Then the ſeveral pieces, or epiſodes, began to be conſidered as one ſingle body which was not to have parts, or members of different nature, and independent of each other.

The beſt poets took the thing in this light, and drew all their epiſodes from the ſame action; which practice was ſo fully eſtabliſhed in Ariſtotle's time, that he lays it down as a rule. Thoſe tragedies wherein this unity and connexion were not obſerved, he called epiſodic pieces. See TRAGEDY.

EPISODE, in *Epic Poetry.* The term epiſode, by being tranſplanted from the ſtage to the epopœia, did not change its nature. All the difference Ariſtotle makes between the tragic and epic epiſodes, is, that the latter are more ample than the former.

Ariſtotle uſes the word in three different ſenſes: the firſt taken from the enumeration already made of the parts of the tragedy, *viz.* prologue, chorus, epiſode, and exode; whence it follows, that in tragedy, every thing is epiſode that is none of the other parts; ſo that as, among us, there are tragedies without either prologue, chorus, or epilogue, the tragic epiſode includes the whole tragedy; conſequently the epic epiſode muſt be the whole poem, in like manner; all there is to retrench from it being the propoſition and invocation, which ſtand in lieu of the prologue. In this ſenſe, the epopœia and tragedy have each only one epiſode; and if the parts or accidents be ill connected together, the poem will be epiſodic and defective.

But farther, as all that was ſung in the tragedy was called the chorus, in the ſingular number, yet this ſingularity did by no means prevent every part or diviſion of the ſame from being called a chorus, without making ſeveral choruſſes; ſo it was with the epiſode; each incident, and part of the fable and action, is not only a part of the epiſode, but it is an epiſode itſelf.

The term epiſode, therefore, in this ſenſe, ſignifies every part of the action expreſſed in the plan, or firſt draught of the fable; as the abſence and wanderings of Ulyſſes, the diſorders in his family, and his preſence, which retrieved and ſet all to rights again.

Ariſtotle furniſhes us with a third kind of epiſode; in ſhewing that what is contained and expreſſed in the firſt plan of the fable is proper, and that all the reſt is epiſode.

By *proper* he means what is abſolutely neceſſary; and by epiſode, what in one ſenſe is neceſſary, and in another not; ſo that the poet is at liberty to uſe, or let it alone.

Thus, Homer, having made the firſt draught of the fable of his Odyſſey, was not at liberty either to make Ulyſſes abſent from his country, or not. His abſence was eſſential; and therefore Ariſtotle ranks it among the things he calls *proper.* But he does not beſtow that appellation on the adventures of Antiphates, Circe, the Sirens, Scylla, Charybdis, &c. The poet was at liberty to have left theſe alone, and to have choſen others in their room; ſo that they are epiſodes diſtinct from the firſt action, to which they are not immediately neceſſary.

The third ſenſe of the word epiſode comes to the ſecond: all the difference between them is, that what we call epiſode in the ſecond ſenſe, is the ground or plan of the epiſode in the third; and that the third adds to the ſecond certain circumſtances which are only probable, and not neceſſary, as the places, princes, and people, among whom Ulyſſes was caſt by Neptune.

It muſt be added, that in an epiſode in the third ſenſe, the incident, or epiſode in the firſt ſenſe, whereon it is grounded, is to be extended and amplified; otherwiſe, an eſſential part of the action and fable does not become an epiſode.

Laſtly, it is in this third ſenſe that we are to underſtand that precept of Ariſtotle, not to make the epiſodes till after the names of the perſons have been choſen. Homer would not have ſpoken of the fleets and ſhips as he has done, if, in lieu of the names of Achilles, Agamemnon, and Iliad, he had choſen thoſe of Adraſtus, Capaneus, and Thebaid.

Upon the whole, the term epiſode, in the epic poem, as uſed by the father of the critics, Ariſtotle, does not ſignify any foreign or accidental adventure; but the whole narration of the poet, or a neceſſary and eſſential part of the action and ſubject, amplified with probable circumſtances.

Thus Ariſtotle enjoins that the epiſode be not added to the action, or fetched from elſewhere; but that it be a part of the action; and never uſes the word *adding*, in ſpeaking of epiſodes, though it occurred ſo naturally to his interpreters, that they have generally uſed it in their tranſlations and comments. He does not ſay, that after laying the plan and chooſing the names, the poet is to add the epiſodes; but uſes the derivative of the word epiſode, επισοδȣν, as if in Engliſh we ſhould ſay epiſodify his action.

From what has been ſaid, we may venture to define epiſodes to be neceſſary parts of the action, extended and filled up with probable circumſtances. Now an epiſode is only a part of an action, and not a whole action; and this part of the action, which is the baſe or ground of the epiſode, muſt not, when epiſodified, retain any thing of the ſimplicity which it had when firſt expreſſed in general, in the plan of the fable.

The ſubject of a poem may be lengthened two ways; either by the poet's making uſe of a great many of his epiſodes; or by his amplifying and giving a greater extent to every one. By this latter method, chiefly, it is, that the epic poets lengthen their poems much beyond the dramatic. It muſt be added, that there are certain parts of an action, which of themſelves do not naturally preſent or afford more than one epiſode; ſuch as the death of Hector, of Turnus, or the like: whereas there are other parts of the fable more copious and fertile, and which oblige the poet to make diverſe epiſodes on each, though laid down in the firſt plan with as much ſimplicity as the reſt: ſuch are the battles of the Trojans and Grecians, the abſence of Ulyſſes; the wanderings of Æneas, &c. For Ulyſſes's abſence ſo many years from his own country, required his preſence elſewhere; and the deſign of the fable was to throw him into ſeveral dangers, and different countries. Now each peril, and each new country, furniſhed an epiſode, which the poet might uſe if he pleaſed.

The reſult of the whole is, that epiſodes are not actions, but parts of actions; that they are not added to the action and matter of the poem, but make the action and matter themſelves; that of courſe they are not to be fetched from elſewhere, but raiſed from the ground or baſis of the action; that they are not united and connected with the action, but with one another; that all the parts of an action are not ſo many epiſodes, but only ſuch as are amplified, and attended with particular circumſtances; and laſtly, that their union with each other is neceſſary in the ground of the epiſode, and probable in the circumſtances.

Epiſodes, ſays Dr. Blair, (Lectures. vol. iii.), as the term is now underſtood, are certain actions, or incidents, introduced into the narration, connected with the principal action, yet not of ſuch importance as to deſtroy, if they had been omitted, the main ſubject of the poem. Of this nature are the interview of Hector with Andromache, in the Iliad; the ſtory of Cacus, and that of Niſus and Euryalus in the Æneid; the Adventures of Tancred with Erminia and Clorinda, in the Jeruſalem; and the proſpect of his deſcendants exhibited to Adam, in the laſt books of Paradiſe Loſt. Such epiſodes as theſe, are not only permitted to the epic poet; but, provided that they be properly executed, are great ornaments to his work. The rules that ſerve to regulate them are ſuch as follow: they muſt be naturally introduced, and have a ſufficient connection with the ſubject of the poem; they muſt ſeem to be inferior parts belonging to it, and not mere appendages annexed to it. In the next place, epiſodes ought to preſent to us objects of a different kind, from thoſe which go before, and thoſe which follow, in the courſe of the poem. For epiſodes are introduced into an epic compoſition, principally for the ſake of variety. Laſtly, as an epiſode is a profeſſed embelliſhment, it ought to be particularly elegant and well-finiſhed; and, accordingly, it is, for the moſt part, in pieces of this kind, that poets put forth their ſtrength. The epiſodes of Taribezus and Ariana, in Glover's Leonidas; and of the death of Hercules, in the Epigoniad, are the two greateſt beauties in theſe poems. With regard to epiſodes in didactic poetry; ſee Didactic *Poetry*.

EPISODIC, in *Poetry*. A fable is ſaid to be epiſodic, when it is ſwelled with unneceſſary incidents; and its epiſodes are not neceſſarily, nor properly, connected with each other.

Ariſtotle lays it down, that thoſe tragedies are moſt defective, whoſe epiſodes have no connection, or dependence on each other, which he calls epiſodic, *q. d.* ſuperabundant in epiſodes; becauſe ſo many little epiſodes can never compoſe one whole one, but neceſſarily remain in a vicious plurality.

If an epiſode be uſed, the names and circumſtances whereof are unneceſſary, and whoſe ground and ſubject make no part of the action, that is, of the matter of the poem, ſuch an epiſode renders the fable epiſodic. This irregularity is diſcovered, when one may take away a whole epiſode, without ſubſtituting any thing in its room; and yet leave no chaſm, or defect, in the poem. The hiſtory of Hypſipule, in Statius's Thebaid, affords an inſtance of theſe faulty epiſodes. If the whole ſtory of that illuſtrious nurſe were retrenched, the ſequel of the principal action would be the better for it. Nor would any body imagine he had forgot any thing, or that there was any member of his action wanting. Boſſu, and Ariſt. Poet. cap. 9.

EPISPASTIC, from ἐπὶ and σπάω, *I draw*, in *Medicine*, a term denoting the quality of thoſe ſubſtances, which, when applied to the ſkin, draw the humours to the part, or excite inflammation and veſication in it. The word, therefore, is nearly ſynonymous with veſicatory, or bliſtering. See Blister.

EPISPHÆRIA, from επι and σφαιρα, *a ſphere*, in *Anatomy*, are windings and turnings in the outer ſubſtance of the brain, that the ſanguiferous veſſels may paſs more ſecurely.

EPISTÆBE, in *Botany*, a name given to the cuſcuta or dodder, found growing on the plant ſtæbe of the ancient Greeks. See Epiphæos.

EPISTAPHYLINUS, in *Anatomy*, a name under which the azygos uvulæ muſcle has been deſcribed. It will be found, in different writers, under the names of ſtaphylinus, columellæ muſculus teres, muſculus uvulæ, or muſcle de la luette. It is deſcribed in the article Deglutition.

EPISTATES, Επιϛατης, derived from επι, *over*, and ιϛημι, *I ſtand*, in *Antiquity*, a perſon who has the command and direction of an affair, or of a people.

The term is of conſiderable uſe, in ſpeaking of the government of Athens, where the epiſtates was the ſenator in command for that day, or whoſe turn it was to preſide that day. The conſtitution was this: the ten tribes of Athens formed by Cliſthenes, elected every year by lot, each of them, fifty ſenators, which made a ſenate of five hundred. Every tribe had the precedence in its turn, and ſurrendered it again ſucceſſively to another. The fifty ſenators in office were called prytanes; the particular place where they aſſembled, prytaneum, and the term, or duration of their office, *viz.* thirty-five days, prytanea. During theſe thirty-five days, ten of the fifty prytanes preſided weekly, under the name of proedri; and of theſe proedri there was one to preſide each day of the week, under the title of epiſtates.

No perſon was allowed to hold his office more than once in his whole life, leſt he ſhould acquire too much the taſte of dominion: the ſenators of all the other tribes ſtill voted, according to the order the lot had given them; but the prytanes laid the buſineſs before them, and the epiſtates took their votes and opinions.

It muſt be added, that of the ten proedri, of each week, there were but ſeven that would preſide each his day in the quality of epiſtates; the ten proedri elected the ſeven prytanes.

EPISTAXIS, from επιϛαζω, *inſtillo*, in *Surgery*, hemorrhage from the noſe.

When bleeding from the noſe takes place in ſuch a degree as to be dangerous, or likely to bring on exceſſive debility, the further effuſion of blood may be ſtopped in the following manner. Roll a conſiderable piece of lint round the end of a probe; wet it completely through with a ſtrong ſolution of the zincum vitriolatum; introduce it into the noſtril, and preſs it as ſtrongly as poſſible againſt the part whence the blood iſſues. As ſoon as the blood ceaſes to flow, we may conclude that the preſſure acts on the bleeding point. This plan generally ſucceeds.

When the blood, however, flows from ſome point which lies very deeply in the noſtril, it might be found impracticable to make preſſure exactly on the bleeding veſſels. At all events, we may then paſs a piece of catgut through the noſtril, and bring it out of the mouth, from the fauces, by means of a pair of common forceps. A tent of lint may next be faſtened to the ligature, and drawn backward through the mouth into the noſe, ſo as completely to ſtop up the poſterior opening of the noſtril. The front aperture may be eaſily filled with a proper doſſil of lint. In this manner, it is clear that no further hemorrhage can happen, as the blood cannot poſſibly find its way outward.

EPISTEMONARCH, derived from επιϛημη, *knowledge*, and αρχη, *command*, a dignitary, in the *Ancient Greek Church*, appointed to watch over the actions of the church, and to inſpect or ſuperintend every thing relating to the faith, in quality of a cenſor. His office anſwered pretty much to that of magiſter ſacri palatii at Rome.

EPISTHOTONOS, from επισθε, *forwards*, and τεινω, *to extend*, in *Surgery*, a ſpecies of tetanus, in which the body is bent forwards. See Tetanus.

EPISTITES, from επιϛημι, *I keep off*, in *Natural Hiſtory*, the name of a ſtone, deſcribed by the writers of the middle ages, as being of a beautiful red, and ſhining very elegantly. It was renowned for its many magical virtues, according to the idle tradition of theſe times; they ſaid it drove away all noxious animals, and kept off ſtorms from the place where any one was who had it about him.

EPISTLE, a letter miſſive.

The word is formed of επιϛελλω, *I ſend*.

The term epiſtle is now ſcarcely uſed, but for letters wrote in verſe, and letters dedicatory.

In ſpeaking of letters written by moderns, or rather in the modern languages, we never uſe the word epiſtle. Thus, we ſay, the letters, not epiſtles of the cardinal D'Oſſat, of Voiture, of Balzac, of Howel, of Pope, &c.: but thoſe wrote by the ancients, or rather in the ancient language, we call epiſtles; as the epiſtles, not letters in Cicero, Pliny, Seneca. The epiſtles of St. Paul, St. Peter, St. John, &c. to the Romans, Corinthians, &c.

A Table of St. Paul's Epiſtles, in the order of time, with the places where, and the times when they were written.

Epiſtles.	Places.		A.D.
1 Theſſalonians 2 Theſſalonians	Corinth		52
Galatians	Corinth, or Epheſus	Near the end of or the beginning of	52 53
1 Corinthians	Epheſus	The beginning of	56
1 Timothy	Macedonia		56
Titus	Macedonia, or near it	Before the end of	56
2 Corinthians	Macedonia	About October	57
Romans	Corinth	About February	58
Epheſians	Rome	About April	61
2 Timothy	Rome	About May	61
Philippians	Rome	Before the end of	62
Coloſſians	Rome	Before the end of	62
Philemon	Rome	Before the end of	62
Hebrews	Rome, or Italy	In the ſpring of	63

A Table of the Seven Catholic Epiſtles, ſo called becauſe they were written to Chriſtians in general, and the Revelation, with the places where, and the times when they were written.

Epiſtles.	Places.		A.D.
The Epiſtle of St. James	Judea	61 or beginning of	62
The 2 Epiſtles of St. Peter	Rome		64
St. John's 1ſt Epiſtle	Epheſus	About	80
His 2d and 3d Epiſtles	Epheſus	Between	80 and 90
The Epiſtle of St. Jude	Unknown		60 or 65
The Revelation of St. John	Patmos, or Epheſus		95 or 96

See Lardner's Credibility of the Goſpel Hiſtory, vol. xvi. and vol. xvii.

Learned writers are not abſolutely agreed as to the dates of theſe ſeveral epiſtles, nor the places whence they were written. It would lead us too far to examine and produce the various authorities and arguments that have been uſed for ſettling theſe particulars: we ſhall only mention that Dr. Doddridge dates the 1ſt Epiſtle to the Corinthians about the year 57; and the 2d Epiſtle in 58; thoſe to the Epheſians, Philippians, Coloſſians, and Philemon, in 63; the 1ſt to Timothy, in 58 or 65; the 2d to Timothy, in 66 or 67; the Epiſtle to Titus, between St. Paul's firſt and ſecond impriſonment at Rome; the Epiſtle of St. James, in 60 or 61; the 1ſt of Peter in 61; the 2d, in 67; that of St. Jude, ſome time after the 2d of Peter, according to Dr. Mills, in the year 90. As to the general deſign of theſe ſeveral epiſtles, it is obſerved by Dr. Doddridge, who is deſervedly eſteemed an excellent and uſeful expoſitor, that the Epiſtle to the Romans is intended to fix in the minds of the Chriſtians, to whom it is addreſſed, a juſt ſenſe of the excellency of the goſpel, and to engage them to act in a manner agreeable to their profeſſion of it: the Epiſtles to the Corinthians are deſigned to reſolve ſome important queries propoſed by them, and to correct the various criminal irregularities and diſorders, of which they were guilty: the principal deſign of the Epiſtle to the Galatians was to aſſert and vindicate the apoſtle's authority and doctrine, and to confirm the churches of Galatia in the faith of Chriſt, eſpecially wih reſpect to the important point of juſtification; to expoſe the errors that were introduced among them, and to revive thoſe principles of Chriſtianity which he had already taught them. In the Epiſtle to the Epheſians, that apoſtle endeavours to eſtabliſh them in the faith; and to this end to give them more exalted views of the divine love and the excellence of Chriſt; to ſhew them that they were now, though Gentiles, made partakers of equal privileges with the Jews; to encourage them, by his own example and concern for their welfare; and to engage them to the practice of duties becoming their Chriſtian character. The Epiſtle to the Philippians is deſigned to comfort them under the concern they felt on his account; to check a party-ſpirit that had broke out among them, and to promote union and affection; to guard them againſt the ſeduction of judaizing teachers; to ſupport them under their trials, and to inſpire them with an ambition of excelling in ornamental and diſtinguiſhed attainments. The Epiſtle to the Coloſſians is deſigned to excite them to a temper and conduct worthy of their ſacred character, and to ſecure them from the influence of thoſe Pagan ſophiſts or Jewiſh bigots, who endeavoured to ſeduce them from the purity of the Chriſtian faith. The two Epiſtles to the Theſſalonians are intended to confirm them in their adherence to the Chriſtian faith, and to engage them, from the ſufferings they had already endured, and the extraordinary character they had hitherto maintained, to make great advances, and to excel ſtill more in religion and virtue; and alſo to rectify ſome erroneous apprehenſions they entertained about the coming of Chriſt, and to direct them in the proper exerciſe of Chriſtian diſcipline The firſt Epiſtle of Timothy was partly intended to direct him in managing the affairs of the church, and chooſing proper perſons for the various offices it required; and partly to caution him againſt the influence of judaizing teachers, to urge him to pay a conſtant regard to the intereſts of practical religion, and to animate him to diligence, fidelity, and zeal. The ſecond epiſtle prepares Timothy for the ſufferings that awaited him, forewarns him of the apoſtacy that was beginning to appear in the church, and animates him to the perſevering diſcharge of every part of the miniſterial office. The Epiſtle to Titus contains a variety of prudent inſtructions and cautions. The deſign of the Epiſtle to the Hebrews was to confirm the Jewiſh Chriſtians in the faith and practice of the goſpel, which they might be in danger of deſerting through the inſinuation or ill-treatment of their perſecutors. St. James, in his epiſtle, aims to correct theſe errors both in doctrine and practice into which the Jewiſh Chriſtians had fallen, which might otherwiſe have produced fatal conſequences; and then to eſtabliſh the faith, and animate the hope of ſincere believers under their preſent and approaching ſufferings. The Epiſtles of St. Peter are deſigned to induce the Chriſtian converts in various parts of the world to maintain a conduct inoffenſive and amiable; to ſupport them under their trials, and to encourage their conſtancy, notwithſtanding the artifices of falſe teachers, and the perſecution of their moſt inveterate enemies. The leading deſign of St. John in his firſt epiſtle, is to evince the vanity of faith ſeparate from morality; to inſpire the minds of Chriſtians with mutual charity, and to guard them againſt the ſnares and efforts of Antichriſt, and of all who were endued with his ſpirit. The Epiſtle of Jude deſcribes the characters of the falſe teachers, repreſents the divine judgments which ſuch perſons had reaſon to expect, and thus cautions Chriſtians againſt being perverted by them. See Doddridge's Fam. Expoſitor, vol. iv. v. and vi. in the general introduction prefixed to each epiſtle. See alſo an account of the writers of theſe epiſtles, and of the churches to which they were addreſſed.

Epistle, *Poetical*, a ſpecies of didactic poetry, the ſubjects of which are the manners and characters that occur in ordinary life, and that require to be treated with ſomewhat of the eaſe and freedom of converſation. When theſe epiſtles are employed on moral and critical ſubjects, they ſeldom riſe into a higher ſtrain of poetry than *ſatires*, which ſee. Many other ſubjects may be diſcuſſed in the form of an epiſtle; ſuch as love poetry, or elegiac; ſpecimens of which occur in Ovid's "Epiſtolæ Heroidum," and his "Epiſtolæ de Ponto." As theſe works are deſigned to be merely ſentimental, and their merit conſiſts in being proper expreſſions of the paſſion or ſentiment which forms the ſubject, they may aſſume any tone of poetry that is ſuited to it. But didactic epiſtles ſeldom admit of much elevation. The poet, commonly reſtricting himſelf to obſervations on authors, or on life and characters, and not intending to compoſe a formal treatiſe, or to confine himſelf ſtrictly to regular method, gives ſcope to his genius on ſome particular theme, which, at the time, has prompted him to write. Much of the grace of this kind of writing conſiſts in a ſpirited conciſeneſs, which gives to ſuch compoſition an edge and livelineſs, that ſtrike the fancy and keep attention awake. Much of their merit depends alſo on juſt and happy repreſentations of characters. Unſupported by thoſe high beauties of deſcriptive and poetical language, which adorn other compoſitions, the reader expects them to entertain him with lively paintings of men and manners; and therefore in theſe a certain ſprightlineſs and turn of wit find their proper place, and contribute to the beauty and effect. Of this kind of poetry Mr. Pope's ethical epiſtles furniſh an almoſt perfect model. In theſe his wit diſcovers itſelf to ſuch a degree as to give a proper ſeaſoning to grave reflections. His paintings of characters are natural and lively; and, never was any writer ſo happy in that conciſe ſpirited ſtyle, which gives animation to ſatires and epiſtles. His rhyme likewiſe adds to the ſtyle an elevation which otherwiſe it could not have poſſeſſed, while at the ſame time he manages it ſo artfully, that it never appears in the leaſt to incumber him, but, on the contrary, ſerves to increaſe the livelineſs of his manner. In this ſpecies of writing, eaſe and elegance are the diſtinguiſhing characters; nothing, therefore, ſhould be forced or unnatural, laboured or affected, but every part of the compoſition ſhould manifeſt an eaſy, polite, and unconſtrained freedom.

EPISTOLARES, among the Romans, under-ſecretaries to the "magiſter ſcrinii epiſtolarum," or ſecretary who wrote the emperor's leters. They were thirty-four in number. See MAGISTER.

EPISTOLARY, a term uſed in the phraſe epiſtolary ſtyle. As the matter of an epiſtle is the ſame with that of converſation, it ſhould not differ in the manner of expreſſion; and, therefore, all pomp and ſtudy of language are not only needleſs but very improper: the moſt plain and eaſy way of conveying our thoughts muſt certainly be beſt, as being moſt natural. Purity in the choice of words, and juſtneſs of conſtruction, joined with perſpicuity, are the chief properties of this ſtyle: to which purpoſe Cicero obſerves, "that in writing letters we make uſe of common words and expreſſions." (Ad Fam. lib. ix. cap. 21.) And Seneca ſays, "I would have my letters be like my diſcourſes, when we either ſit or walk together, unſtudied and eaſy." (Ep. 75. ad Lucill.)

The firſt and fundamental requiſite in epiſtolary writing is to be natural and ſimple, for a ſtiff and laboured manner is as bad in a letter as in converſation. This does not baniſh ſprightlineſs and wit. Theſe are graceful in letters as well as in converſation; when they flow eaſily, and without being ſtudied; when employed ſo as to ſeaſon, and not to clog. A perſon, who either in converſation or in letters affects to ſhine and ſparkle always, will not pleaſe long. The ſtyle of letters ſhould be neat and correct, but not too highly poliſhed. Nicety about words betrays ſtudy; and on this account muſical periods, and appearances of number and harmony in arrangement, ſhould be carefully avoided in letters. Thoſe that are written with the greateſt facility are commonly the beſt. Nevertheleſs, it ſhould be remembered, that the eaſe and ſimplicity of epiſtolary writing are not to be underſtood as importing entire careleſsneſs. In writing to the moſt intimate friend, a certain degree of attention, both to the ſubject and the ſtyle, is requiſite and becoming. The firſt requiſite both in converſation and correſpondence, is to regard all the proper decorums, which our own character, and that of others demand. An imprudent expreſſion in converſation may be forgotten and paſs away; but with the pen in hand, we ſhould remember the well-known adage, "Litera ſcripta manet."

As the ſubjects of epiſtles are various, they will neceſſarily acquire ſome variety in the manner of expreſſion. If the ſubject be weighty and momentous, the language ſhould be ſtrong and ſolemn; in things of a lower nature, more free and eaſy; and upon lighter matters, jocoſe and pleaſant. In exhortations, it ought to be lively and vigorous; in conſolations, kind and compaſſionate; and in adviſing, grave and ſerious. In narratives, it ſhould be clear and diſtinct; in requeſts, modeſt; in commendations, friendly, without adulation; in proſperity, chearful; and mournful, in adverſity. In a word, the ſtyle ought to be accommodated to the particular nature of the ſubject about which it is converſant. Although there ſhould be nothing very conſiderable in the ſubject; yet if the ſpirit and turn of the correſpondence be agreeable, if the letters be written in a ſprightly manner, and with native grace and eaſe, they may ſtill be entertaining, more eſpecially if there be any thing to intereſt us in the characters of thoſe who write them. As letters from one friend to another make the neareſt approach to converſation, we may expect to ſee more of character diſplayed in theſe than in other productions, which are ſtudied for public view. We are pleaſed with beholding a writer ſo ſituated as to allow him to be at his eaſe, and to give occaſional vent to the overflowings of his heart. Beſides, the different character of the perſon, to whom the letter is written, requires a like difference in the modes of expreſſion. Superiors ſhould be addreſſed with reſpect; inferiors, with courteſy; and equals, with civility. Old men and young, the grave and facetious, courtiers and philoſophers, friends and ſtrangers, require ſome variety in the mode of addreſs. The epiſtles of Cicero, the ſtyle of which is plain and ſimple, and yet pleaſant and engaging, furniſh a proper model in this reſpect. They are the moſt valuable collection of letters in any language, as they are letters of real buſineſs, written to the greateſt men of the age, compoſed with purity and elegance, but without the leaſt affectation; and, what adds greatly to their merit, written without any intention of being publiſhed to the world. Pliny's letters are elegant and polite; and exhibit a very pleaſing and amiable view of the author; but, according to the vulgar phraſe, they ſmell too much of the lamp. They are too elegant and fine: and the author ſeems to be caſting an eye towards the public, when he is appearing to write only to his friends. His ſtyle abounds ſo much with turns and quibbles upon the ſound of words, as to render it more ſtiff and affected than agrees with converſation, or than a man of ſenſe would chooſe to uſe in diſcourſe, if it were in his power. This, indeed, was owing to the age in which he lived, at which time the Roman eloquence was ſunk into puns, and an affectation of wit; for Pliny was otherwiſe a man of fine ſenſe and great learning. We need not here recommend Melmoth's tranſlation of the letters of Cicero and Pliny. The moſt diſtinguiſhed collection of letters in the Engliſh language is that of Mr. Pope, Dean Swift, and their friends; publiſhed partly in Mr. Pope's works, and partly in thoſe of Dean Swift. Many letters in this collection are written with eaſe and a beautiful ſimplicity. Thoſe of Dr. Arbuthnot deſerve this commendation. Dean Swift's are unaffected. Several of lord Bolingbroke's and of biſhop Atterbury's letters are maſterly. Mr. Pope's are too artificial. Among the French in the laſt age, Balzac and Voiture were the two moſt celebrated epiſtolary writers. Balzac's periods are ſwelling, and his ſtyle pompous; ſo that his reputation ſoon declined. Voiture continued for a long time a favourite author. His compoſition is extremely ſparkling; he manifeſts much wit, and trifles agreeably. His only fault is, that he is too open and profeſſed a wit, to be thoroughly agreeable as a letter-writer. The letters of Madam de Sevigné are now eſteemed the moſt accompliſhed model of a familiar correſpondence. Trifling as are their ſubjects, and overloaded as they are with compliments, they ſhew ſuch perpetual ſprightlineſs, they contain ſuch eaſy and varied narration, and ſo many ſtrokes of the moſt lively and beautiful painting, perfectly free from any affectation, that they are juſtly entitled to high praiſe. The letters of lady Mary Wortley Montague poſſeſs much of the French eaſe and vivacity, and retain more the character of agreeable epiſtolary ſtyle, than perhaps any letters which have appeared in the Engliſh language. Ward's Orat. vol. ii. p. 213, &c. Blair's Lect. vol. iii. Lect. 37. See STYLE.

EPISTOLARY is ſometimes alſo applied to authors who have wrote epiſtles or letters. The principal epiſtolary authors are Sidonius Apollinaris, Tully, the younger Pliny, Seneca the philoſopher, Petrarch, Politian, Buſbequius, Eraſmus, Lipſius, Muretus, Aſcham, Milton, Petau, Launci, Sarau, Balzac, Voiture, ſir W. Temple, Lyttelton, &c. &c. See the preceding Article.

EPISTOMIA, in *Anatomy*, are the utmoſt gapings and meetings of veſſels.

EPISTOMIUM, Επιςομιον, from επι, *upon*, and ςομα, *mouth*, in *Hydraulics*, a plug or inſtrument, by the application whereof the orifice of a veſſel may be opened and ſhut again at pleaſure.

EPISTROPHE, Επιϛροφη, in *Rhetoric*, a figure wherein that which is ſuppoſed of one thing is ſtrongly affirmed of another, and the repetition of the ſame word occurs at the end of each member or ſentence:

"Since concord was loſt, friendſhip was loſt, fidelity was loſt, liberty was loſt, all was loſt." Auct. ad Herenn. lib. iv. cap. 13. See alſo 2 Cor. xi. 22.

EPISTROPHEUS, in *Anatomy*, from επι, *upon*, and ϛρεφω, *I turn*, a name given to the ſecond vertebra of the neck, round a particular proceſs of which the firſt vertebra turns. See SPINE.

EPISTYLE, Επιϛυλιον, from επι, *upon*, and ϛυλος, *column*, in the *Ancient Architecture*, a term uſed by the Greeks for what we call architrave, *viz.* a maſſive ſtone, or a piece of wood, laid immediately over the capital of a column.

The epiſtyle is the firſt or loweſt member of the entablature.

EPITAPH, Επιταφιον, from επι, *upon*, and ταφος, *ſepulchre*; a monumental inſcription, in honour or memory of a perſon defunct; or an inſcription engraven or cut on a tomb, to mark the time of a perſon's deceaſe, his name, family, and uſually ſome eloge of his virtues or good qualities.

At Sparta, epitaphs were only allowed to people who died in battle. Boxhornius has made a collection of epitaphs, not very ample, but exceedingly well choſen. F. Labbe has likewiſe given a collection of the like kind in French, intitled, "Treſor des Epitaphes." Camden, Weaver, and Toldervy, have done ſomething in the ſame way with our Engliſh epitaphs.

In epitaphs, the dead perſon is ſometimes introduced by way of proſopopœia, ſpeaking to the living; of which we have a fine inſtance, worthy the Auguſtan age, wherein the dead wife thus beſpeaks her ſurviving huſband.

"Immatura peri: ſed tu, felicior, annos
Vive tuos, conjux optime, vive meos."

The French have a proverb, "Menteur comme une epitaphe: He lies like an epitaph;" an alluſion to the eloges ordinarily contained therein, which are not always over-juſt.

EPITAPH, is alſo applied to certain eloges, either in proſe or in verſe, compoſed without any intent to be engraven on tombs.

The elegance of an epitaph conſiſts in a nervous and expreſſive brevity, and it is ſometimes cloſed with an epigrammatic point. It is obſerved by Dr. Johnſon, in his life of Pope, that the difficulty of writing an epitaph conſiſts, in giving a particular and appropriate praiſe. This, he ſays, is not always to be performed, whatever be the diligence or ability of the writer; for the greater part of mankind have no character at all, or little that diſtinguiſhes them from others equally good or bad; and, therefore, nothing can be ſaid of them, which may not with equal propriety be applied to a thouſand more.

In the Anthologies, or collections of epigrams, we have abundance of epitaphs, ſome of them ludicrous and ſatirical, others grave. For a ſpecimen, we ſhall here add a very beautiful one, compoſed by Mr. Cowley, on himſelf, to be put in a little country-houſe, whither he retreated from the court and town to ſpend his laſt days.

"Hic, O viator, ſub lare parvulo,
Couleius hic eſt conditus, hic jacet
Defunctus humani laboris
Sorte, ſupervacuaque vita;
Non indecora pauperie nitens,
Et non inerti nobilis otio,
Vanoque dilectis popello,
Divitiis, animoſus hoſtis.
Poſſis ut illum dicere mortuum,
En terra jam nunc quantula ſufficit
Exempta ſit curis, viator,
Terra ſit illa levis, precare.
Hinc ſparge flores, ſparge breves roſas;
Nam vita gaudet mortua floribus;
Herbiſque odoratis corona
Vatis adhuc cinerem calentem."

The following epitaphs, beſides many others, are worth recording. That of Alexander:

"Sufficit huic tumulus, cui non ſufficeret orbis."

That of Newton:

"Iſaacum Newton
Quem immortalem
Teſtantur Tempus, Natura, Cœlum,
Mortalem hoc marmor
Fatetur."

That of Dryden:

"Dryden."

Similar to which is that which the Italians have annexed to the tomb of Taſſo:

"Les os du Taſſe."

The following epitaph on the ſiſter of ſir Philip Sidney, the counteſs of Pembroke, and ſaid to be written by the famous Ben Jonſon, is diſtinguiſhed by its admirable concluſion:

"Underneath this noble marble hearſe
Lies the ſubject of all verſe,
Sidney's ſiſter, Pembroke's mother:
Death, ere thou haſt kill'd another
Fair, and learn'd, and good as ſhe,
Time ſhall throw a dart at thee."

The following alſo by the ſame author is well known, and has been much admired:

"Underneath this ſtone doth lie
As much virtue as could die;
Which, when alive, did vigour give
To as much beauty as could live."

Another epitaph, by Dr. Samuel Johnſon, on a celebrated muſician, deſerves to be recorded, as it is equalled by few, and ſurpaſſed by none.

"Philips! whoſe touch harmonious could remove
The pangs of guilty pow'r and hapleſs love,
Reſt here, diſtreſt by poverty no more;
Find here that calm thou gav'ſt ſo oft before;
Sleep undiſturb'd within this peaceful ſhrine,
Till angels wake thee with a note like thine."

The following epitaphs are ſpecimens of the ſatirical or ludicrous kind:

Prior on himſelf, ridiculing the folly of thoſe who value themſelves on their pedigree.

"Nobles and heralds, by your leave,
Here lie the bones of Matthew Prior,
The ſon of Adam and of Eve;
Let Bourbon or Naſſau go higher."

On a Miſer.

" Reader, beware of immod'rate love of pelf;
Here lies the worſt of thieves, who robb'd himſelf."

A ſimilar epitaph by Dr. Swift.

" Beneath this verdant hillock lies
Damer, the wealthy and the wiſe.
His heirs, that he might ſafely reſt,
Have put his carcaſe in a cheſt;
The very cheſt, in which, they ſay,
His other ſelf, his money, lay.
And if his heirs continue kind
To that dear ſelf he left behind,
I dare believe that four in five
Will think his better half alive."

We ſhall here ſubjoin the epitaph of the ingenious and laborious author of the Cyclopædia, from his tomb in the cloiſters of Weſtminſter Abbey, on the north ſide, written by himſelf:

" Multis pervulgatus,
Paucis notus;
Qui vitam inter lucem et umbram,
Nec eruditus, nec idiota,
Literis deditus tranſegit; ſed ut homo
Qui humana nihil a ſe alienum putat,
Vita ſimul et laboribus functus,
Hic requieſcere voluit
Ephraim Chambers,
R. S. S.
Obiit 15 Maij, 1740."

In Engliſh thus:

" Heard of by many,
Known to few;
Who led a life between fame and obſcurity;
Neither abounding nor deficient in learning;
Devoted to ſtudy; but as a man
Who thinks himſelf bound to all offices of humanity;
Having finiſhed his life and labour together,
Here deſires to reſt.
Ephraim Chambers."

We ſhall cloſe this article with ſome pertinent remarks on epitaphs, by an anonymous writer in the " Olla Podrida." The peruſal of epitaphs is not to be conſidered as a light and frivolous amuſement. If ſuch only be the object of attention, as have been noticed with our applauſe, it is unqueſtionably an introduction to pleaſing knowledge, and an incentive to moral improvement. What biography is to hiſtory, an epitaph is to biography. It is a ſketch which marks the great outlines of character, and excites curioſity to view the portraits as painted in the pages of hiſtory. It is likewiſe an epitome of a ſermon, which teaches the moſt uſeful truths in the moſt comprehenſive form. Monumental inſcriptions remind us, that time is on the wing, that every rank and age muſt fall a prey to his depredations; that the moments of life are too precious to be ſquandered away on trifles; that religion is the only ſupport againſt the horrors of death, and the only guide to the joys of eternity.

EPITASIS, formed of επιτεινω, *intendo*, *I heighten*, in the *Ancient Poetry*, denoted the ſecond part or diviſion of a dramatic poem, wherein the plot or action propoſed and entered upon in the firſt part or protaſis was carried on, heightened, warmed, and worked up, till it arrives at its ſtate or height called the cataſtaſis.

This diviſion is laid aſide in the modern drama; in lieu whereof our plays are divided into acts. See Act.

The epitaſis might ordinarily take up about our ſecond or third act.

Epitasis, in *Medicine*, denotes the increaſe or growth and heightening of a diſeaſe; or the beginning of a paroxyſm, particularly in a fever.

EPITHALAMIUM, Επιθαλαμιον, formed of επι, and θαλαμος, *bride-chamber*, in *Poetry*, a nuptial-ſong, or a compoſition, uſually in verſe, on occaſion of a marriage between two perſons of eminence.

The topics it chiefly inſiſts on are the praiſes of matrimony, and of the married couple, with the pomp and order of the marriage ſolemnity: it concludes with prayers to the gods for their proſperity, their happy offſpring, &c. This kind of poetry is very ancient: the 44th Pſalm, and the book of Canticles have been conſidered as ſpecimens of the epithalamium. Steſichorus, who flouriſhed in the forty-ſecond Olympiad, has been uſually eſteemed the inventor of the epithalamium among the Greeks, though it is known that Heſiod compoſed the epithalamium of Thetis and Peleus, a work now loſt; but a fragment of which is preſerved by an ancient ſcholiaſt. Catullus exceeded all antiquity in his epithalamiums, and the cavalier Marino all the moderns.

Among the Greeks, the epithalamium was ſung by young men and maids at the door of the bed-chamber of the married pair in the evening and morning. The former ſort were called επιθαλαμια κοιμητικα, and the latter εγερτικα.

EPITHEM, Epithema, from επι, *upon*, and τιθημι, *pono*, *I put*, in *Pharmacy*, a kind of fomentation or remedy, of a ſpirituous or aromatic kind, applied externally to the regions of the heart, liver, &c. to ſtrengthen and comfort the ſame, or to correct ſome intemperature thereof.

There are principally three kinds of theſe external applications, the liquid, the ſolid, and the ſoft or poultice kind. See Cataplasm and Fomentation.

Epithem, *Volatile*, *epithema volatile*, a form of medicine preſcribed in the late London Pharmacopœia, and ordered to be made of equal weights of common turpentine and ſpirit of ſal armoniac. The turpentine is to be kept continually ſtirring in a mortar, and the ſpirit gradually dropt in till the whole is reduced to a white maſs.

The ſpirit of ſal armoniac uſed in this mixture muſt not be that made in the common way, with the addition of quick-lime, but with the alkali ſalt. Pemberton's Lond. Diſp. p. 377.

EPITHE'SIS, from επι and τιθημι, *to lay upon*, an old term in *Surgery*, the meaning of which was the ſtraightening of deformed limbs by mechanical contrivances.

EPITHET, Επιθετον, a noun adjective, expreſſing ſome quality of a ſubſtantive to which it is joined.

The word is formed of επι, *upon*, and θεσις, *poſitio*, *putting*. As a fruitful vine, a ſtately pile, an echoing vault, &c.

Epithets are of great uſe and conveniency among poets and orators, who ſupply in epithets what they want in other requiſites. Card. Perron even blames Homer on the head of epithets, obſerving, that he frequently hooks in epithets without any ſenſe or ſignificancy at all, to help out his meaſures; and that he equips every hero with an epithet, not according to the exigence of the caſe, but the meaſure of the verſe.

Epithet, is alſo uſed for a ſurname, or a perſon's ſecond appellation.

Epithets were anciently beſtowed very frankly, either on account of excellencies or defects of the body or mind; kings themſelves were not exempted from them. Hence theſe thoſe epithets ſo frequent in hiſtory, as Edward Longſhanks, Richard Cœur de Leon, Edmund Iron-ſide, Richard Crook-back, John Lack-land, &c.

Nor have the French uſed their kings any better; witneſs their Charles the Simple, Louis the Lazy, faineant (Ludovicus nihil faciens) Pepin the Short, Louis the Stammerer, le begue.

EPITHRICADIA, in *Antiquity*, a feſtival in honour of Apollo.

EPITHYME. See Dodder, and Epitheos.

EPITOME, an abridgment, or a reduction of the principal matters of a larger book into a little compaſs. See Abridgment.

The word is Greek, επιτομη, formed of επιτεμνειν, *reſecare, to retrench, abridge,* or *cut off.*

The epitome of Baronius's Annals is done by De Sponde (Spondanus). Bernier has given an epitome of the philoſophy of Gaſſendus.

It is a popular objection againſt the epitomizing of authors, that it frequently occaſions the loſs of the originals. Thus the loſs of the hiſtorian Trogus Pompeius is attributed to his epitomizer Juſtin, and the loſs of a great part of Livy to Luc. Florus. See Livy.

"Epitomes," ſays the learned Bacon, "are the moths and corruptions of hiſtory, that have fretted and corroded the ſound bodies of many excellent hiſtories, and wrought them into baſe and unprofitable dregs."

EPITRITES, from επι, and τριτος, *third,* in *Proſody,* a foot conſiſting of four ſyllables, three long, and one ſhort.

Grammarians reckon four ſpecies of epitrites; the firſt, conſiſting of an iambus and ſpondee, as ſălūtāntēs; the ſecond, of a trochee and ſpondee, as cōncĭtātī; the third, of a ſpondee and an iambus, as cōmmūnĭcāns; and the fourth, of a ſpondee and trochee, as īncāntārĕ.

Epitrites, among the *Greek Muſicians,* denoted a ratio, called alſo the ſeſquitertial ratio, the ſame with that of three to four. See Fourth.

EPITROCHASMUS, in *Rhetoric,* a figure wherein we ſlightly paſs over ſeveral things of great moment, by only mentioning them in general. Such is the ſaying of Cæſar, *Veni, vidi, vici.*

EPITROPE. See Concession. This is one of the figures of ſentences, which grants one thing to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or only a part is granted. Nothing more confounds an adverſary, than to grant him his whole argument, and at the ſame time either to ſhew that it is nothing to the purpoſe, or to offer ſomething elſe, which may invalidate it. Of the uſe of this figure we have examples in Cicero's defence of Ligarius, who was accuſed by Tubero for having joined with Pompey in the civil war between him and Cæſar, (cap. 1.); and in the affair of Roſcius, where the proof depended upon circumſtances; and when Cicero, who defended him, inquires what reaſon could be alledged for his committing ſo black a crime, as to kill his father, (cap. 27.) Cicero has alſo given us an example of a feigned or ironical conceſſion in his defence of Flaccus (cap. 38.); when interceding for him on account of his former good ſervices, in the time of Catiline's conſpiracy, he ſays in the way of irony, if ſuch things are to be overlooked, "let us appeaſe the ghoſts of Lentulus and Cethegus; let us recall thoſe who are in exile, and let us be puniſhed for our too great affection and love for our country." To theſe feigned conceſſions we may refer ſuch modes of reaſoning, by which the orator both juſtifies a charge brought againſt him, upon the ſuppoſition of its being true; and alſo proves that the charge itſelf is falſe. Thus Cicero, in his defence of Milo, repreſents the taking off of Clodius, with which Milo was accuſed, as a glorious action; after he has ſhewn that Milo's ſervants did it without the knowledge of their maſter. (Cap. 10. and 27.)

EPITROPUS, a kind of judge, or rather an arbitrator, which the Greek Chriſtians under the dominion of the Turks elect in the ſeveral cities, to terminate the differences that ariſe among them, and avoid carrying them before the Turkiſh magiſtrates. See Arbitrator.

There are ſeveral epitropi in each city. M. Spon, in his Travels, obſerves, that at Athens there are eight taken out of the ſeveral pariſhes, and called vecchiardi, *i. e.* old men. But Athens is not the only place where there are epitropi; they are in all the iſlands of the Archipelago.

Some Latin authors of the ſixth century call epitropi thoſe who more anciently were called villici, and ſince vidames.

In times ſtill earlier, the Greeks uſed the term επιτροπος, in the ſame ſenſe as the Latins did *procurator, viz.* for a commiſſioner or intendant.

Thus the commiſſioners of proviſions in the Perſian army are called by Herodotus and Xenophon epitropi. In the New Teſtament, επιτροπος denotes the ſteward of a houſehold, rendered in the vulgate procurator.

EPIZEUXIS, in *Rhetoric,* a figure where the ſame word is repeated with vehemence in the ſame ſenſe, without any others intervening, and ſuited to expreſs anger, ſurpriſe, ſorrow, and ſeveral other paſſions: thus *age, age; adeſte, adeſte;* and that of Virgil, *nunc, nunc inſurgite remis,* are inſtances of it. Thus alſo, when Cicero would expreſs his indignation againſt Antony for having been the chief inſtrument in bringing on the civil war, he ſays to him: "You, you, Antony, puſhed Cæſar upon the civil war." (Philip. ii. c. 22.) Thus he tells Catiline in his firſt invective againſt him; "You live, and live, not to lay aſide, but to purſue your wicked deſign." (Ibid. cap. 2.) See Matthew xxiii. 37. The uſe of this figure ſhews the earneſtneſs of the ſpeaker and the great concern of his mind about what he ſays, and has a natural tendency to excite the attention of the audience.

EPIZOOTIC Strata, or *Mountains,* in *Geology,* are ſuch as contain remains of animals, which a very large portion of all thoſe upon the ſurface of the earth ſeem to do, although their reliquiæ are by no means equally numerous in all ſtrata, probably owing to their not being preſerved in every inſtance, ſo that their remains or impreſſions can be now traced.

EPIZOOTY, a denomination given to an epidemical or contagious diſtemper among horned cattle. M. de Saive, apothecary to the prince biſhop of Liege, has given the following inſtructions for the prevention and cure of this diſorder. As ſoon as any ſymptoms of the diſtemper are perceived, about $1\frac{1}{2}$ pint of blood ſhould be taken from the beaſt, unleſs he has been ill a day or two, in which caſe he ſhould not be blooded; but in both caſes the following draught ſhould be given, *viz.* N° 1. an ounce of the beſt Venice treacle diſſolved in a pint of vinegar, after which the back-bone and the whole hide muſt be well rubbed with a dry hair cloth, to heat the hide and promote perſpiration. No drink ſhould be given him but a white drink compoſed of (N°. 2.) a handful or two of rye-meal in a pailful of clean water; and if the beaſt ſhould want food, mix up ſome crumbs of rye bread with ſome of this white drink, and give it him. The animal's mouth muſt be waſhed twice a day with a cloth dipped in a mixture of (N°. 3.) equal quantity of vinegar and water, with a ſpoonful of honey to a pint of it. If on the ſecond day the beaſt has not dunged, a clyſter compoſed of (N°. 4.) a pint of water in which bran has been boiled, two ſpoonfuls of ſalt, and a ſmall glaſs of vinegar muſt be given and repeated every day till the evacuations are natural and regular. Beſides the above remedies, the following cordial mixture (N°. 5.) *viz.* a pint of clear water, the ſame quantity of vinegar, four ſpoonfuls of honey or ſyrup, and two glaſſes of brandy, muſt be given four times a day to facilitate and keep up perſpiration; taking particular care to repeat the friction as above directed. If the beaſt ſhould ſtill continue low and heavy, the draught (N°. 1.) muſt be repeated, unleſs he ſhould be found to be hot and thirſty, in which caſe only the drink (N°. 2.) ſhould be uſed. On the fourth day, if he ſeems more lively and free from heat, purge him with (N°. 6.); two ounces of ſalts and one ounce of common ſalt, diſſolved in a pint of lukewarm water, with two ſpoonfuls of honey. If this does not procure four or five evacuations, repeat the clyſter the ſame day.

This mode of treatment muſt be continued without intermiſſion till the beaſt begins to eat; then he muſt have only the white drink (N° 2) and a little good fodder, or ſome rye-bread dipped in ſtale-beer, moderately ſweetened with honey or ſyrup. The exterior treatment conſiſts in the application of ſetons in the beginning of the diſtemper, at the bottom of the dewlap, and of cauteries towards the horns, between which ſome weight, *e.g.* a ſtone of a pound weight or more, wrapped up in a cloth, muſt be fixed in order to keep it ſteady. This is neceſſary to keep the head warm. But above all, the friction muſt be carefully attended to, for determining the critical efforts of nature. It would be proper alſo to evaporate vinegar in the cow-houſe, &c. and if it could be done without riſk, blowing of a few grains of gunpowder in them twice a day would be a very uſeful fumigation. If, notwithſtanding theſe aids, the beaſt be not perfectly cured in ten or twelve days, they muſt be continued without bleeding, unleſs the inflammation be very conſiderable; but if, after all, the diſtemper does not give way, the beaſt muſt be killed, buried very deep, and well covered with earth and turf, for the purpoſe of preventing the exhalation of the putrid vapours and the ſpread of the infection. The principal preſervatives from infection conſiſt in waſhing the racks, troughs, &c. and the hide of the beaſt every day, with plenty of water; and inſtead of expenſive aromatic fumigations ſometimes recommended, the uſe of fires made with the branches of green wood, with pitch thrown on it to quicken the flames and perfume the air. Common ſalt given in ſmall quantities every day to horned cattle, is reckoned an excellent preſervative, particularly in a learned diſſertation on the contagious diſtempers among horned cattle, by M. de Limborg, M.D. F.R.S. Letters, &c. on Agriculture of the Bath, &c. Society, vol. i.

EPLOYE', in *Heraldry*. An eagle eployé is what in Engliſh we more uſually call an eagle diſplayed, or a ſpread eagle. See Displayed.

EPNEUMATOSIS, from πνευματοω, *I breathe*, in *Medicine*, the ſame with expiration.

EPOBOLIA, in *Antiquity*, a fine laid upon thoſe that could not prove the indictment they had brought againſt their adverſaries.

It was ſo called, becauſe they were obliged to pay the ſixth part of the value of the thing they contended for, *viz.* an obolus out of every drachm. Some of theſe ſums were depoſited in all law-ſuits, a very few excepted, before the trial could proceed. Potter. Archæol. Græc. lib. i. cap. 21. tom. i. p. 117.

EPOCH, in *Aſtronomy*, is the mean longitude of a planet for the commencement of a given year. It is one of the principal elements of the elliptic motion. (See Element and Elliptic *Motion.*) When two obſervations of a planet are made in the mean diſtances, that is, at three and nine ſigns of mean anomaly, it is then practicable to correct, by two ſuch obſervations, both the epoch and equation of the centre. If the latter is exact, there will be no other difference between the calculation and obſervation than the epoch of the mean motion, ſince the place of the aphelion does not influence the longitudes taken at the mean diſtances; the error will, therefore, be equal in the two obſervations, for we ſuppoſe the mean motion known exactly. Thus, if the errors of the tables are found equal at three and nine ſigns of anomaly, it is a proof that the equation of the centre is exact, and that the error lies wholly in the epoch being improperly aſſumed.

EPOCHA, in *Chronology*, a term or fixed point of time, whence the ſucceeding years are numbered or accounted.

The word is εποχη, q. d. *inhibitio, repreſſio*, formed of επεχειν, *to ſuſtain, ſtop*, becauſe the epocha defines or limits a certain ſpace of time. For the difference between epocha and era; ſee Æra.

Different epochas obtain in different nations; and no wonder; for there being no aſtronomical conſideration to render one preferable to another, their conſtitution is purely arbitrary. That principally regarded among Chriſtians is, the epocha of the Nativity or Incarnation of Jeſus Chriſt; that of the Mahometans, the Hegira; that of the Jews, &c. the Creation of the World; that of the ancient Greeks, the Olympiads: that of the Romans, the Building of the City; that of the ancient Perſians and Aſſyrians, the epocha of Nabonaſſar, &c.

The doctrine and uſe of epochas are of very great extent in chronology.

To reduce the years of one epocha to thoſe of another, *i. e.* to find what year of one correſponds to a given year of another; a period of years has been invented, which, commencing before all the known epochas, is, as it were, a common receptacle of them all, called the Julian period. To this period all the epochas are reduced, *i. e.* the year of this period whereon each epocha commences is determined. All that remains, therefore, is, to add the given year of one epocha to the year of the period correſponding with its riſe; and from the ſame to ſubtract the year of the ſame period correſponding to the other epocha; the remainder is the year of that other epocha.

Epocha *of Chriſt*, or *of our Lord*, is the vulgar epocha throughout Europe, commencing from the ſuppoſed time of our Saviour's nativity, December 25, or rather according to the uſual account, from his circumciſion, that is, from the firſt of January.

Now, the year of the Julian period, wherein Chriſt was born and circumciſed, is uſually computed to be the 4713th; conſequently, the firſt year of the era of Chriſt correſponds to the year 4714 of the Julian period.

Hence, 1. If to any given year of Chriſt you add 4713, the ſum will be the year of the Julian period correſponding thereto, *E. gr.* If to the year 1809 be added 4713, the ſum 6522 is that year of the Julian period.

2. On the contrary, ſubtracting 4713 from any given year of the Julian period, the remainder is the current year of Chriſt. *E. gr.* from the year of the Julian period 6522, ſubtracting 4713, the remainder is the year of Chriſt 1809.

In effect, the epocha of our Lord ſerves not only for the computation of the years elapſed ſince the epocha commenced, but even of thoſe before it.

Now, to find the year of the Julian period correſponding to a given year before Chriſt, ſubtract the given year from 4713, the remainder is the correſpondent year required. Thus, *e. gr.* the year before Chriſt 752, is the year 3961 of the Julian period. On the contrary, ſubtracting the year of the Julian period from 4713, the remainder is the year before Chriſt.

The author of the vulgar epocha, or way of computing from Chriſt, is an abbot of Rome, one DIONYSIUS *Exiguus*, (which ſee,) by nation a Scythian, who flouriſhed under Juſtinian about the year 507, or, according to others, 527, though this Dionyſius borrowed the hint from Panodorus, an Egyptian monk. Till his time, the generality of Chriſtians computed their years either from the building of Rome, or according to the order of the emperors and conſuls, and by other ways in uſe with the people among whom they lived.

This diverſity occaſioning a great diſtraction between the churches of the Eaſt and Weſt; Dionyſius, to compoſe the ſame, firſt propoſed a new form of the year, with a new general era, which in a few years time was generally admitted.

Dionyſius began his account from the conception or incarnation, by us popularly called Lady-day, or the Annunciation; which method obtained in the dominions of Great Britain till the year 1752, before which time the Dionyſian and Engliſh epocha was the ſame; but in that year the Gregorian calendar having been admitted by act of parliament, they now reckon from the firſt of January, as they do in the other countries of Europe, except in the court of Rome, where the epocha of the incarnation ſtill obtains for the date of their bulls.

It muſt be added, that this epocha of Dionyſius is charged with a miſtake: the common opinion is, that it places our Saviour's nativity a year too late; or that he was born the winter preceding the time preſcribed by Dionyſius for his conception.

But the truth is, the fault lies on Bede, who miſinterpreted Dionyſius, and whoſe interpretation we follow, as has been ſhewn by Petavius from Dionyſius's own epiſtles; for Dionyſius began his cycle from the year 4712, but his epocha from the year 4713, wherein the vulgar era ſuppoſes Chriſt to have been incarnate.

The year, therefore, which, according to the vulgar epocha, is the firſt year of Chriſt, according to Dionyſius's era is the ſecond; ſo that the year which we call 1809, ſhould, in juſtice, be 1810, though ſome chronologers, inſtead of one year, will have the error two.

Others ſuppoſe that the Dionyſian era is four years too late; which ſuppoſition is confirmed by conſidering that our Saviour was born before the death of Herod the Great; and during the reign of Auguſtus (Matth. ii. 1. 22. Luke, ii. 1.) and according to the teſtimony of Joſephus, (lib. xvii. cap. 18.) there was an eclipſe of the moon in the time of Herod's laſt illneſs; which eclipſe appears to have happened in the year of the Julian period 4710, March 13, at Jeruſalem. Now, as our Saviour muſt have been born ſome months before Herod's death, ſince in the interval he was carried into Egypt, the lateſt time in which we can fix the true era of his birth is about the end of the 4709th year of the Julian period.

In order to aſcertain the true year of our Saviour's birth, it is neceſſary to fix the preciſe time of Herod's death. The chief opinions concerning the time of this event are three. Some think he died a little before the paſſover of A. U. 750, Julian year 42; others on Nov. 25 in that year: and others, a ſhort time before the paſſover A. U. 751. We learn from Joſephus, (De Bell. lib. ii. c. 1. Antiq. l. xvii. c. 9.) whoſe authority we cannot reject in deciding this queſtion, that Herod died but a ſhort time before one of the Jewiſh paſſovers. That Herod died a ſhort time before the paſſover A. U. 750, Julian year 42, is argued in this manner. His diſtemper had made great progreſs before the pulling down of the golden eagle at the temple. The Jewiſh rabbies excited their ſcholars to this action. News being brought that Herod was *dying* (Joſ. de Bell. l. i. c. 33. § 1.) or *dead* (Joſ. Ant. l. xvii. c. 6. § 3.) theſe rabbies were taken up and carried to Jericho, where Herod was, in a very infirm ſtate, and where they were tried and burnt to death. On that very night there was an eclipſe of the moon, which, as we have already mentioned, happened March 13th A. U. 750. From this time Herod grew worſe and worſe; ſo that he could not live long. The paſſover of this year happened on the 11th of April; and the interval between the 13th of March and 11th of April would have been ſufficient for every thing that Joſephus has related concerning Herod's illneſs; the ſettling of his affairs, the execution of Antipater, Herod's death and funeral, which are the occurrences between the eclipſe and Archelaus's coming to Jeruſalem at the paſſover.

Beſides, from circumſtances related by Joſephus concerning Archelaus, one would be apt to conclude, that he reigned nine years complete, and that the 10th year was current when he was baniſhed. Dio (l. lv. p. 567.) places Archelaus's baniſhment in the 759th year of Rome. If Herod did not die, as ſome imagine, till the beginning of A. U. 751, the 9th year of Archelaus's reign could not be completed in the 759th year of Rome. But if Herod be ſuppoſed to have died in the beginning of A. U. 760, Joſephus and Dio agree. Moreover, Joſephus ſays, that Cyrenius ſeized Archelaus's eſtate, and finiſhed the aſſeſſment in Judea in the 37th year after the defeat of Antony at Actium by Cæſar Auguſtus. The victory at Actium was obtained Sept. 2, A. U. 723; therefore the 37th year from it begins Sept. 2, A. U. 759, and ends Sept. 2, 760. Suppoſing then that Herod died in the beginning of A. U. 750, there is in this particular alſo a very good harmony between Joſephus and Dio. Beſides, Joſephus informs us (Ant. l. xiv. c. 29.) that Herod was appointed king by the Roman ſenate A. U. 714. *i. e.* 40 years before the vulgar era. The ſame hiſtorian obſerves, that he died in the 37th year of this reign, and 34th after the death of Antigonus, *viz.* in the 42d Julian year (Antiq. l. xvii. 10.) If to 713 we add 37, the ſum will be 750, the year of Rome in which this prince died.

The opinion, adopted by other learned men, that Herod died a ſhort time before the paſſover A. U. 751, labours under ſeveral great difficulties, which are pointed out by Dr. Lardner (ubi infra). Upon the whole it appears, that Herod did not die before the year 750, nor ſurvive the year 751, and that he died a ſhort time before the Jewiſh paſſover of one of theſe years. It follows, that if Herod died in 750, he died three years and nine months before the vulgar Chriſtian era, which commences January 1, A. U. 754; if at the time above-mentioned, in the year 751, then he died about two years and nine months before the ſaid era. "Which is the truth," ſays Dr. Lardner, with his uſual diffidence and modeſty, "I am not able to determine." Accordingly he ſays, that "if Herod died in March A. U. 750, I ſhould be inclined to place the nativity of Jeſus in September or October, A. U. 748; if Herod died in March 751, then the nativity of Jeſus might very well be placed in September or October 749." The birth of Jeſus muſt be dated about a year and five or ſix months before the death of Herod, *i. e.* before the latter end of the year of Rome 748 or 749, *i. e.* 4708 or 4709 of the Julian period; but for reaſons already aſſigned, the latter date is the moſt probable.

We ſhall here add, that an objection has been urged againſt the 15th year of the reign of Tiberius, compared with the age of Jeſus at his baptiſm. (Luke, iii. 1, 2. 23.) If Jeſus, it is ſaid, was born above a year, much more, if above two years before Herod's death, then the age of 30 years, here aſcribed to him at his baptiſm, is abſolutely inconſiſtent with the notes of time mentioned at the commencement of John the Baptiſt's miniſtry; even allowing, that *the word of God came to John* in the very beginning of the *15th year of Tiberius*, and that Jeſus was baptized a few months after. Dr. Lardner obſerves, that the true meaning of theſe words, *Jeſus himſelf began to be about 30 years of age*, is not that he then *entered* the 30th year of his age, but that Jeſus was about 30 years of age when he began his miniſtry. This, he ſays, is now the general opinion of learned men; ſo the Greek word of this text is uſed by St. Luke in other places. The objection is thus ſtated: Auguſtus died, and Tiberius ſucceeded him the 19th of Auguſt, A. U. 767, Julian year 59, A. D. 14. Therefore the 15th of Tiberius began the 19th Aug. A. U. 781, A. D. 28. Herod died before the paſſover, in A. U. 751, Jul. year 43. If then John the Baptiſt began to preach in the beginning of the 15th of Tiberius, in the latter end of A. U. 781, and Jeſus be ſuppoſed to have been baptized by John a few months after, on the 6th of January of the year following, *viz.* A. U. 782, Jeſus muſt have been in the 32d year of his life, if Herod died in the ſpring, *viz.* A. U. 751, and if Jeſus was born the 25th of December preceding, *viz.* A. U. 750. But if Herod died A. U. 750, and Jeſus was born the 25th December before, *viz.* A. U. 749, then he would be at his baptiſm in the 33d year of his age. But it may be made to appear in ſeveral ways, that Jeſus was born above a year, probably above two years before Herod died. Dr. Lardner has ſtated this objection in its full force; and detailed ſeveral circumſtances that tend to obviate it. From ſome of them he infers, that there is no neceſſity of placing the birth of Jeſus above a year and ſix months before the death of Herod, as we have already ſtated. As it is moſt probable that Herod died A. U. 750, we may be diſpoſed, from other circumſtances alleged by this accurate and impartial writer, to place the nativity of Jeſus in September or October A. U. 748. The latter part of the ſummer, or the autumn ſeaſon, ſeems to be the moſt likely time of the year for the birth of Jeſus; nor is there any particular reaſon that ſhould determine us to the 25th of December. The very depth of winter was not a very proper ſeaſon for a ſurvey and aſſeſſment, when people are to enter themſelves according to their tribes or families; the autumn, when harveſt and vintage are over, would be a time of general leiſure. When Jeſus was born in Bethlehem, *there were in the ſame country ſhepherds abiding in the field, keeping watch over their flocks by night*, (Luke, ii. 8.) This circumſtance is not very favourable to the ſuppoſition, that Jeſus was born the 25th of December; and we are at liberty to place it in autumn, a more likely ſeaſon. (See CHRISTMAS.) It is not improbable then, that Jeſus might be born ſome time between the middle of Auguſt and the middle of November. Cyrenius, we may ſuppoſe, came into Judea at the time, or ſoon after the time, that Varus became governor of Syria (before Sept. A. U. 748), and publiſhed the decree of Auguſtus, requiring all people to enter themſelves, their dependents, and eſtates. This aſſeſſment could well be made in a country of ſuch ſmall extent as Judea in two or three months; and the ſhort time appointed for this work may be inferred from the peculiar circumſtances of Cyrenius, who wiſhed to haſten back to Rome, and alſo from St. Luke's hiſtory of it. Upon the whole, we may conclude, that about a year and ſix or ſeven months before the death of Herod, ſoon after the arrival of Varus in the province of Syria, in Auguſt or September A. U. 748 or 749, Julian year 40 or 41, Cyrenius (or ſome other perſon of eminence) came into Judea, an aſſeſſment was made there, and in the time of it, Jeſus was born at Bethlehem, in the month of September or October. In order, however, to ſettle ſatisfactorily the *15th year of the reign of Tiberius*, we ſhould conſider that the commencement of his reign may be computed from a different period than that of his ſole empire, after the death of Auguſtus. In fact, it appears, that there were two different dates of the beginning of Tiberius's reign; one from the time of his being made colleague with Auguſtus, and the other from his ſole empire, after the death of Auguſtus. Many learned writers are of opinion, that St. Luke intends the former of theſe two computations, referring to a period two years before the death of Auguſtus, *viz.* in A. U. 765, when Piſo was præfect of Rome, Tiberius being prince. Archbiſhop Uſher and Prideaux place the beginning of this government of Tiberius in this year. This epoch of Tiberius's empire was followed for ſome time by ſome perſons, in the provinces at leaſt; but it is not ſo certain, when this pro-conſular empire began, whether about two years, or about three years before Auguſtus died. If Tiberius's proconſular empire began about three years before Auguſtus died, on the 28th of Auguſt A. U. 764, A. D. 11, then this 15th of Tiberius's reign (according to this computation of it) began Auguſt 28th, A. U. 778, A. D. 25. Suppoſing that John the Baptiſt began his miniſtry November following, in the ſame year, and that Jeſus was baptized by him the 6th of Jan. following, in A. U. 779, A. D. 26; then upon the ſuppoſition that Jeſus was born in Sept. A. U. 748, he would be at his baptiſm 30 years of age, and ſome months more. If Tiberius's proconſular empire commenced about two years before the death of Auguſtus, in A. U. 765, A. D. 12, then the 15th year of the reign of Tiberius began in A. U. 779, A. D. 26. And ſuppoſing that John the Baptiſt began his miniſtry in November of that year, and that Jeſus was baptized by him the 6th of January following, A. U. 780, A. D. 27, then, upon the ſuppoſition that Jeſus was born in September, A. U. 749, he would be at the time of his baptiſm 30 years of age, and ſome months more; or, if born A. U. 748, he would be ſomewhat more than 31 years of age. Again, if John the Baptiſt began his miniſtry in the 15th of Tiberius, A. U. 778, A. D. 25, according to the firſt ſtatement, but did not baptize Jeſus till the 6th of January, A. U. 780, A. D. 27, after he had preached ſomewhat above a year, then Jeſus would be at his baptiſm 30 years of age and odd months, if he was born A. U. 749; 31 years of age and ſome odd months, if born the latter end of the year 748. Such will be the reſult, if we take thoſe dates of theſe events, which appear moſt favourable to St. Luke; ſince it is not abſolutely certain when Herod died, or when Tiberius's proconſular empire began. But if we allow on each hand the dates leaſt favourable to St. Luke's numbers, *viz.* that Jeſus was born A. U. 748, and that he was not baptized till January A. U. 780, A. D. 27; yet even then Jeſus would be little more than 31 years of age; at which time a perſon may be ſaid very properly to be ABOUT *thirty years of age.*

The queſtion of our Lord's nativity and age at his baptiſm is amply diſcuſſed, and the difficulties which it involves accurately and impartially examined, by Dr. Lardner in his "Credibility, &c." See his Works, vol. i. See alſo Playfair's Syſtem of Chronology, p. 49, &c.

Learned men have differed in opinion concerning the preciſe time of the death of Chriſt. Some have referred this event to the 29th year of the vulgar era; others to the 31ſt; and not a few to the 33d. Playfair (with whom Blair agrees) inclines to adopt the laſt of theſe dates, for the following reaſons. 1. There is no other year beſides the 33d of the vulgar era, 78th Julian year, 4746th of the Julian period, A. U. 786, to which this event can be properly referred; for Jeſus Chriſt went to eat the paſſover with his diſciples on the evening of the 14th of the firſt month, and was crucified on the day following, *viz.* on Friday, April 3d, the 16th day of the paſchal moon, according to the true, and the 15th, according to the Jewiſh computation. 2. The 70 weeks of Daniel, which began in the 20th year of Artaxerxes Longimanus, and ended in J. P. 4746, when Meſſiah was cut off. 3. Phlegon, the freedman of Adrian, and eſteemed as an exact computer of the Olympiads, obſerved "that in the 4th year of the 202d Olympiad, there was a miraculous darkneſs; for at the ſixth hour of the day came on night, inſomuch that the ſtars of heaven were ſeen. At the ſame time, there was alſo a great earthquake in Bithynia, which threw down part of the city of Nice." (Compare this account with Matth. xxvii. 45. and Luke, xxiii. 45.) The 4th year of the 202d Olympiad anſwers to the firſt ſix months of the 33d year of our vulgar era, and to the 19th of the reign of Tiberius. Concerning the teſtimony of Phlegon; ſee PHLEGON. 4. When Chriſt ſuffered, Pontius Pilate was governor of Paleſtine (Tacit. l. xv. Joſeph. Antiq. l. xviii. c. 5.); Herod Antipas was tetrarch of Galilee (Luke, xxiii. 6. Joſeph. Antiq. l. xix. c. 7.); and Caiaphas was high-prieſt among the Jews (John, xi. 49. Luke, iii. 2. and Acts, iv. 6.) (See CAIAPHAS.) From theſe and other characters it appears, ſays Playfair, that Jeſus Chriſt lived about 36 years, 3 months, 9 days, and 15 hours, if we reckon (according to the generally received opinion concerning the month and day of his nativity) from midnight of December 25th, of the 42d Julian year commencing, to April 3d and 3 in the afternoon, of the 78th Julian year. His reſurrection took place on Sunday April 5th, and his aſcenſion on Thurſday May 14th.

To the vulgar era of our Lord's nativity, as a ſure fixed point, chronologers have been accuſtomed to reduce all the other epochas, though there is not one of them but what is controverted; ſo much uncertainty there is in the doctrine of time. We ſhall exhibit them as reduced to the Julian period.

EPOCHA *of the Creation, Orbis Conditi,* according to the computation of the Jews, called alſo the Jewiſh epocha, is the year of the Julian period 953, anſwering to the year before Chriſt 3761, and commencing on the ſeventh day of October. Hence ſubtracting 952 years from any given year of the Julian period, the remainder is the year of the Jewiſh epocha correſponding to it. Thus, *e. gr.* the year 1809 being the 6522d year of the Julian period, it is the 5570th year of the Jewiſh epocha, or ſince the creation of the world.

This epocha is ſtill in uſe among the Jews.

The EPOCHA *of the Creation,* uſed by the Greek hiſtorians, is the year before the Julian period, 787, anſwering to the year before Chriſt 5500.

Hence, to any given year of the Julian period, adding 787, the ſum gives the year of this epocha. *E. gr.* 1809 being the 6522d year of the Julian period, 7309 is that year of this epocha, or the year of the world, according to this computation.

The author of this epocha is Julius Africanus, who collected it from the hiſtorians: but when it came to be admitted into civil uſe, 8 years were added to it, that ſo every year thereof divided by 15 might exhibit the indiction, which the eaſtern emperors uſed in their charters and diplomas.

The epocha of the creation uſed by the latter Greeks and Ruſſians is the year 795 before the Julian period, or the year 5508 before Chriſt, commencing from the firſt day of September. Though the Ruſſians, having lately admitted the Julian calendar, begin their year from the firſt of January.

Hence, adding 795 to the year of the Julian period, the ſum gives the year of this epocha. Thus, *e. gr.* the Julian period of the year 1809 being 6522, that year of this epocha, *i. e.* the years from the creation on this footing are 7317. Again, from that year 7317 ſubtracting 5508, the remainder is the year of the common era 1809. This era was uſed by the emperors of the Eaſt in their diplomata, &c. and thence alſo called the "civil era of the Greeks." In reality, it is the ſame with the epocha of the Conſtantinopolitan period; whence ſome call it the "epocha of the period of Conſtantinople."

The Alexandrian EPOCHA *of the Creation* is the year 780 before the Julian period, anſwering to the year before Chriſt 5493, and commencing on the 29th day of Auguſt.

Hence, adding 5493 to the year of Chriſt 1809, the ſum 7302 gives that year of this epocha, or years elapſed ſince the creation, according to this computation.

This epocha was firſt concerted by Panodorus, a monk of Egypt, to facilitate the computation of Eaſter; whence ſome call it the "Greek eccleſiaſtical epocha."

The Euſebian EPOCHA *of the Creation,* is the year of the Julian period 486, anſwering to the year before Chriſt 4228, and commencing in autumn.

Hence, ſubtracting 486 from the year 6522 of the Julian period, or adding 4228 to the year of Chriſt 1809, the reſult 6036 will be that year of this epocha.

This epocha is uſed in Euſebius's Chronicon, and the Roman Martyrology.

The EPOCHA *of the Creation,* according to Mr. Bedford and Mr. Kennedy, is the year of the Julian period 706, anſwering to the year before Chriſt 4007.

The EPOCHA *of the Creation,* according to archbiſhop Uſher, adopted in Blair's tables, is the year of the Julian period 710, correſponding to the year before Chriſt 4004; but it muſt be allowed, that all the epochs of the creation are uncertain. See Strauchius's Brev. Chron. by Sault. p. 152, &c. See chronological table under the article CHRONOLOGY.

EPOCHA *of the Univerſal Deluge,* in the year of the creation 1656, and according to the different methods of computation; ſee the table under CHRONOLOGY, and ANTEDILUVIAN.

EPOCH *of the Olympiads,* is the year of the Julian period 3938, anſwering to the year 776 before Chriſt, commencing at the full moon next the ſummer ſolſtice, and each Olympiad containing four years.

This epocha is very famous in ancient hiſtory; it was uſed principally by the Greeks, and had its origin from the Olympic games, which were celebrated at the beginning of every fifth year. See the table above cited, and Olympic *Games*.

Epocha *of the Building of Rome*, or *Urbis Conditæ, U. C.* is the year of the Julian period 3961, according to Varro; or 3962, according to the Faſti Capitolini, anſwering to the years before Chriſt 753 or 752, and beginning on the 20th of April. Hence, if the years of this epocha be fewer than 754, ſubtracting them from 754 or 753, you have the year before Chriſt; and, on the contrary, if they be more than 754, you muſt ſubtract 754 to have the year of Chriſt, and add the year of Chriſt to 754 to have the year of this epocha, or the time ſince the building of Rome. Thus, *e. gr.* the year 1809, according to Varro, is the year of Rome 2563.

The ſentiments of the earlieſt Roman writers, with reſpect to this epoch, are various; Polybius refers it to the year B. C. 751. Cato, whoſe opinion is adopted by Solinus, Euſebius, Dionyſius Halic. &c. places it one year earlier. Fabius Pictor, who flouriſhed in the time of the firſt Punic war, and who is ſtyled by Dion. Hal. an accurate writer, brings it down to the 29th year of the olympiads, *i. e.* 747 B. C. Diodorus Siculus adopts this opinion. Sir Iſaac Newton, on the teſtimony of ſome later Roman writers, obſerves that Rome was built in the 15th age after the deſtruction of Troy, that is, after the 14 kings who reigned in Alba. Allowing 21 years to the reign of every king, and computing from the year B. C. 904, when he ſuppoſes Troy to have been taken, he brings forward this epoch to the 38th olympiad, *i. e.* 627 B. C. The date of Varro has been adopted by the Roman emperors in their proclamations, by Plutarch, Tacitus, Dion, Gellius, Cenſorinus, Onuphrius, Baronius, and by moſt modern chronologers.

Epocha *of Nabonaſſar*, is the year of the Julian period 3967, anſwering to the year before Chriſt 747, commencing the 26th day of February of the Julian year at mid-day. The ſolar cycle was 19, the lunar 15, and the cycle of indiction 7.

This era takes it denomination from its inſtitutor Nabonaſſar king of Babylon, and is that uſed by Hipparchus, by Ptolemy in his Aſtronomical Obſervations, by Cenſorinus, and others.

This epoch is of ſingular ſervice in chronology, as it ſerves to connect and adjuſt all other epochas. The form of this era, which included a period of 424 Egyptian years from the commencement of Nabonaſſar's reign to the death of Alexander the Great, and which was thence carried down to the reign of Antoninus Pius, is ſingular. Every year conſiſts of 365 days, and is divided into 12 months. Every month contains 30 days; five intercalary days are added to theſe months, and the ſum compoſes the quantity of the Nabonaſſarean year. In every four Julian years, the correſponding four years of this era were evidently deficient by one day; therefore the beginning of the Nabonaſſarean years muſt have moved retrogradely; and in the ſpace of 1460 Julian years, muſt have gone through every day of the year. Whence it appears, that 1460 Julian are equal to 1461 Nabonaſſarean years. If the firſt year of the era of Nabonaſſar began on Wedneſday, Feb. 26th, the ſecond and third years muſt have begun on the ſame day; becauſe theſe two years contain 365 days each in the Julian, as well as in the Egyptian calendars. The following year, *i. e.* 744 B. C. being a biſſextile, one day was added to the Julian year, conſequently the Nabonaſſarean year began on Feb. 25th in this and the three ſucceeding years. In the year 740 B. C. it began on February the 24th; in 736 B. C. on February the 23d, &c. The firſt day of any year of the Nabonaſſarean era may be found by the following general rule.

Divide the given year by 4 (becauſe in 4 years the Nabonaſſarean year anticipates the Julian by one day), and the quotient will be the number of days of anticipation, or of the omitted leap-days. If the quotient be leſs than 57 (the number of days from January 1ſt to February 26th), let it be ſubtracted. If the quotient exceeds 57, ſubtract it from 422, *i. e.* from 57 + the number of days in one Julian year, and the remainder will be the day of the Julian year, reckoned from January 1ſt, which is the Thoth, or firſt day of the year following the given one; (Thoth being the name of the month, which in the firſt year of this era correſponded to Feb. 26th of the Julian year.) From the day found, ſubtract 1, and the remainder will be the number of the day required.

E. G. On what day of the Julian year did the Thoth of the Nab. era 230 fall? Divide 230 by 4, and the quotient 57, ſubtracted from 422, leaves a remainder of 365. This ſhews that the Thoth of N. E. 231ſt falls on December 31ſt, or on the 365th day of the Julian year: ſubtract 1, and the remainder 364, or December 30th, will be the day required.

Epocha, or *Era of Conſtantinople*, is ſuppoſed to have commenced before the creation of the world; for the 5509th year of it anſwers to the 1ſt of the vulgar Chriſtian era. It was adopted by the Greek church and empire, all the public acts of which are ſtill dated by it; and the Muſcovites computed by it until the reign of Peter the Great. Thoſe who reckon by it make uſe of civil and eccleſiaſtical years. The former begin with the month of September, and the latter, ſometimes with the 21ſt of March, and ſometimes with the 1ſt of April.

Epoch *of New Rome*, or *Conſtantinople*, is uſually computed from the time of the conſecration of the city. Accordingly the firſt year of this era was the 25th of the reign of Conſtantine, A. M. 5838, as the modern Greeks eſtimate the era of the creation, Julian period 5043. Thus directed, the conſecration of the city is fixed in the 330th year of the vulgar era, on the 11th of May.

Epocha, *Diocleſian*, or *Epocha of Martyrs*, is the year of the Julian period 4997, anſwering to the year of Chriſt 284, called the "era of martyrs," from the great number of Chriſtians who ſuffered martrydom under the reign of that emperor.

The Abyſſinians, among whom it is ſtill uſed in all eccleſiaſtical computations, call it the "year of grace;" though they do not reckon their years in a continued ſeries from this epocha. But when the Dionyſian period of 534 years is expired, they begin their computation afreſh from 1, 2, &c.

Epocha *of the Hegira*, or *Mahometan Epocha*, is the year of the Julian period 5335, anſwering to the year of Chriſt 622. It commences on Friday the 16th of July, the day of Mahomet's flight from Mecca to Medina.

This epocha is uſed by the Turks and Arabs, and even all who profeſs the Mahometan faith. It was firſt introduced by Omar, the third emperor of the Turks. The aſtronomers Alfraganus, Albategnius, Alphonſus, and Ulugh Beigh, refer Mahomet's flight to the 15th of July; but all the people who uſe the epocha agree to fix it on the 16th. See Hegira.

Epocha *of the Seleucidæ*, which is uſed by the Macedonians, is the year of the Julian period 4402, anſwering to the year before Chriſt 312. This is reckoned from the time when Seleucus, one of the generals of Alexander's army, took Babylon and aſcended the Aſiatic throne.

This era is ſometimes called the Grecian era, and the era of Principalities, in reference to the diviſion of Alexander's empire. The Arabians ſtyle it "Tarik Dhilcarnaim," *i. e.* the era of Contracts, and the Greeks denominate it the Horned era. Thoſe who uſe it reckon ſometimes by Nabonaſſarean years, and ſometimes by Julian, compoſed of Roman months, to which Syrian names have been affixed. Its commencement has been variouſly ſtated, ſome date it on Tueſday March 13th. The Greeks in Syria reckon from a month correſponding to our September. Albategni, and others, reckon from the 1ſt of October. In the firſt book of Maccabees the year is ſaid to have began in Niſan, or the firſt month of ſpring; but in the ſecond book, and in other Jewiſh hiſtories, its beginning is dated in Tizri, which is the firſt month of autumn. See SELEUCIDÆ.

EPOCHA, *Perſian*, or *Yezdegerdic*, is the year of the Julian period 5345, anſwering to the year of Chriſt 632, and commencing on the 16th of June.

This epocha is taken from the death of Yezdegerdis, the laſt king of Perſia, ſlain in battle by the Saracens. See *Perſian* CALENDAR.

EPOCHA, or *Era of the Perſian Monarchy*, is referred by almoſt all ancient hiſtorians to the 1ſt year of the 55th olympiad, *i. e.* 560 B. C. Of this opinion are Diodorus Siculus, Thallus, Caſtor, Polybius, Phlegon, and Euſebius. From the beginning of the Nabonaſſarean era to the firſt year of the reign of Cyrus over Babylon, Ptolemy reckons 209 years. If this number be ſubtracted from 747, the remainder 538 will be the Babylonian epoch of Cyrus; and the monarchy ſtood, according to Agathias, from the firſt year of Cyrus 228 years. That this was its duration is evident from a paſſage of Plutarch (in Vit. Alex.) which mentions an eclipſe of the moon that happened 11 days before the laſt battle between Darius and Alexander, in the month Boedromion. This eclipſe is found, by calculation, to have coincided with the 446th olympic year, Sept. 20. If, therefore, the difference be computed between the 550th olympiad, *i. e.* the 217th olympian year, when the Perſian empire began, and the 446th, when it ended, it will appear to have flouriſhed 228 or 229 years.

EPOCHA, *Gelalæan*, called alſo *Royal Epocha*, and *Epocha of the Sultans*, began in the year of the Julian period 5787, A.D. 1074, on the 14th day of March, at the time of the equinox, and was eſtabliſhed for the convenience of finding the vernal equinox, at which time the Perſians celebrated their great feaſt, called *Neuruz*. See *Perſian* CALENDAR.

EPOCHA *of the eſtabliſhment of the Roman Conſular dignity*. The republican form of government in Rome owed its origin to the tyranny of Tarquin the ſeventh king; in conſequence of which the ſovereign authority was divided, and two magiſtrates were elected under the denomination of conſuls. The conſular dignity was conferred on Brutus and Collatinus, 244 years after the building of the city. The names of the conſuls were regiſtered in the calendars until A. D. 541; and in the 15th year of Juſtinian the order was aboliſhed. See CONSUL.

EPOCHA, *Julian*, or *Epocha of Julian years*, is the year of the Julian period 4668, anſwering to the year before Chriſt 46.

This epocha had its origin from the year of the reformation of the calendar under Julius Cæſar, called the "year of confuſion."

EPOCHA, *Gregorian*. See GREGORIAN.

EPOCHA, *Spaniſh*, is the year of the Julian period 4676, anſwering to the year before Chriſt 38.

This era commenced at the time of the ſecond diviſion of the Roman provinces among the Triumviri, and is reckoned from the 1ſt of January in the year 38 B. C. ſo that the firſt year of the Chriſtian coincides with the 39th year of the Spaniſh era. The moſt famous ſynods of Spain and Africa have been diſtinguiſhed and deſcribed according to the computation of this era; but by a decree of the council of Tarragon, A. D. 1180, the Chriſtian era was ſubſtituted in its room, though it continued in uſe till the year 1383. The Portugueſe were the laſt people who computed by this era, and they gave it up A. D. 1415 or 1422. See ÆRA.

EPOCHA, *Actiac*, or *Actian*, is the year of the Julian period 4684, anſwering to the year before Chriſt 30, commencing in Egypt on the 29th day of Auguſt, and on the 1ſt of September among the Greeks of Antioch; but among the Romans on the 1ſt of January in the year of Rome 724.

EPOCHA *of the Reformation*. See REFORMATION.

For other epochas or eras, and the dates of remarkable events, ſee the table under CHRONOLOGY.

EPOCHETEUSIS, from εποχετευω, *I draw through a canal*, of οχετος, *canal*, a word uſed by Hippocrates, and others of the old writers in *Medicine*, to expreſs the derivation of the blood, or juices, from one part to another.

EPODE, Επωδος, in *Lyric Poetry*, the third or laſt part of the ode; the ancient ode, or ſong being divided into ſtrophe, antiſtrophe, and epode.

According to its moſt common acceptation, it ſignified a number of Lyric verſes of different conſtruction, compriſed in a ſingle ſtanza; and it was ſung by the prieſts, ſtanding ſtill before the altar, after all the turns and returns of the ſtrophe and antiſtrophe. The invention of epodes is aſcribed to Archilochus.

The epode was not confined to any preciſe number, or kind of verſes, as the ſtrophe and antiſtrophe were: but when the ode contained ſeveral epodes, ſtrophes, &c. they were all alike.

As the word epode, then, properly ſignifies the end of the ſong; and as in odes, what they called the epode finiſhed the ſinging, it became cuſtomary, as M. Dacier ſhews, for any little verſe which, being put after another, cloſed the period, and finiſhed the ſenſe which had been ſuſpended in the firſt verſe, to be called epode, επωδος.

And hence it is, that the ſixth book of Horace's Odes is entitled "Liber Epodon, Book of epodes," becauſe the verſes thereof are all alternately long and ſhort; and the ſhort one, generally, though not always, cloſes the ſenſe of the long one. The name of epode was likewiſe given to a ſmall Lyric poem, compoſed of trimeters or iambics, of ſix feet, and dimeters of four feet alternately. Of this kind were the epodes of Archilochus, mentioned by Plutarch. But the ſignification of the word is extended ſtill farther; epode being become a general name for all kinds of ſhort verſes, that follow one or more long ones; and in this ſenſe, a pentameter is an epode, after an hexameter, which in reſpect thereof is a pro-ode.

EPODOS, from επι, and ωδη, *ſong*, in *Medicine*, a word uſed to expreſs the curing of diſeaſes by incantation.

EPOICODOMESIS, from εποικοδομεω, *I build upon*, in *Rhetoric*, is ſometimes uſed for what is otherwiſe called climax.

EPOISSES, in *Geography*, a ſmall town of France, in the department of the Côte d'Or, 9 miles W. of Semur.

EPOMIS, Επωμις, in *Anatomy*, the upper part of the ſhoulder, reaching up to the neck.

The word is Greek, επωμις, which primarily ſignifies a ſhort cloak or mantle made to cover the ſhoulders.

Some authors apply the word epomis to the upper part of the

the os humeri; but the ancient Greek phyſicians only uſe it for the muſcular, or fleſhy part, placed as above mentioned. See Deltoides.

EPOMPHALION, from επι, *upon*, and ομφαλος, *navel*, any medicine which purges, on being applied to the navel.

EPOPOEIA, Εποποιια, in *Poetry*, the hiſtory, action, or fable, that makes the ſubject of an epic poem.

The word is derived from the Greek επος, *carmen*, *verſe*, and ποιεω, *facio*, *I make*.

In the common uſe of the word, however, epopoeia is the ſame with epos, or epic poem itſelf: in which ſenſe it is defined a diſcourſe invented with art, or a fable agreeably imitated from ſome important action, and related in verſe, in a probable and ſurpriſing manner; with a view to form the manners, &c. See Epic *Poem*.

EPOPS, in *Ornithology*, a name by which ſome of the ancient writers have called the bird we call the upupa, or hoopoe. See Upupa, of which it is a ſpecies.

EPORA, in *Ancient Geography*, a town of Spain, 28 miles from Caſtulon, according to the Itinerary of Antonine. Pliny calls it Ripepora. It is thought to be *Montoro* in the dioceſe of Cordova. M. D'Anville places it on the river Bœtis, in Bœtica, N. E. of Corduba.

EPOREDIA, Ivrée a town of Gallia Tranſpadana, ſituated towards the weſt, on the Doria Major.

EPOTIDES, in the *Ancient Ship-Building*, two large thick pieces of wood on each ſide of the prow of a galley, which reſembled two ears, whence they had their name.

The epotides were chiefly deſigned to ward off the blows of the roſtra of the enemies' veſſels.

EPPHA, or Epha, in *Ancient Geography*, a country of Arabia, in the vicinity of the Midianites.

EPPING, in *Geography*, a market town in the hundred of Waltham, in the county of Eſſex, England, is irregularly built, and conſiſts of two parts or aſſemblages of houſes; one round the church, called Epping Upland; the other, nearly a mile and a half ſouth-eaſt from the church, called Epping Street. The latter is by far the largeſt, and conſiſts of one wide ſtreet, nearly a mile in length, ſituated on the high road from London to Newmarket, on a ridge of hills extending to a conſiderable diſtance north and ſouth. Here a market is held on Fridays: the chief commodities expoſed for ſale, are butter and poultry, which are chiefly purchaſed for the uſe of the metropolis. At the weſt end of the ſtreet is a ſmall new chapel: and near the middle are the ſhambles. The inns and public houſes are numerous. Epping is 17 miles from London; contains, in both diviſions, 315 houſes, inhabited by 1726 perſons; it has two annual fairs.

Epping *Foreſt*, is an extenſive tract of good woodland, deriving its preſent name from the town, but was formerly called Waltham Foreſt, and in very remote ages the Foreſt of Eſſex. Since it obtained the latter appellation, it has, however, been greatly curtailed, many thouſand acres having been grubbed up, and the land cultivated. This foreſt is under the juriſdiction of a lord warden and four verderers: the wardenſhip is hereditary in the family of ſir James Tilney Long, bart.: the verderers are elected by the freeholders of the county, and retain their offices during life. The foreſt rights are as various as the tenures of the different manors that ſurround it. In this foreſt, though ſo near to London, wild ſtags are yet found; and a ſtag is annually turned out on Eaſter Monday, under an eſtabliſhment patronized by the principal merchants of the city. The hunt is well ſupported: the kennel for the hounds, and the building belonging to the hunt, have been lately erected at the expence of ſeveral thouſand pounds.

At a ſmall diſtance to the ſouth-eaſt is Hainault Foreſt, famous through many centuries for a venerable tree, called Fairlop Oak, which is remarkable for its ſize, and alſo for an annual fair held on the firſt Friday in July under its branches, which overſpread an area nearly 300 feet in circumference: the ſtem, which is rough and irregular, meaſures 36 feet in girth. Morant's Hiſtory of Eſſex. Beauties of England and Wales, vol. v.

Epping, a town of Germany, in the archduchy of Auſtria; 4 miles S. of Aigen.

Epping, a poſt town of America, in Rockingham county, New Hampſhire, taken from the N. W. part of Exeter, and incorporated, in 1741. It contains 1121 inhabitants, and lies 6 miles N. W. of Exeter and 23 W. of Portſmouth.

EPPINGEN, a ſmall town of the kingdom of Bavaria, in the palatinate on the river Elſatz, 21 miles N. E. of Philipſburg, and 18 miles N.W. of Heilbrun. N. lat. 49° 12′.

EPROUVETTE, is a machine, of which there are ſeveral varieties, uſed for proving the ſtrength of gun-powder. The principle of this invention, in whatever form it may be applied, is to aſcertain how far a certain meaſure or weight of gun-powder is capable of overcoming the reſiſtance either of a certain weight, or of a ſpring, whoſe preſſure againſt the exploſion is computed. The former is evidently the moſt regular, and, conſequently, the beſt adapted to military purpoſes, wherein the ſtrength of the powder is often of the greateſt moment, not only on account of the advantages gained by the greateſt concentration of force, but becauſe in the mortar and howitzer practice it is neceſſary to have a very accurate knowledge of the powers of expanſion in the powder when ignited; by which means ſhells may be thrown, with the greateſt preciſion, to any intended diſtance; whence the exploſion takes the greateſt poſſible effect.

In our arſenals, an eight inch mortar is ordinarily employed as an eprouvette: being charged with two ounces of powder, and an iron ball of ſixty-four pounds, the latter ſhould be projected at leaſt 150 feet; the elevation of the piece being 45°, and the bed being placed perfectly horizontal. We conſider this to be a fair ſtandard; though ſome powder made from the beſt materials, and freſh from the mill will ſometimes exceed even 180 feet; while, on the other hand, weak powder, that is, ſuch as has not been kept very dry, or that has been re-ſtored, will rarely make a range equal to 120, and generally not exceeding even 110 feet.

The above mode of proof relates to cannon-powder; that intended for the uſe of muſketry is aſcertained by an eprouvette of a different deſcription; namely, a muſket barrel, of which the interior is highly poliſhed. This ſhould, with a charge of only four drachms, impel a ſteel ball through fifteen wet elm boards, each a quarter of an inch in thickneſs, and placed at ¾ of an inch aſunder; the firſt being 39 feet and 10 inches diſtant from the muzzle of the barrel. We muſt confeſs this exact number of inches in the diſtance, appears to be more faſtidious than neceſſary, for we are apt to believe, that, in experiments of this nature, the odd two inches, neceſſary to complete the fortieth foot, would by no means derange the proceſs.

The French eprouvette for cannon powder comes very cloſe to our's, they uſing a braſs ball of 60lb. (French weight) whoſe diameter is 7 inches and 9 points, or ¾ of a line, (French meaſure) with one line of windage, (or ſpace between the ſhot and the ſides of the bore.) The chamber holds preciſely three ounces; which quantity of their beſt powder will throw the ball full 180 yards; their re-ſtored powder throwing it about 160 yards. But Monſ. Lombard's bard's experiments give a reſult of 250 yards, with the powder now manufactured at the French mills; the eprouvette being always elevated to 45°.

Fine powder is ſometimes tried by means of a ſmall machine reſembling a piſtol, of which the barrel is very ſubſtantial, and the bore not more than the eighth of an inch in diameter. Over the barrel is a circular plate, acted upon ſtrongly by a ſpring, which offers conſiderable reſiſtance to the revolution cauſed therein, by the action of the powder on a projection which ſhuts down cloſe upon the muzzle. The bore being filled with powder, and the wheel, or plate, turned ſo that its projection cloſes the muzzle, the exploſion will, in proportion to its force, throw up the projection, and cauſe the wheel to revolve: the power of the powder is ſuppoſed to be aſcertained by means of figures on the circumference, which indicate how much the wheel has been thrown round.

But ſuch a machine cannot poſſibly give a correct ſtandard; it being ſo ſubject to variation; as is alſo that contrivance which cauſes the powder to act underneath the hammer of a piſtol lock. The pan being filled, the powder ſhould have force enough to throw the hammer back. We need not comment on the uncertainty of ſuch an eſtimate.

EPSOM, or Ebbesham, in *Geography*, a pariſh and formerly a market town in the hundred of Copthorpe, Surrey, England, is fifteen miles S.E. from London. In the year 1800 it contained 414 houſes, and 2404 inhabitants. The houſes are diſpoſed chiefly on two ſides of a long wide ſtreet, or public road, and are ſituated on the weſt ſide of Banſtead Downs. Theſe are diſtinguiſhed for their fine ſweet verdure, which is moſtly grazed by ſheep; and the Banſtead mutton is much eſteemed for its flavour. On theſe downs are annual horſe-races, which are much frequented by gamblers and ſharpers, from the metropolis. The church, above a mile from the centre of the village, was ſerved for many years by the late Rev. Jonathan Boucher, who died here in the year 1804. A large old ſeat near the church, called *Durdans*, was originally built by George, the firſt earl of Berkley, with the materials brought from the palace of Nonſuch, when that celebrated royal manſion was taken down. The firſt houſe being deſtroyed by fire, another was erected, and ſubſequently poſſeſſed by the earl of Guildford. Several other ſpacious ſeats, and pleaſant villas, are found in the vicinity of Epſom, among which are Woodcote Park, the late lord Baltimore's; and Pit's-place, which receives its name from being ſituated within the excavation of a chalk pit. It is a ſingular and curious place.

Epsom, a poſt town of America, in Rockingham County, New Hampſhire, E. of Pembroke, adjoining, 10 miles E. of Concord, and 45 N. W. of Portſmouth. It was incorporated in 1727, and in 1800 contained 1034 inhabitants.

Epsom *Salt and Water*. This ſo much celebrated ſalt was firſt extracted from the purgative mineral ſpring at Epſom in Surrey, which had long been celebrated for its medicinal qualities, by Dr. Nehemiah Grew in 1675, who publiſhed a treatiſe concerning it (De Natura Salis Cathartici Amari.) Dr. Grew gave it the appropriate name of ſal catharticus amarus, or bitter purging ſalt; which is ſtill retained, together with the names of Epſom ſalt, magneſia vitriolata, or ſulphat of magneſia of modern chemical nomenclature; which ſee for the chemical properties of this ſalt.

The original Epſom ſalt, or that which was procured by the evaporation of the Epſom water, was ſold in London at a very high price. Afterwards it was prepared, very extenſively, by chemiſts of the name of Moult, about the year 1700, by evaporating the water of ſome ſprings at the foot of Shooter's-hill; which were found to reſemble that at Epſom. Soon after it was diſcovered, as appears by Haukwitz, a celebrated trading chemiſt in London, that the ſame ſalt could be procured from the bittern of ſea-water; and in a few years the ſecret tranſpired, and the ſame was prepared from ſea-water at Portſmouth, Lymington, and at Newcaſtle; by which the ſalt from the Shooter's-hill ſprings was underſold, and the works were abandoned. Epſom ſalt was for a long time only prepared in this country, and the continent was ſupplied from hence; on which account it became known in Europe under the name of Epſom, or Engliſh ſalt; but Bergman afterwards diſcovered the ſame in the Sedlitz or Seydſchutz waters in Bohemia, whence the name Sedlitz ſalt was added to its other appellations.

A conſiderable confuſion prevailed for a long time between this ſalt and Glauber's Sal Mirabile (ſulphat of ſoda,) the acid of both being the ſame, and the medicinal uſes of each, and comparative doſes, not materially differing. In fact it appears, that ſometimes the true Glauber's ſalt was made ſmall grained, by ſtirring it as it began to cryſtallize; and ſometimes the true Epſom ſalt was made large grained to imitate Glauber's; and each was occaſionally paſſed off for the other as either happened to be in moſt requeſt. This kind of fraud indeed is ſtill practiſed pretty extenſively on parts of the continent where the Epſom ſalt is not eaſily procured. Some chemical difference between the two ſalts was very ſoon aſcertained. Dr. Grew gives it as characteriſtic of the Epſom ſalt, that it coagulates with an alkali; but the nature of the earth that forms this coagulum, was not fully underſtood till the reſearches of Black and Bergman proved it to be the earth magneſia.

Epſom ſalt is a highly and juſtly eſteemed purgative medicine, and is in very conſtant uſe. The taſte is ſalt and bitter, attended, however, with a peculiar flavour approaching to ſweetneſs. Notwithſtanding its nauſeous taſte, it is often found to remain on the ſtomach when rhubarb and moſt other medicines are rejected, and in general it operates ſpeedily, effectually, and without griping or debilitating. The uſual doſe for an adult is from half an ounce to an ounce; but it ſhould be pretty largely diluted in gruel, broth, or any mucilaginous liquor.

EPSTEIN, in *Geography*, a ſmall town of Germany, formerly in the Landgraviate of Heſſe Darmſtadt, but ſince the peace of Luneville, in the territory of the princes of Naſſau Dietz. It is ſituated at no great diſtance from the confluence of the Rhine and Mayn, 18 miles N.W. of Francfort on the Mayn; and is chiefly remarkable for ſome good iron mines in its neighbourhood.

EPTACTIS, in *Natural Hiſtory*, a name given by Linkius, and ſome other authors, to a ſpecies of ſtar-fiſh, of the aſtrophyte kind, whoſe rays, or branches, at their firſt going out from the body, are only ſeven in number; but which very ſoon ſpread into more. See Star-*fiſh*.

EPTAMERIDES, in *Muſic*, a name given by M. Sauveur to one of the intervals of his ſyſtem, inſerted in the Mem. de l'Acad. des. Sc. for 1701.

This author begins by dividing the octave into 43 parts or merides, then each of theſe into 7 eptamerides, ſo that the octave entire comprehends 301 eptamerides, which he ſtill ſubdivides. (See Decameride.) The word is formed of ιπτα, *ſeven*, and of μερις, *a part*. In Sauveur's ſubdiviſion the octave is $= 23\frac{10}{301}\Sigma + \frac{21}{301}f + \frac{53}{301}m$: and its common logarithm is = .9989999.0035. or .9990000.0000 according to the aſſumption of M. Sauveur, wherein the octave = .6990000.0000 and its reciprocal .3010, &c.

EPTE, in *Geography*, a ſmall river of France in the department of the Eure, which has its ſource near Bernay, and falls into the Seine below Vernon.

EPULÆ. See ENTERTAINMENTS.

EPULARES, in *Antiquity*, an epithet given to thoſe who were admitted to the ſacred epulæ or entertainments; it being unlawful for any to be preſent at them who were not pure and chaſte.

EPULIS, (from επι, *upon*, and ουλα, *the gums*,) in *Surgery*, a tubercle on the gums. There are two kinds; one of a benign nature, and free from pain; the other more malignant, being very troubleſome, and occaſionally becoming, according to the deſcriptions of ſurgical writers, of a cancerous quality. Some of the excreſcences are repreſented as having a narrow pedicle, while others are connected with the gum by means of a broad baſe.

The beſt plan of treatment conſiſts in extirpating an epulis, as ſoon as the nature of the caſe manifeſts itſelf. The object may be accompliſhed either with cauſtic, or the knife. The latter mode is that, to which we ſhould generally give the preference, becauſe attended with the greateſt degree of certainty, and not more pain.

Some writers adviſe us to tie the excreſcence, when its neck is narrow. However, in ſuch a caſe, the knife, or a pair of ſciſſars, might alſo be very conveniently employed.

EPULO, in *Antiquity*, the name of a miniſter of ſacrifice among the Romans.

The pontifices, not being able to attend all the ſacrifices performed at Rome, to ſo many gods as were adored by that people, appointed three miniſters, whom they called epulones, becauſe they conferred on them the care and management of the epulæ, feaſts in the ſolemn games and feſtivals.

To them belonged the ordering and ſerving the ſacred banquet offered on ſuch occaſions to Jupiter, &c. They wore a gown bordered with purple, like the pontifices, their number was at length augmented from three to ſeven, and afterwards by Cæſar to ten.

Their firſt eſtabliſhment was in the year of Rome 558, under the conſulate of L. Furius Purpureo, and M. Claudius Marcellus.

EPULOTICS, (from επουλυω *to cicatrize*), in *Surgery*, topical applications, which diſpoſe wounds and ulcers to heal.

EPULUM, in *Antiquity*, *banquet*, a holy feaſt prepared for the gods.

The ſtatues of the gods were commonly laid upon a bed, and ſerved in the epula, as if they had been very hungry; to perform which was the function of the miniſters of ſacrifice, hence called epulones.

EPWORTH, in *Geography*, a market town in Lindſey diviſion of Lincolnſhire, England, is ſituated 158 miles from London: it is built in a ſtraggling irregular manner; and contains, according to the late population return, 275 houſes, and 1434 inhabitants, who are chiefly employed in ſpinning hemp and flax, of which great quantities are grown here, and in the manufacture of ſacking and bagging, which is the chief trade of the town. A weekly market is held on Thurſdays, and two fairs annually. Quantities of large oaks, firs and other trees, ſome of which appear to have been burnt, and others cut down, are frequently found here three feet beneath the ſurface of the earth. The rectory of Epworth was held by the Rev. Samuel Weſley, the father of the diſtinguiſhed leaders of the Arminian Methodiſts, John and Charles Weſley.

EQUABLE MOTION, is that whereby the moveable body proceeds with the ſame continued velocity; neither accelerated nor retarded.

EQUABLE *Pulſe*. See PULSE.

EQUABLE *Style*. See STYLE.

EQUABONA, in *Ancient Geography*, a town of Spain, in Luſitania, according to the Itinerary of Antonine, ſituated on the left ſide, and at the mouth of the Tagus, not far from the ſea.

EQUAL, a term of relation between two or more things of the ſame magnitude, quantity, or quality.

Wolfius defines equals to be thoſe things which may be ſubſtituted for each other, without any alteration of their quantity. It is an axiom in geometry, that two things which are equal to the ſame third, are alſo equal to each other. And again, if to or from equals you add or ſubtract equals, the ſum or remainder will be equal.

EQUAL *Altitudes*, in *Practical Aſtronomy*. One of the moſt practicable and certain methods of determining the time, and thus aſcertaining the error of a clock or chronometer, is by obſerving equal altitudes of the ſun, or of a fixed ſtar. For this purpoſe all that is neceſſary is to obſerve the inſtant the ſun or ſtar is at any altitude towards the eaſt, before the meridian paſſage; and the inſtant muſt likewiſe be marked when the ſame object attains exactly the ſame altitude towards the weſt, after the meridian paſſage: the mean between the above quantities will be the inſtant marked by the clock at the moment the ſun or ſtar was on the meridian. The preceding operation, however, ſuppoſes, that the declination of the object has not varied during the elapſed interval, but this with the ſun ſeldom happens. The obſervation, therefore, muſt be corrected by a table, or by a direct calculation.

Let P (*Plate* XII. *Aſtronomy*, *fig*. 106.) be the elevated pole, Z the zenith, S the ſun, S B an arc parallel to the horizon H O, ſo that the points B and S have the ſame altitude; P S the polar diſtance of the ſun in the morning, P B its polar diſtance in the evening (ſuppoſed to have become leſs). When the ſun in the afternoon arrives at the point B, whoſe altitude ſuppoſe 20°, the ſame as the morning, the hour angle Z P B, or the diſtance of the ſun, and its hour angle from the meridian P Z, will be greater than the morning hour angle Z P S. We have, therefore, two triangles, Z P S, Z P B, which have each the ſide P Z common, and the ſides Z S, Z B, each equal to 70°, ſince they are the complements of the altitudes, 20° in each caſe. The ſides P S, P B, differ by a quantity which is equal to the change of the ſun's declination in the interval between the two obſervations. If the two triangles be reſolved ſeparately, the two hour angles will be found different: the half of this difference is the correction, which muſt be applied to the middle point of time to obtain the exact inſtant of the ſun's paſſage over the meridian. This correction is given in the annexed table, which is taken from the laſt edition of La Lande's Aſtronomy. It is calculated from the following differential analogy.

$$\frac{\partial x}{30}\left(\frac{\text{tang. latitude}}{\text{ſin. hour-angle}} \pm \frac{\text{tang. dec. } \odot}{\text{tang. hour-angle}}\right)$$

TABLE

☞ Multiply the Tangent by the Latitude, and if it is South, change the Signs.

Equal-*Altitude Inſtrument*, is an inſtrument uſed in *Aſtronomy* for aſcertaining the exact time at any place, by means of equal altitudes of any heavenly body, as obſerved ſucceſſively at the oppoſite ſides of the meridian. Formerly, the inſtrument uſed excluſively for this purpoſe was a refracting teleſcope of conſiderable length, attached to a vertical axis of motion, placed truly perpendicular to the horizon by means of a plumb-line or ſpirit-level, ſo that when the teleſcope had a given elevation, it might be fixed at that elevation, and deſcribe a parallel of altitude as the vertical axis turned round; which method was equally ſimple and accurate, as it required no graduated circles for reading either horizontal or vertical angles; but then its utility was limited to the ſingle operation of determining the inſtant when any celeſtial body on the weſtern ſide of the meridian had the ſame altitude that it had at a given inſtant on the eaſtern ſide, and hence the intermediate inſtant when the ſaid body was on the meridian, provided its declination had not ſenſibly altered during the interval. But in the preſent improved ſtate of aſtronomical and nautical inſtruments, almoſt any of them will meaſure equal altitudes with great preciſion, and at the ſame time indicate the quantity of the altitudes obſerved, ſo that an inſtrument to take equal altitudes only is no longer a deſideratum, and its origin and conſtruction may now be conſidered as matter of curioſity, or as a link in the hiſtorical chain of aſtronomical inſtruments, but yet at the time was a link of great importance. When ſir Iſaac Newton preſented to the obſervatory at Trinity college, Cambridge, an excellent pendulum clock for the uſe of the profeſſor, it became a matter of great importance to have the ready means of adjuſting the rate of the clock to exact time; profeſſor Cotes, therefore, contrived an equal-altitude inſtrument, which was made at very little expence, and which yet fully anſwered its purpoſe. This inſtrument is deſcribed in Dr. Robert Smith's Optics, and alſo another, which is an improvement on it, as being at that time in the poſſeſſion of the earl of Ilay. As we preſume it will not be unacceptable to our readers to ſee how an inſtrument, that does not indicate any meaſure, will yet determine equal altitudes with accuracy, we ſhall give in ſucceſſion brief deſcriptions of the two inſtruments we have already named, accompanied by correſponding figures.

Profeſſor Cotes' Equal-altitude Inſtrument.—*Fig.* 3. of *Plate* XVII. of *Aſtronomical Inſtruments*, is a repreſentation of Mr. Cotes' equal-altitude inſtrument, as applied in taking an obſervation. A B is a ſtrong wooden axis in a vertical poſition about ſix feet long, and having the extreme ends of well-tempered ſteel; the ſuperior end A has a cylindrical pivot, and the lower end a conical one, both reſting in adjuſtable pieces of metal, that are not neceſſary to be deſcribed; two ſtrong bars, C D and D E, are firmly attached to the axis, ſo as to form a right angle where they are united at D; in like manner two other bars are fixed together and to the axis, namely, G F and F E, making a right angle at F; and below theſe a thick pin Y paſſes quite through the axis. Near the top at T is a piece of tapped wire ſcrewing into the axis, and ſupporting a plumb-line T V, which falls at the point of a fine needle inſerted a little out of the centre of the thick pin Y; ſo that by turning this wooden pin round, the needle point may be brought into contact with the line whenever it does not touch it: the bar C D has half a dozen tapering pins or pegs turned round, inſerted into holes at equal diſtances, or nearly ſo, and the bar E F has one ſuch pin. The pin at F ſupports the lower end of the teleſcope P Q, and the upper or object end hangs by one of the ſix pins on the arm C D, as the elevation in any obſervation may require; the piece I L K M, that carries the peg N, by which the teleſcope hangs, being made faſt to its tube. The teleſcope, not being an achromatic at that time, was five feet long, and therefore required the axis of motion to be at leaſt ſix feet. When the pivots of the axis were nicely adjuſted with reſpect to eaſt and weſt, and alſo to north and ſouth, which was known by the plumb-line hanging in apparent contact with the needle point, during the whole of an entire revolution, then the object-end of the teleſcope deſcribed an exact parallel to the horizon, or parallel of altitude, and whatever bodies appeared in the centre of the eye-glaſs, which we ſuppoſe to have been a ſingle one, had all equal apparent altitudes.

The Earl of Ilay's Equal-altitude Inſtrument.—The inſtrument ſaid to have been in the poſſeſſion of the earl of Ilay, is repreſented by *fig.* 4. of *Plate* XVII. We know not who was the maker, otherwiſe we ſhould have given his name in preference. The axis *a b* is of ſteel ſquared, thirty inches long; the upper end of it, *a*, bears a ſextantal arch *c d*, fixed at *a* immoveably; the teleſcope N is thirty inches long alſo, and is moveable together with its graduated ſemi-circle round the ſame point *a* as a centre of motion: this ſemi-circle may be fixed to the ſextantal arch at any elevation of the teleſcope, by the finger-nuts *c* and *d*, paſſing through the circular aperture of the ſemi-circle, and ſcrewing into the ſextantal arch. Immediately under the ſemi-circle is a ſpirit-level *l m*, with ſcrews of adjuſtment, and at *e* under it, the axis, for a ſhort way down, is cylindrical, about an inch in diameter, and well-poliſhed. The lower end of the axis is conical, and the eye-piece of the teleſcope has in its focus five vertical wires at equal diſtances, parallel to each other, and two parallel croſs wires, as repreſented in *fig.* 5. When the inſtrument here deſcribed is uſed, its axis is let down into a ſtand of the ſhape of a long hollow parallelopiped, wanting two ſides. Its other ſides *f*, *g*, are a couple of braſs plates, equal in length to the part *b e* of the axis, and are ſcrewed together edgeways, but the centre of the upper ſquare end piece *h*, four inches ſquare, is a round hole, juſt large enough to receive without touching it, and over this hole is fixed another plate with a triangular hole, concentric, one of the ſides of which triangle is moveable by an adjuſtment ſcrew, to make the cylinder bear alike on all ſides: on the lower ſquare, or baſe *i*, lies another adjuſtable piece, with a fine conical hole to bear the point *b* of the axis, and to adjuſt the axis vertical by means of its ſcrews, as pointed out by the level. The frame, thus furniſhed with the inſtrument, is then firmly faſtened to a ſolid pillar K, by means of a niche made in it to receive the braſs plates. The axis is known to be truly perpendicular when the bubble of the level will remain in the middle of the tube during every part of an entire revolution of the axis. If the axis of this inſtrument were to be placed parallel to the earth's axis, and in the true meridian, its conſtruction is equally adapted for an equatorial teleſcope, in which caſe the ſemi-circle would in every ſituation be a ſecondary to the equator, or would meaſure declinations. The croſs wires in the teleſcope are very uſeful for taking five pairs of obſervations, from which a mean may be taken with greater accuracy than one pair of obſervations alone would give, and in cloudy weather will afford five chances of ſeeing the body at the proper inſtants of required altitude. For the methods of applying the corrections for equal altitudes, and of aſcertaining the exact time as deduced from the obſervations, the reader is requeſted to conſult our article CHRONOMETER, where the requiſite problems are exemplified. It is ſcarcely neceſſary to add, that a common Hadley's ſextant or octant is a good inſtrument for taking equal altitudes, provided the obſerver have a good artificial horizon, when his obſervations are taken on the land; the imperfection of the graduations being of no importance, except when the exact meaſure is wanted for other purpoſes.

Equal *Angles*, are thoſe whoſe containing lines are inclined alike to each other; or which are meaſured by ſimilar arches of their circles.

Equal *Arches*. See Arch.

Equal *Arithmetical Ratios*, are thoſe wherein the difference of the two leſs terms is equal to the difference of the two greater. See Ratio.

Equal *Circles*, are thoſe whoſe diameters are equal. See Circle.

Equal *Curvatures*, are ſuch as have the ſame or equal radii of curvature. See Curvature.

Equal *Figures*, are thoſe whoſe areas are equal, whether the figures be ſimilar or not.

The ſegments of a ſphere, or circle, are of an equal concavity, or convexity, when they have the ſame ratio, or proportion to the diameters of the ſpheres, or circles, whereof they are parts.

Equal *Geometrical Ratios*, are thoſe whoſe leaſt terms are ſimilar, aliquot, or aliquant parts of the greater.

Equal *Hours*. See Hour.

Equal *Hyperbolas*, are thoſe, all whoſe ordinates to their indeterminate axes, are equal to each other; taken at equal diſtances from their vertices.

Equal *Solids*, are thoſe which comprehend, or contain, each as much as the other; or whoſe ſolidities, or capacities, are equal. See Solid.

Equal *Beating*, in *Muſic*, is ſaid of ſuch tempered concords as beat equally quick, or make the ſame number of *wa, wa, wa, wa's*, in a given ſpace of time, when ſounding. The firſt who mentions, or makes any uſe of equal-beating concords, is Dr. Robert Smith, who obſerves, (Harmonics, p. 188.) "if ſeveral imperfect conſonances of the ſame name, as Vths, for inſtance, (by which the whole ſcale is uſually tuned,) beat equally quick, they are not equally harmonious, or tempered; to make them ſo, the higher in the ſcale ought to beat as much quicker than the lower, as their baſes vibrate quicker (prop. xi. cor. 2.); that is, if a Vth be a minor tone higher than another, it ſhould beat quicker, in the ratio of 10 to 9, or (if a major tone) 9 to 8 nearly; if a IIId higher, in the ratio of 5 to 4; if a Vth higher, in the ratio of 3 to 2; if an VIIIth higher, of 2 to 1, &c.

In ſchol. 2. to prop. xx., the doctor gives a table of beats to be made in fifteen ſeconds of time, by four ſucceſſive 5ths above C reſpectively, in order to form a ſyſtem for the common inſtruments with twelve notes in an octave, wherein every IIId ſhall beat ſharp, as faſt as the Vth to the ſame baſe beats flat: let it be obſerved, however, that this will not be the caſe in the IIIds or Vths affected by the beating notes, or reſulting 5th, after this method has been purſued through eleven 5ths.

In the ſame table we have the number of beats for the above ſucceſſion of 5ths, ſo calculated, that the Vths and VIths to the ſame baſs may beat equally quick, the former flat, and the latter ſharp; which will give the notes of the doctor's ſyſtem of equal harmony in three octaves, as far as the ſame can be applied on a defective or douzeave inſtrument. At page 220, mention is made of another equal-beating ſyſtem, wherein the IIIds and the VIths to the ſame baſs beat equally quick, and which is ſaid to approach ſo near to the ſyſtem of equal harmony, as not to need a particular table.

In the directions given by earl Stanhope, pages 13 and 14, of his ſtereotype "Principles of the Science of Tuning," for adjuſting his two ſucceſſive biequal 3ds, and three ſucceſſive triequal quints; his lordſhip directs that theſe ſhall be made to beat equally quick reſpectively; and falls into the miſtake of ſuppoſing that this would produce the equal temperament of thoſe IIIds and the Vths reſpectively, that he had previouſly calculated for them, by mean proportionals, for his monochord ſyſtem, contrary to the demonſtrations of Dr. Smith above; and in a printed "Letter to the Duke of Cumberland reſpecting the Stanhope Temperament," this error being perſiſted in, after it had been pointed out by Mr. Farey in the Philoſophical Magazine, vol. xxvii. p. 203, it becomes neceſſary for us to point out (as could not be done under Biequal *Third*, in our work), that the ratios $\frac{4}{5}$, $\frac{12}{19}$, and $\frac{1}{2}$, exactly repreſent the notes E, ♭ A and *c* reſpectively, when the two ſucceſſive 3ds (which his lordſhip calls biequal) E, ♭ A and ♭ A *c*, whoſe ratios are $\frac{15}{19}$ and $\frac{19}{24}$, make an equal number of beats in a ſecond of time; and this number of beats, when C makes 240 complete vibrations in 1″, is exactly ten times in a ſecond. Thus we ſee, that there are three different intervals, called by his lordſhip biequal thirds, whoſe ratios are $\frac{19}{24}$, $\frac{\sqrt{10}}{4}$, and $\frac{15}{19}$, and their common logarithms are .8985423.5924, .8979400.0867, and .8973376.5811 reſpectively, or in the new notation $206.228\,\Sigma + 4f + 18\,m$, $207.5\,\Sigma + 4f + 18\,m$, and $208.772\,\Sigma + 4f + 18\,m$ nearly reſpectively: and there are, indeed, others which ariſe from the new inſtructions which his lordſhip gives in the letter to the duke of Cumberland above referred to, for tuning equally-tempered concords by means of the *abſence* of "beating between the two beatings;" which new ſpecies of equal beating is conſidered in the Philoſophical Magazine, vol. xxxiii. p. 297, and is ſhewn to produce other intervals than the above, and which yet come under the appellation of biequal thirds, as defined by earl Stanhope.

Equal *Harmony*, has been applied by Dr. Robert Smith to the different concords V, VI, and III, (or their complements 4th, 3d, and 6th,) when they are ſo tempered, as to be equally harmonious or pleaſant to the ear, as tempered concords; and the reſult of his laborious calculations for forming a ſyſtem, wherein every concord within the compaſs of *three* octaves ſhall be equally and the moſt harmonious, (Harmonics, p. 140.) is, that each V, VI, and III, are to be tempered $\frac{-5}{18}$, $\frac{+3}{18}$, and $\frac{-2}{18}$ parts of a major comma reſpectively: or, in a ſyſtem of four octaves of equally harmonious concords, theſe temperaments are to be $\frac{-11}{40}$, $\frac{+7}{40}$, and $\frac{-4}{40}$ parts of a comma for the V, VI, and III, reſpectively. But it is to be obſerved, that theſe temperaments are applicable only to inſtruments with 21 ſtrings, or pipes, in each octave, and not to the common piano-fortes, organs, &c. in uſe, with only 12 ſtrings, or pipes, of different pitches within the compaſs of an octave.

The term equal harmony has been, as we think, improperly applied by Mr. Emerſon, and others, to the *iſotonic* or *equal temperament* ſyſtem of intervals (which ſee); it being obſervable that Dr. Smith's deſign is to effect an equal harmony among the different concords, and the equal temperament makes an equal harmony among the different keys, which are in effect very different ſyſtems, and ought not to bear the ſame name.

Equal harmony alſo denotes the tuning by perfect 5ths without temperament, making all the keys participate equally of the imperfection of the ſcale on keyed inſtruments. By this method of tuning, the thirds will, at firſt, ſeem very harſh and crude; but by a little uſe the ear will accommodate itſelf to the evil, and indulge the abbé Rouſſier, or his manes, with the *triple progreſſion*, by which Pythagoras formed the ſcale, and by which the Chineſe, in the moſt remote antiquity, according to Pere Amiot, produced the few ſounds with which their imperfect ſcale is furniſhed. See Temperament and Triple *Progreſſion*.

Equal *Temperament*, is a ſyſtem of twelve intervals within an octave, all equal to each other; each of which has the ratio of $\sqrt[12]{2} = 51\Sigma + f + 4\frac{5}{12}m$, (ſee Philoſophical Magazine, vol. xxix. p. 347.) the common logarithm of each of ſuch mean ſemitones being = .9749141.6703. This ſyſtem is often called the iſotonic, and ſometimes that of Merſennus, by M. Couperin, M. Marpurg, Mr. Emerſon, Mr. Cavallo, Mr. Davis, and others, who have written in its favour. Dr. Robert Smith, who diſapproves of this ſyſtem, ſtates the temperaments of its V and 4th, its VI and 3d, and its III and 6th, to be $\frac{1}{10}$, $\frac{7}{10}$, and $\frac{6}{10}$ parts of a major comma reſpectively (Harmonics, p. 167.), but theſe are incorrect, and ought to have been $\frac{1}{11}$, $\frac{7}{11}$, and $\frac{6}{11}$ of a comma, the temperaments of theſe concords, very nearly, as ſtated in the firſt column of Tab. II. page 158, of the ſame work. Mr. Emerſon, in his "Algebra," prob. ccii. calculates the beats which the concords in this ſyſtem make, in the octave above the G of the baſs cliff, and ſtates theſe at − 15, + 11, + $1\frac{1}{2}$, − 1, − 18, and + 13 in one ſecond of time, made by the 3d, III, 4th, V, 6th, and VI reſpectively, the flat temperaments being marked − and the ſharp ones +.

The equal temperament of Mr. Farey, (Philoſophical Magazine, vol. xxviii. p. 65, and xxx. p. 6.) differs only in an inſenſible degree from the above, his half note being $51\Sigma + f + 5m$ between the notes C and ♭D, ♭E and E, F and ♭G, G and ♭A, and ♭B and B; and $51\Sigma + f + 4m$ between the notes ♭D and D, D and ♭E, E and F, ♭G and G, ♭A and A, A and ♭B, and B, &c.; yet this very ſlight variation enables an organ tuner to tune the twelve notes of this ſyſtem, by help of certain combinations of perfect Vths, 4ths, and IIIds! In this method of obtaining an equal temperament, the ſucceſſive 5ths C G, G D, D A, A E, E B, B ♭G, G ♭D, and D ♭A, are to be tuned upwards, each by aſcending (on a ſpare range of pipes or different ſtop to the one intended to be tuned) five ſucceſſive perfect 4ths, and from the higheſt note of theſe deſcending two perfect 5ths and one major 3d, which laſt or loweſt note is to be transferred to the G of the ſtop intended to be tuned. From this ſame note, G, five 4ths up, and two V + III down, are to be tuned to get D, and ſo on to ♭A. The remaining 5ths *c* F, F ♭B, and ♭B ♭E, are to be tuned downwards, by deſcending from *c* five ſucceſſive 4ths, and thence aſcending two Vths and a IIId to obtain F, from which note, repeating the ſame proceſs until the note ♭E is obtained; when, if the operations have been carefully performed, and *no beats* ſuffered to remain in any of the perfect 4ths, 5ths, 3ds, or uniſons, or in the octave C *c*, &c. the reſulting 5th, or that between the beating notes ♭A and ♭E, will be found, but in an almoſt inſenſible degree flatter than all the other fifths in the ſcale; the difference being only *m*, or leſs than $\frac{1}{1400}$th part of a major comma! between this V and each of the other eleven Vths: this being $357\Sigma + 7f + 30m$, and each of the others $375\Sigma + 7f + 31m$. The logarithm of the firſt or largeſt of the half-notes in this ſyſtem is = .9749119.1920, and of the ſmalleſt .9749157.7262. See Temperament.

Equal, in *Optics*. We ſay, that things ſeen under equal angles are equal. Equal parts of the ſame interval, or magnitude, if unequally diſtant from the eye, appear unequal. Equal objects, and at equal diſtances, only the one placed directly, and the other obliquely, ſeem unequal; and that placed directly, the bigger.

Maſonry by Equal *Courſes*. See Masonry.

EQUALITY, in *Algebra*, is a compariſon of two quantities, that are equal both really and repreſentatively, *i.e.* which are ſo both in effect and letters.

A compariſon of two quantities equal in effect, but unequal in letters, to render them equal, is called an *equation*, which ſee.

Equality is uſually denoted by two parallel lines, as =: thus $2 + 2 = 4$, *i.e.* 2 plus 2 are equal to 4. This character was firſt introduced by Robert Recorde. Des Cartes, and ſome after him, in lieu thereof, uſe $\propto$: thus, $2 + 2 \propto 4$; ſo $z - y \propto b + c$; ſignifies that *z* minus y is equal to b plus c.

From an equation we arrive at an equality, by changing an unknown letter into another, whereby the two members of the equation, *i.e.* the two quantities compared together, and connected by the ſign of equality, are rendered equal. Thus, in the equation $aax = bcd$; ſuppoſing $x = \frac{bcd}{aa}$, we change *x* into $\frac{bcd}{aa}$, and by this ſubſtitution arrive at the equality $bcd = bcd$.

In the ſolution of a numerical problem, which is to be rendered rational, if there be only one power to be equalled to a ſquare, or other higher power, it is called ſimple equality.

Where there are two powers to be equalled, each to a ſquare, it is called double equality, &c.

Diophantus hath given us a method for double equalities, and F. de Billy, another for triple equalities, in his Diophantus Redivivus.

EQUALITY, in *Aſtronomy*. *Circle of* Equality, or the *equant*. See Circle and Equant.

Equality denotes the exact agreement of two or more things in reſpect of quantity. Thus, figures are equal which may occupy the ſame ſpace, by the fluxion or tranſpoſition of their parts. See on this ſubject an elaborate diſſertation by Dr. Barrow, in the 11th and 12th of his Mathematical Lectures.

Equality, *ratio*, or *proportion of*, in *Geometry*, is that between two equal numbers, or quantities.

Proportion of Equality *evenly ranged*, or *ex æquo ordinata*, is that in which two terms in a rank, or ſeries, are proportional to as many terms in another ſeries, compared to each other in the ſame order, *i.e.* the firſt of one rank to the firſt of another; the ſecond to the ſecond, &c.

Proportion of Equality *evenly diſturbed*, called alſo *ex æquo perturbata*, is that in which more than two terms of one rank are proportional to as many terms of another compared to each other, in a different and interrupted order; *viz.* the firſt of one rank to the ſecond of another; the ſecond to the third, &c.

Equality, *Union of*. See Union.

Equality, in *Law*, the law delights in equality; ſo that when a charge is laid upon one, and divers ought to bear it, he ſhall have relief againſt the reſt. 2 Rep. 25.

EQUANIMITY, in *Ethics*, denotes an even, uniform temper of mind, amidſt all the varieties and revolutions of time and chance. This virtue, together with prudence, forms the character which Horace gives of Ariſtippus:

"Omnis Ariſtippum decuit color & ſtatus & res."

EQUANT, or ÆQUANT, in *Aſtronomy*, a circle, formerly imagined by aſtronomers, in the plane of the deferent, or eccentric; for regulating and adjuſting certain motions of the planets, and reducing them more eaſily to a calculus. See APOGEE, CIRCLE, DEFERENT, and EXCENTRIC.

EQUATED ANOMALY. See ANOMALY and ELLIPTIC *Motion*.

EQUATED *Bodies*. On Gunter's ſector there are ſometimes placed two lines, anſwering to one another, and called the lines of equated bodies: they lie between the lines of ſolids, and ſuperficies, and are noted with the letters D, I, C, S, O, T, for dodecahedron, icoſihedron, cube, ſphere, octahedron, and tetrahedron.

The uſes of theſe lines are, 1. When the diameter of the ſphere is given, to find the ſides of the five regular bodies, ſeverally equal to that ſphere. 2. From the ſide of any of the bodies being given, to find the diameter of the ſphere, and the ſides of the other bodies, which ſhall be equal ſeverally to the firſt body given.

If the ſphere be firſt given, take its diameter, and apply it over in the ſector in the points S, S: if any of the bodies be firſt given, apply the ſide of it over in its proper points; ſo the parallels taken from between the points of the other bodies ſhall be the ſides of thoſe bodies, equal ſeverally to the firſt body given.

EQUATION, in *Algebra*, is when two equal quantities, differently expreſſed, are compared together, by means of the ſign = placed between them.

Thus, $9 - 4 = 5$, is an equation expreſſing the equality of $9 - 4$ and 5; and $a + b - c = d$, is an equation denoting that the difference between the ſum of $a + b$, and c, is equal to d; the quantities between which the ſign = is placed being called the two ſides of the equation.

It is ſometimes cuſtomary, however, to place all the quantities on one ſide of the equation, and to make them equal to 0, or zero, on the other ſide; as $a - b = c$, or $a + b - c = 0$, &c. which is only ſetting down the difference of two equal quantities and putting it equal to 0.

The *terms* of an equation, are the ſeveral quantities or parts of which it is compoſed: thus, in the equation $a + b = c$, the terms are a, b, and c; and the ſenſe or meaning of the expreſſion is, that ſome quantity repreſented by c, is equal to the ſum of two others, repreſented by a and b.

When a quantity ſtands alone, on one ſide of an equation, the terms on the other ſide are ſaid to be a *value* of that quantity. Thus, in the equation $x = a - b$, the difference of the two numbers repreſented by a and b is called the value of x.

Equations are alſo diſtinguiſhed by the denominations of *ſimple* and *compound*, or, as they are frequently called, *ſimple* and *affected*; which latter term, however, it would be better to diſcard, as being leſs natural and appropriate than that of *compound*.

A ſimple equation, is that which contains only one power of the unknown quantity; as $x + a = b$, or $a x^2 + b = c$, or $2 x^3 + 3 a^3 = 4 b$, &c. where x denotes the unknown quantity, and the other letters or figures ſuch quantities as are known.

A compound equation, is that which contains two or more powers of the unknown quantity; as $x^2 + a x = b$, or $x^3 + a x^2 - b x = c$, &c.

Equations are likewiſe divided into different *orders*, according to the higheſt power of the unknown quantity contained in any one of their terms; as *quadratic*, *cubic*, *biquadratic*, &c. thus,

A quadratic equation, is that in which the unknown quantity riſes to two dimenſions, or that contains both the unknown quantity and its ſquare; as $x^2 + 10 x = 30$, or $a x^2 + b x = c$.

A cubic equation, is that in which the unknown quantity is of three dimenſions, or that riſes to the cube or third power; as $x^3 - 3 x = 1$, or $x^3 + 2 x^2 = 4$, or $a x^3 + b x^2 + c x = d$.

A biquadratic equation, is that in which the unknown quantity is of 4 dimenſions, or that riſes to the fourth power; as $x^4 + 2 x = 5$, or $x^4 + 3 x^2 = 10$, or $x^4 + 4 x^3 + 7 x = 50$, or $a x^4 + b x^3 + c x^2 + d x = e$. And ſo on, for the 5th, 6th and other higher order of equations; which are all denominated according to the higheſt power of the unknown quantity contained in any one of their terms.

The root of an equation, is that quantity, whether poſitive, negative, or even imaginary, that when ſubſtituted for the unknown quantity, will make both ſides of the equation vaniſh, or become equal to 0.

Thus, in the equation $x^2 - 6 x = 72$, either $+ 12$ or $- 6$ is a root, or value, of the unknown *quantity*; for if each of theſe numbers be ſeparately ſubſtituted for x, they will be found to ſatisfy the conditions of the equation.

In the reſolution of an equation, containing only one unknown quantity, ſeveral previous operations are often required to be performed, in order to adapt it to the rule to which it belongs; the greater part of which may be performed by means of a few ſelf-evident and obvious principles; namely, that if equal quantities be added to, or ſubtracted from, equal quantities, the ſums or remainders will be equal; if equal quantities be multiplied or divided by the ſame quantity the products or quotients will be equal; or if equal quantities be raiſed to the ſame power, or have the ſame root extracted, the reſults will ſtill be equal.

From theſe ſimple conſiderations are derived the following rules, which will equally apply to equations of all orders, and are alone ſufficient for the reſolution of ſimple equations.

Rule 1.—Any quantity may be tranſpoſed from one ſide of the equation to the other by changing its ſign.

Thus, if $x - 5 = 8$
Then $x = 8 + 5$
Or $x = 13$
And if $4 x - 8 = 3 x + 7$
Then $4 x - 3 x = 7 + 8$
Or $x = 15$

From this rule it alſo follows that if any quantity be found on each ſide of the equation, with the ſame ſign, it may be left out of both. And that the ſigns of all the terms of an equation may be changed into the contrary ones, without affecting the truth of the equation.

Thus, if $x + 2 = 7 + 2$
Then $x = 7$
And if $a - x = b - c$
Then $x - a = c - b$
Or $x = a + c - b$

Rule 2.—If the unknown quantity, in an equation, be multiplied by any quantity, that quantity may be taken away, by dividing all the reſt of the terms by it.

Thus, if $7 x = 49$
Then $x = \frac{49}{7} = 7$
And if $a x = b - c$
Then $x = \frac{b - c}{a}$

Rule 3.—If any term of an equation be a fraction, its denominator may be taken away, by multiplying all the reſt of the terms by it.

Thus, if $\frac{x}{2}=3$
Then $x=6$
And if $\frac{x}{a}-b=c$
Then $x-ab=ac$
Or $x=a(b+c)$

Or the denominators may be taken away from ſeveral terms of an equation, by one operation, if all the terms be multiplied by any number which is a multiple of each of the denominators.

Thus, if $\frac{x}{2}+\frac{x}{3}+\frac{x}{4}=6$

Then, if all the terms be multiplied by 12, which is a multiple of 2, 3 and 4,
We ſhall have $6x+4x+3x=72$
And $13x=72$
Or $x=\frac{72}{13}=5\frac{7}{13}$

It alſo appears, from this rule, that if each of the terms of an equation be either multiplied or divided by the ſame quantity, that quantity may be left out of them all.

Thus, if $ax=ab+ac$
Then $x=b+c$
And if $\frac{x}{a}+\frac{b}{a}=\frac{c}{a}$
Then $x+b=c$
Or $x=c-b$

4. If the unknown quantity, in any equation, be in the form of a ſurd, let it be made to ſtand alone on one ſide of the equation, and the remaining terms on the other; then involve each ſide to a power denoted by the index of the ſurd, and the quantity will thus be rendered free from any ſurd expreſſion.

If, for example, $\sqrt{x}+2=5$
Then, by tranſpoſition, $\sqrt{x}=5-2=3$
And, by ſquaring both ſides, $x=9$
In like manner, if $\sqrt{x^2+a}-x=b$
Then, by tranſpoſition, $\sqrt{x^2+a}=b+x$
And by ſquaring $x^2+a=b^2+2bx+x^2$
And by leaving out x^2 on each ſide $a=b^2+2bx$
Or $a-b^2=2bx$
Or $x=\frac{a-b^2}{2b}$

5. Any analogy, or proportion, may be converted into an equation, by making the product of the two extremes equal to that of the two means.

Thus, if $3x:16::5:7$
Then $3x\times 7=16\times 5$
Or $21x=80$
Or $x=\frac{80}{21}=3\frac{17}{21}$

Having thus ſhewn the manner in which a ſimple equation, containing only one unknown quantity, may be ſolved, it will be proper, in the next place, to explain the methods by which two or more equations of this kind may be reduced to a ſingle one, and thence reſolved by ſome of the foregoing rules; obſerving, in this caſe, that there muſt always be the ſame number of equations as there are unknown quantities, otherwiſe the queſtion will admit of a variety of anſwers.

The principal methods, made uſe of for this purpoſe, as far as regards the reſolution of two ſimple equations, are the three following:

1. Obſerve which of the unknown quantities is the leaſt involved, and find its value in each of the two equations by the methods already explained.

This being done, let the values, thus found, be put equal to each other; and there will ariſe a new equation, with only one unknown quantity in it, the value of which may be found as before.

As an example in this caſe, let it be required to determine x and y from the two following equations.

$2x+3y=23$
$5x-2y=10$

Then, from the 1ſt equation $x=\frac{23-3y}{2}$
And from the 2d, $x=\frac{10+2y}{5}$
Hence, if theſe two values be put equal to each other,
We ſhall have $\frac{10+2y}{5}=\frac{23-3y}{2}$
Or $20+4y=115-15y$
Therefore $15y+4y=115-20$
Or $19y=95$
And conſequently $y=\frac{95}{19}=5$
And $x=\frac{10+2y}{5}=\frac{10+10}{5}=\frac{20}{5}=4$

2. Conſider which of the unknown quantities you would firſt exterminate, and find its value in that equation where it is the leaſt involved.

Then ſubſtitute this value for its equal in the other equation, and there will ariſe a new equation, with only one unknown quantity in it, the value of which may be found as before.

Thus, taking the ſame example as in the former rule.

$2x+3y=23$
$5x-2y=10$

Then, from the 1ſt equation, $x=\frac{23-3y}{2}$

And, if this value be ſubſtituted for x in the 2d equation, we ſhall have

$5\left(\frac{23-3y}{2}\right)-2y=10$
Or $115-15y-4y=20$
And conſequently $115-20=15y+4y$
Or $y=\frac{95}{19}=5$
And $x=\frac{23-3y}{2}=\frac{23-15}{2}=\frac{8}{2}=4$

3. Let the given equations be multiplied or divided by ſuch numbers or quantities as will make the term which contains one of the unknown quantities the ſame in both equations.

Then, by adding or ſubtracting the two equations, as occaſion may require, there will ariſe a new equation with only one unknown quantity in it, which may be reſolved as before.

Thus, taking the ſame example as in the two former methods.

$2x+3y=23$
$5x-2y=10$

Then, to exterminate x, let the firſt equation be multiplied by 5, and the 2d by 2, and we ſhall have

$$10x + 15y = 115$$
$$10x - 4y = 20$$

And ſubtracting the latter of theſe two equations from the former, the reſult will be

$$19y = 95$$

And conſequently $y = \frac{95}{19} = 5$

And if this be ſubſtituted for y in the laſt of the two given equations, we ſhall have

$$5x - 2 \times 5 = 10$$
$$\text{Or } 5x = 10 + 10 = 20$$
$$\text{Or } x = \frac{20}{5} = 4$$

As another example of this third method, which is commonly more eaſy and expeditious in practice than either of the other two,

Let there be given $\left\{\begin{matrix} ax + by = c \\ dx + fy = g \end{matrix}\right\}$ to find x and y

Then, in order to exterminate y, let the firſt equation be multiplied by f, and the ſecond by b, and we ſhall have

$$afx + bfy = cf$$
$$bdx + bfy = bg$$

And by taking the difference of theſe two equations, there will ariſe

$$afx - bdx = cf - bg$$
$$\text{Or } (af - bd)\,x = cf - bg$$
$$\text{And conſequently } x = \frac{cf - bg}{af - bd}$$

In like manner, if the firſt of the two given equations be multiplied by d, and the ſecond by a, we ſhall have

$$adx + bdy = cd$$
$$adx + afy = ag$$

And, the difference of theſe equations being taken as before, will give

$$bdy - afy = cd - ag$$
$$\text{Or } (bd - af) = cd - ag$$
$$\text{And conſequently } y = \frac{cd - ag}{bd - af}$$

In which caſe, x and y are here found in general terms; and conſequently the ſolution will hold true, whatever numbers may be ſubſtituted for a, b, c, d, e, f, and g.

If it be required to exterminate three unknown quantities, or to reduce the three ſimple equations containing them to a ſingle one, it may be done as follows:

Find the value of one of the three unknown quantities in each of the three ſimple equations containing it; then compare the firſt of theſe values with the ſecond, and the ſecond with the third, and there will ariſe two new equations, containing only two unknown quantities, the values of which may be found by either of the former rules.

Let there be given, for example, the three following equations, to find x, y, and z.

$$x + y + z = 53$$
$$x + 2y + 3z = 105$$
$$x + 3y + 4z = 134$$

Then, if x be exterminated in each of theſe equations, we ſhall have,

$$x = 53 - y - z$$
$$x = 105 - 2y - 3z$$
$$x = 134 - 3y - 4z$$

And by comparing the firſt of theſe with each of the other two, there will ariſe the two following equations:

$$53 - y - z = 105 - 2y - 3z$$
$$53 - y - z = 134 - 3y - 4z$$

From which, by tranſpoſition, and the rules of addition and ſubtraction, we ſhall readily find,

$$y = 52 - 2z$$
$$y = \frac{81 - 3z}{2}$$

And conſequently, by equating theſe two values of y, we ſhall obtain,

$$\frac{81 - 3z}{2} = 52 - 2z$$
$$\text{Or } 81 - 3z = 104 - 4z$$
$$\text{Or } 4z - 3z = 104 - 81 = 23$$

Hence $z = 23$

$$y = 52 - 2z = 52 - 46 = 6$$
$$x = 53 - y - z = 53 - 6 - 23 = 24$$

And if the three following equations be propoſed, in general terms,

$$ax + by + cz = d$$
$$a'x + b'y + c'z = d'$$
$$a''x + b''y + c''z = d''$$

Then the values of x, y, and z, found in a ſimilar manner, will be as below:

$$z = \frac{ab'd' - ad'b'' + da'b'' - bad'' + bd'a'' - db'a''}{ab'c'' - acb'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

$$y = \frac{ad'c'' - ac'd'' + ca'd'' - da'c'' + dc'a'' - cd'a''}{ab'c'' - ac'b'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

$$x = \frac{db'c'' - dc'b'' + cd'b'' - bd'c'' + bc'd'' - cb'd''}{ab'c'' - acb'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

Where, if any numbers whatever be ſubſtituted in the place of the literal coefficients, the equation will hold: and in a manner analogous to this, we may exterminate four or more unknown quantities in general terms; and thence, by ſubſtitution, determine their values in any numeral equations that may be propoſed.

Having thus ſufficiently ſhewn the method of ſolving ſimple equations, it will next be proper to proceed to the reſolution of quadratic equations, or thoſe of the ſecond power, which, omitting the ſimple caſe $x^2 = a$, and confining ourſelves only to ſuch as are compound, may always be reduced to one of the three following forms:

$$1.\ x^2 + ax = b$$
$$2.\ x^2 - ax = b$$
$$3.\ x^2 - ax = -b$$

Where the value of the unknown quantity x, in each of the equations, taken according to the order in which they ſtand, may be exhibited as below:

$$1.\ x = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$$

$$2.\ x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$$

$$3.\ x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}$$

Or the general equation $ax^2 \pm bx = \pm c$, which comprehends all the three caſes above-mentioned, may be reſolved by means of the following rule:

Tranſpoſe all the terms that involve the unknown quantity to one ſide of the equation, and the known quantities to the other; obſerving to arrange them ſo, that the term which contains the ſquare of the unknown quantity may be poſitive, and ſtand firſt in the equation.

Then, if the ſquare of the unknown quantity have any coefficient prefixed to it, let all the reſt of the terms be divided by it, ſo that the coefficient of the ſquare of the unknown quantity may be 1.

This being done, add the ſquare of half the coefficient of the unknown quantity itſelf to both ſides of the equation, and the ſide which involves the unknown quantity will now be a complete ſquare.

Laſtly, extract the ſquare root of both ſides of the equation, by which means it will be reduced to a ſimple one; and if the unknown quantity be made to ſtand alone, on one ſide of the equation, and the known terms on the other, its value will be determined as was required.

Note. The ſquare root of the firſt ſide of the equation is always equal to the ſum or difference of the unknown quantity, and half the coefficient of the ſecond term, according as that term is + or −.

It may alſo be obſerved, that all equations, in which there are two terms involving the unknown quantity, and which have the index of the one juſt double that of the other, are ſolved like quadratics, by completing the ſquare.

Thus, $x^4 - ax^2 = b$, or $x^{2n} - ax^n = b$, are the ſame as quadratics; their roots being as below.

$$x = \sqrt{\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}},\quad x = \sqrt[n]{\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}}$$

As an illuſtration of the rule for quadratics given above, the following ſimple examples in numbers will be found ſufficient.

1. Given $x^2 + 4x = 140$, to find x.

Here $x^2 + 4x + 4 = 140 + 4 = 144$, by completing the ſquare.

And $\sqrt{x^2 + 4x + 4} = \sqrt{144}$, by extracting the root.
Or, which is the ſame thing, $x + 2 = 12$.
And conſequently $x = 12 - 2 = 10$.

2. Given $x^2 - 6x + 8 = 80$, to find x.
Here $x^2 - 6x = 80 - 8 = 72$, by tranſpoſition.
Then $x^2 - 6x + 9 = 72 + 9 = 81$, by completing the ſquare.
And $x - 3 = \sqrt{81} = 9$, by extracting the root.
Whence $x = 9 + 3 = 12$.

3. Given $2x^2 + 8x - 20 = 70$, to find x.
Here $2x^2 + 8x = 70 + 20 = 90$, by tranſpoſition.
Then $x^2 + 4x = 45$, by dividing by 2.
And $x^2 + 4x + 4 = 45 + 4 = 49$, by completing the ſquare.
Whence $x + 2 = \sqrt{49} = 7$, by extracting the root.
And conſequently $x = 7 - 2 = 5$.

4. Given $\frac{x^2}{2} - \frac{x}{3} + 20\frac{1}{2} = 42\frac{2}{3}$.

Here $\frac{x^2}{2} - \frac{x}{3} = 42\frac{2}{3} - 20\frac{1}{2} = 22\frac{1}{6}$, by tranſpoſition.

And $x^2 - \frac{2}{3}x = 44\frac{1}{3}$, by dividing by $\frac{1}{2}$, or multiplying by 2.

Whence $x^2 - \frac{2}{3}x + \frac{1}{9} = 44\frac{1}{3} + \frac{1}{9} = 44\frac{4}{9} = \frac{400}{9}$, by completing the ſquare.

And $x - \frac{1}{3} = \sqrt{\frac{400}{9}} = \frac{20}{3}$.
Therefore $x = \frac{20}{3} + \frac{1}{3} = \frac{21}{3} = 7$.

It muſt here, however, be obſerved, that ſince the ſquare root of any quantity may be either poſitive (+) or negative (−), it follows that all quadratic equations will admit of two ſolutions. Thus, the ſquare root of a^2 (or $\sqrt{a^2}$) is either $+a$ or $-a$; for $(+a) \times (+a)$ or $(-a \times -a)$ are each equal to a^2, by the rules for the ſigns in multiplication. So, in like manner, if there be given $x^2 + ax = b$, where $x + \frac{a}{2}$ is found $= \sqrt{b + \frac{1}{4}a^2}$, the root may be $+\sqrt{b + \frac{1}{4}a^2}$, or $-\sqrt{b + \frac{1}{4}a^2}$, ſince either of them being multiplied by itſelf will produce $b + \frac{1}{4}a^2$. And this ambiguity is uſually expreſſed by writing the uncertain ſign ± before $\sqrt{b + \frac{1}{4}a^2}$, by which means we have $x = \pm\sqrt{b + \frac{1}{4}a^2} - \frac{1}{2}a$; and the ſame mode of reaſoning is equally applicable to any literal or numeral quadratic equation whatever. Thus, in the firſt numeral equation above, $x^2 + 4x = 140$, it has been found that $x + 2 = \sqrt{144} = 12$; but if the uncertain ſign ± be put before $\sqrt{144}$, it will become $x + 2 = \pm\sqrt{144} = +12$ or -12; and conſequently $x = +12 - 2 = 10$ or $-12 - 2 = -14$, which are the two roots of the equation $x^2 + 4x = 140$, as will be found by ſubſtituting either of them for x; the reſult in both caſes being 144.

In addition to this, it may be ſtill farther remarked, that a quadratic equation may be propoſed of ſuch a form, or have its coefficients ſo related to each other, that the value of the unknown quantity can only be exhibited by means of the ſquare root of a negative quantity, which, it is plain, cannot be determined; as there is no quantity, either poſitive or negative, which being multiplied by itſelf produces ſuch a form of expreſſion. If, for example, the value of x were required from the equation $x^2 + 13 = 4x$, or $x^2 - 4x = -13$, we ſhould find $x = 2 \pm \sqrt{-9}$; and as it is here neceſſary to extract the ſquare root of -9, which cannot be determined, the queſtion is ſhewn to be impoſſible, or to involve a contradiction.

But although imaginary expreſſions of this kind are of no other uſe in the reſolution of quadratic equations, than to ſhew that a particular problem cannot be ſolved, they muſt not, on this account, be altogether rejected; as they are well known to be of the greateſt uſe in many mathematical inveſtigations, particularly in ſome of the higher branches of the ſcience, where no other mode of reaſoning could be ſo ſucceſsfully or advantageouſly employed.

Thus, if e be made to repreſent the number of which the hyperbolic logarithm is 1, it is well known, as a theorem in trigonometry, that

$$\text{Coſ.}\ x = \frac{e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}}{2}$$

$$\text{Sin.}\ x = \frac{e^{x\sqrt{-1}} - e^{-x\sqrt{-1}}}{2\sqrt{-1}}$$

Where the ſine and coſine of any arc x is exhibited in a very commodious manner, by means of imaginary exponential expreſſions; which formulæ, though objected to, and ridiculed by certain writers, are conſidered, by the celebrated Lagrange (Leçons, ſur des Fonct. Analytiques) as one of the fineſt analytical diſcoveriesof the eighteenth century.

Having thus ſufficiently explained the nature of quadratic equations, it will be neceſſary, before we proceed to the reſolution of cubics and thoſe of higher dimenſions, to ſhew how the ſecond term of any equation may be taken away, in order to fit it for a ſolution; which is done as follows:

Divide the coefficient of the ſecond term of the propoſed equation by the exponent of the firſt term, and add the quotient, with its ſign changed, to ſome new unknown quantity: then if this ſum be ſubſtituted for the unknown quantity in the propoſed equation, a new equation will ariſe, which will want the ſecond term, as required.

For example, let the quadratic equation $x^2 - 8x + 15 = 0$, be that of which it is required to take away its ſecond term.

Then ſince $\frac{8}{2} = 4$, if x be put $= y + 4$, we ſhall have, $x^2 =$

$$\begin{array}{rl} x^2 = & y^2 + 8y + 16 \\ -8x = & \quad -8y - 32 \\ +15 = & \qquad\quad +15 \\ \hline \end{array}$$

Whence $y^2 - 1 = 0$, the equation required.

From which it appears, that any quadratic equation may be ſolved without completing the ſquare, by only taking away the ſecond term; for ſince in the above reduced equation $y = \sqrt{1} = 1$, we ſhall have $x = y + 4 = 1 + 4 = 5$.

Again, let the equation $x^3 - 9x^2 + 26x - 34 = 0$ be given, to exterminate the ſecond term.

Then ſince $\frac{9}{3} = 3$, if x be put $= y + 3$, we ſhall have,

$$\begin{array}{rl} x^3 = & y^3 + 9y^2 + 27y + 27 \\ -9x^2 = & \quad -9y^2 - 54y - 81 \\ +26x = & \qquad\quad +26y + 78 \\ -34 = & \qquad\qquad\quad -34 \\ \hline \end{array}$$

Whence $y^3 - y - 10 = 0$, or $y^3 - y = 10$, the equation required.

In like manner, let the following literal equations of the fourth power $x^4 + px^3 + qx^2 + rx + s = 0$ be given, to exterminate the ſecond term.

Then, by putting $x = y - \frac{p}{4}$, we ſhall have,

$$\begin{array}{rl} x^4 = & y^4 - py^3 + \frac{3p^2}{8}y^2 - \frac{p^3}{16}y + \frac{p^4}{256} \\ px^3 = & \quad + py^3 - \frac{3p^2}{4}y^2 + \frac{3p^3}{16}y - \frac{p^4}{64} \\ qx^2 = & \qquad\quad + qy^2 - \frac{pq}{2}y + \frac{qp^2}{16} \\ rx = & \qquad\qquad\quad + ry - \frac{rp}{4} \\ s = & \qquad\qquad\qquad + s \\ \hline \end{array}$$

Hence $y^4 + \frac{8q - 3p^2}{8}y^2 + \frac{8r - 4pq + p^3}{8}y + \frac{256s - 64rp + 16qp^2 - 4p^3 + p^4}{256} = 0$, the reduced equation required. And the ſame method of ſolution may be applied to the taking away the ſecond term of any equation whatever.

Another ſpecies of transformation, of uſe in reducing equations to their ſimpleſt form, is that of converting ſuch of the terms as have fractional coefficients into others that ſhall be integral; which is done by ſubſtituting a new unknown quantity, divided by the product of all the denominators, inſtead of the unknown quantity in the equation; and then, by proper reductions, the equation will be found to have the form required.

Thus, let $x^4 + \frac{p}{a}x^3 + \frac{q}{b}x^2 + \frac{r}{c}x + \frac{s}{d} = 0$, be the given equation.

Then, if x be aſſumed $= \frac{y}{abcd}$, we ſhall have, by ſubſtitution,

$$\frac{y^4}{a^4b^4c^4d^4} + \frac{py^3}{a^4b^3c^3d^3} + \frac{qy^2}{a^2b^3c^2d^2} + \frac{ry}{abc^2d} + \frac{s}{d} = 0.$$

And by multiplying the whole equation by $a^4b^4c^4d^4$ it will become

$$y^4 + bcdpy^3 + a^2bc^2d^2qy^2 + a^3b^3c^2d^3ry + a^4b^4c^4d^3 = 0,$$

which is of the form required.

This preparation being made, it will now be proper to proceed to the ſolution of *cubic equations*, or thoſe of which the higheſt power is of three dimenſions; all of which, when expreſſed in general terms, are of the form

$$x^3 \pm px^2 \pm qx \pm r = 0.$$

Or, if the ſecond term be taken away, by means of the above-mentioned rule, any equation of this kind may be exhibited under the form

$$x^3 \pm px = \pm q$$

And, in this caſe, the value of the unknown quantity x, according to the rule uſually aſcribed to Cardan, is as follows:

$$x = \sqrt[3]{\tfrac{1}{2}q + \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}} + \sqrt[3]{\tfrac{1}{2}q - \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}$$

Or

$$x = \sqrt[3]{\tfrac{1}{2}q + \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}} - \frac{\tfrac{1}{3}p}{\sqrt[3]{\tfrac{1}{2}q + \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}}$$

the values of p and q being always ſuppoſed to be taken with the ſign + or −1 according as they are found in the given equation.

The rule may be demonſtrated thus:

Let the equation, whoſe root is to be determined, be

$$x^3 + px = q$$

Then if x be aſſumed $= y + z$, we ſhall have, by ſubſtitution,

$$\begin{array}{rl} x^3 = & y^3 + 3yz(y + z) + z^3 \\ px = & \qquad p(y + z) \\ \hline \end{array}$$

$$\text{Or } x^3 + px = y^3 + \overline{3yz + p} \times \overline{y + z} + z^3 = q$$

And if, in this laſt equation, $3yz$ be taken $= -p$, we ſhall have the two following equations for determining the values of y and z: *viz.*

$$\begin{array}{rl} 3yz = & -p \\ y^3 + z^3 = & \quad q \end{array}$$

Where, ſince in the firſt of them, $z = -\frac{p}{3y}$, if this value be ſubſtituted in the ſecond, it will become

$$y^3 - \frac{p^3}{27y^3} = q$$

Or by multiplying by y^3, and then tranſpoſing the terms,

$$y^6 - qy^3 = (\tfrac{1}{3}p)^3$$

And as this equation is now in the form of a quadratic, on account of the index of the higheſt term being double that of the ſecond, we ſhall have, by the rule already given for that purpoſe, and by ſimple equations.

$$y = \sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}$$

$$z = \frac{\tfrac{1}{3}p}{\sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}}$$

Whence $x = y + z = \sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}} - \dfrac{\tfrac{1}{3}p}{\sqrt[3]{\tfrac{1}{2}q \pm \sqrt{(\tfrac{1}{2}q)^2 + (\tfrac{1}{3}p)^3}}}$ as was to be ſhewn.

As a practical application of the rule, let there be given the equation $x^3 + 6x = 20$, to find the value of x.

Thus, if p be put $= 6$, and $q = 20$, the analytical expreſſion will become

$$\sqrt[3]{10 + \sqrt{100 + 8}} - \frac{2}{\sqrt[3]{10 + \sqrt{100 + 8}}} = \sqrt[3]{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}}$$

$$= \sqrt[3]{10 + 10.3923} - \frac{2}{\sqrt[3]{10 + 10.3923}} = \sqrt[3]{20.3923} - \frac{2}{\sqrt[3]{20.3923}}$$

$$= 2.732$$

$= 2.732 - \frac{2}{2.732} = 2.732 - .732 = 2$, which is the required value of x.

It happens, however, that the value of the unknown quantity is here only found by approximation; but this, when the root is a whole number, may always be avoided, for ſince in the preſent inſtance, $\sqrt[3]{10 + \sqrt{108}} = 1 + \sqrt{3}$, as may be proved by raiſing it to the third power, if this be ſubſtituted in its proper place, in the above expreſſions, we ſhall have $\sqrt{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}} = 1 + \sqrt{3}$

$$- \frac{2}{1+\sqrt{3}} = \frac{(1 + \sqrt{3})^2 - 2}{1+\sqrt{3}} = \frac{1 + 2\sqrt{3} + 3 - 2}{1+\sqrt{3}}$$

$= \frac{2 + 2\sqrt{3}}{1 + \sqrt{3}} = 2$, as before.

Again, as a ſecond example, let there be given $x^3 - 6x = - q$, to find the value of x.

Here $p = - 6$ and $q = - q$

Then, by ſubſtituting theſe values in the above formula, we have

$$x = \sqrt[3]{-4\tfrac{1}{4} + \sqrt{20\tfrac{1}{2} - 8}} - \frac{-2}{\sqrt[3]{-4\tfrac{1}{4} + \sqrt{20\tfrac{1}{2} - 8}}}$$

$$= \sqrt[3]{-4\tfrac{1}{2} + 3\tfrac{1}{2}} + \frac{2}{\sqrt[3]{-4\tfrac{1}{2} + 3\tfrac{1}{2}}} = \sqrt[3]{-1} + \frac{2}{\sqrt[3]{-1}}$$

$= -1 + \frac{2}{-1} = - 1 - 2 = - 3$, the required value of x.

But as a quadratic equation has been ſhewn to have two roots, or values, of the unknown quantity, ſo, in like manner, it may be proved that the unknown quantity, in a cubic equation, has three values or roots, each of which will be found to anſwer the conditions of the queſtion.

Thus, in the firſt equation $x^3 + 6x - 20 = 0$, given above, where x has been found $= 2$, or $x - 2 = 0$, if $x^3 + 6x - 20 = 0$ be divided by $x - 2$, we ſhall have $x^2 + 2x + 10 = 0$, or $x^2 + 2x = - 10$, the roots of which equation, found according to the rule for quadratics, are $- 1 + 3\sqrt{-1}$, and $- 1 - 3\sqrt{-1}$, each of which, as well as the former root 2, are values of the unknown quantity, as will be found by ſubſtituting them for x in the given equation.

It muſt be obſerved, however, that neither the formula of Cardan, nor any other that has yet been diſcovered, will be found ſufficient to determine the numerical value of the unknown quantity in every cubic equation that can be propoſed; for when the coefficient of the ſecond term of the equation is negative, and the cube of $\frac{1}{3}$ of it is greater than the ſquare of half the abſolute term, the expreſſion for the root becomes imaginary; and therefore no intelligible reſult can be derived from it.

Thus, if the equation propoſed, were $x^3 - 3x = 1$, the analytical expreſſion, when converted into numbers, will become $x = \sqrt[3]{\frac{1}{2} + \sqrt{\frac{1}{4} - 1}} - \frac{1}{\sqrt[3]{\frac{1}{2} + \sqrt{\frac{1}{4} - 1}}} =$

$\sqrt[3]{\frac{1}{2} + \frac{1}{2}\sqrt{-3}} - \frac{1}{\sqrt[3]{\frac{1}{2} - \frac{1}{2}\sqrt{-3}}}$, the value of which cannot be determined either in integers, fractions, or rational ſurds; although, by ſubſtituting it for x in the given equation, the terms will all vaniſh as they ought; and conſequently, in a certain ſenſe, it may be ſaid to be a root of the equation.

This defective ſtate of Cardan's formula, or that in which it fails as a general rule, has commonly been called the *irreducible caſe of cubic equations*; and notwithſtanding the reiterated efforts of the moſt celebrated analiſts in Europe, from the time when the want of generality in the rule was firſt obſerved, to the preſent day, no remedy has been found for this defect, except by a method of ſolution which is derived from the triſection of an angle, or by converting the expreſſion into an infinite ſeries; in which latter caſe that part of the quantity which is imaginary diſappears, and by that means enables us to compute the root to any degree of exactneſs. For it is to be remarked, that although the unknown quantity cannot be determined from the formula itſelf, yet all the three roots are, in this caſe, real, and can be found, at leaſt approximately, by either of the two methods laſt-mentioned.

Leaving this part of the ſubject, for the preſent, we ſhall next proceed to *biquadratic equations*, or thoſe of the fourth power; any one of which, when the ſecond term is taken away, may be repreſented, in general terms, by $x^4 + ax^2 + bx + c = 0$; and the rule for the reſolution of any equation of this form, is as follows:

Find the value of y in the cubic equation $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$, by the rule before given for this purpoſe; and let the root, thus determined, be denoted by v.

Then find each of the values of x in the two following quadratic equations,

$$x^2 + (\sqrt{v - \tfrac{2}{3}a})x = - [\tfrac{1}{2}a + \tfrac{1}{2}(v - \tfrac{2}{3}a)] + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

$$x^2 - (\sqrt{v - \tfrac{2}{3}a})x = - [\tfrac{1}{2}a + \tfrac{1}{2}(v - \tfrac{2}{3}a)] - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

And the values of x, thus found, will be the four roots of the biquadratic equation $x^4 + ax^2 + bx + c = 0$, as was required.

The rule, which is here given in a more commodious form than that of Des Cartes, may be readily demonſtrated, by making the given equation $x^4 + ax^2 + bx + c = 0$, equal to the product of two quadratic equations, and then equating the coefficients of the homologous terms. Thus, if $x^2 + px + q$ be multiplied by $x^2 - px + r$, and the product thence ariſing put $= 0$, we ſhall have $x^4 + (r + q - p^2)x^2 + p(r - q)x + rq = 0$.

Hence $r + q - p^2 = a$, $p(r - q) = b$, and $rq = c$; and conſequently $2r = a + p^2 + \frac{b}{p}$, and $2q = a + p^2 - \frac{b}{p}$.

And if theſe values be ſubſtituted in the equation $rq = c$, or its equal $4rq = 4c$, we ſhall obtain, after proper reduction, the equation $p^6 + 2ap^4 + (a^2 - 4c)p^2 = b^2$.

Or, by putting $p^2 = y - \frac{2}{3}a$, and ſubſtituting it in the latter equation, we ſhall have for the reſult the cubic equation $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$, which is that given in the rule.

Hence, if the value, or root of y, in this equation, be put $= v$, we ſhall have, from the equations given above, $p = \sqrt{v - \frac{2}{3}a}$, $q = \frac{1}{2}a + \frac{1}{2}(v - \frac{2}{3}a) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$, and $r = \frac{1}{2}a + \frac{1}{2}(v - \frac{2}{3}a) + 2\sqrt{v - \frac{2}{3}a}$. And by, ſubſtituting theſe values in the two quadratic equations $x^2 + px + q = 0$, and $x^2 - px + r = 0$, they will become $x^2 + \left(\sqrt{v - \frac{2}{3}a}\right) x = -\frac{1}{2}a - \frac{1}{2}\left(v - \frac{2}{3}a\right) + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$, and $x^2 - \left(\sqrt{v - \frac{2}{3}a}\right) x = -\frac{1}{2}a - \frac{1}{2}\left(v - \frac{2}{3}a\right) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$; the roots of which equations will be the 4 roots of the propoſed biquadratic equation $x^4 + ax^2 + bx + c = 0$. As a practical example for the exerciſe of this rule, let there be given $x^4 - 6x^2 - 16x + 21 = 0$, to find the 4 values of x.

Then, if the numbers -6, -16, and 21 be ſubſtituted in the place of a, b, c, in the cubic equation $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$, it will become $y^3 - \frac{36 + 252}{3}y = 256 - \frac{12}{27}(36 - 756)$, or $y^3 - 96y = 576$, where the value of y, as determined by the preceding rule for cubic equations, will be found $= 12$.

Hence, if 12 be put for v, -6 for a, and -16 for b, in the two quadratic equations,

$$x^2 + \left(\sqrt{v - \tfrac{2}{3}a}\right) x = -\tfrac{1}{2}a - \tfrac{1}{2}\left(v - \tfrac{2}{3}a\right) + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

$$x^2 - \left(\sqrt{v - \tfrac{2}{3}a}\right) x = -\tfrac{1}{2}a - \tfrac{1}{2}\left(v - \tfrac{2}{3}a\right) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

they will become,

$$x^2 + \left(\sqrt{12 + 4}\right) x = 3 - 8 - 2 = -7$$
$$x^2 - \left(\sqrt{12 + 4}\right) x = 3 - 8 + 2 = -3$$

Or,

$$x^2 + 4x + 7 = 0$$
$$x^2 - 4x + 3 = 0$$

In the firſt of which $x = -2 + \sqrt{-3}$, or, $-2 - \sqrt{-3}$. And in the ſecond, $x = 3$ or 1, which are the roots of the given equation $x^4 - 6x^2 - 16x + 21 = 0$; there being always as many values of the unknown quantity, in any equation, as there are units in the index of its higheſt power; as will be ſhewn in a ſucceeding part of this article.

But before we proceed to any enquiries of this kind it will be proper to obſerve, that no general rule has hitherto been found for reſolving equations of the 5th, 6th, or other higher orders, notwithſtanding the numerous attempts that have been made for this purpoſe; ſo that in this reſpect we have not been able to advance a ſingle ſtep beyond what had been done by Louis Ferrari, Bombelli, and others in the early part of the 17th century, who were all acquainted with the method of reſolving biquadratic equations; which is ſtill the boundary that the moſt ſkilful analiſts, aſſiſted by all the advantages of a more comprehenſive and commodious calculus, have not been able to paſs.

But although no general reſolution has hitherto been given of equations higher than thoſe of the 4th power, there are, notwithſtanding, ſome particular equations, of all orders, which, on account of certain relations ſubſiſting between the coefficients of their different terms, may be reſolved by the rules which have been given for thoſe of the firſt four orders.

This is particularly the caſe with what have been uſually called *reciprocal equations*, which are ſuch that the coefficients of the terms form the ſame numerical ſeries, whether taken in a direct or an inverted order; or that remain the ſame when the reciprocal of the unknown quantity, or $\frac{1}{x}$ is ſubſtituted for x.

Thus, for example, the equations $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$, $x^4 + px^3 + qx^2 + px + 1 = 0$, &c. which are of this kind, may always be transformed into others of a degree denoted by half the exponent of the higheſt power of the unknown quantity, if it be an even number, or by half the exponent diminiſhed by 1, if it be an odd number.

Thus, let the laſt of the two equations given above, $x^4 + px^3 + qx^2 + px + 1 = 0$, be taken in the form $x^2 + \frac{1}{x^2} + p\left(x + \frac{1}{x}\right) + q = 0$, to which it can be readily reduced; then if $x + \frac{1}{x}$ be put $= z$, we ſhall have $x^2 + 2 + \frac{1}{x^2} = z^2$, or $x^2 + \frac{1}{x^2} = z^2 - 2$; and if this be ſubſtituted in the original equation $x^4 + px^3 + qx^2 + px + 1 = 0$, it will become $z^2 + pz = 2 - q$. And ſince $x + \frac{1}{x} = z$, we ſhall have $x^2 - zx + 1 = 0$. Hence, if the two roots of the equation $z^2 + pz = 2 - q$, be denoted by r and r', we ſhall have the two following equations $x^2 - rx + 1 = 0$, and $x^2 - r'x + 1 = 0$; the roots of which will be the four roots of the given biquadratic equation $x^4 + px^3 + qx^2 + px + 1 = 0$.

And in a ſimilar way may any other equation of this kind be reſolved, when the index of the greateſt power of the unknown quantity is an even number.

And if the index of the unknown quantity be an odd number, as in the equation $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$, it is obvious from inſpection only, that -1 is a root of the equation; and, conſequently, if $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$, be divided by $x + 1$, it will be reduced to the form $x^4 + (p - 1)x^3 - (p - q - 1)x^2 + (p - 1)x + 1 = 0$, which is another reciprocal equation, a degree lower than the former; and having the index of its higheſt power an even number, it is conſequently reſolvible in the manner above explained.

Alſo, when two or more roots of any equation are equal to each other, the equation may always be reduced to another of an inferior degree, and the roots, by that means, determined.

Thus, if the cubic equation $x^3 - px^2 + qx - r = 0$, has two equal roots, each of them will be $x = \frac{pq - qr}{p^2 - 6q}$.

For, let the three roots be denoted by a, a and b; then by the compoſition of equations we ſhall have $x^3 - (2a + b)x^2 + (a^2 + 2ab)x - a^2b = 0$; where $2a + b = p$, $a^2 + 2ab = q$, and $a^2b = r$; and if theſe values be ſubſtituted in the above form, it will become $x = \frac{pq - qr}{p^2 - 6q} = \frac{2a^3 + 4a^2b + a^2b + 2ab^2 - 9a^2b}{8a^2 + 8ab + 2b^2 - 6a^2 - 12ab} = \frac{2a^3 - 4a^2b + 2ab^2}{2a^2 - 4ab + 2b^2} = a$, as was to be ſhewn.

Thus, let the equation $x^3 + 5x^2 - 32x + 36 = 0$, which has two equal roots, be the one propoſed to be reſolved.

Then ſince $p = -5$, $q = -32$, and $r = -36$, if theſe values be ſubſtituted in the formulæ $x = \frac{pq - qr}{p^2 - 6q}$, it will become $x = \frac{-5 \times -32 - 9 \times -36}{2 \times 25 - 6 \times -32} = \frac{160 + 324}{50 + 192} = \frac{484}{242} = 2$, which is one of the equal roots of the equation.

And in a ſimilar manner may the equal roots of equations of the higher orders be determined; but though the ſubject conſidered as a branch of analyſis is highly curious, and on that account has been far more completely and ſcientifically inveſtigated than in the caſe here given, its practical importance is too trifling to render any farther elucidation of it neceſſary, in an article ſo confined as the preſent. The ſame may alſo be ſaid of the method uſually given for determining the roots of an equation by means of the diviſors of its laſt term, and other ſimilar proceſſes, which are moſtly tentative, and only adapted to the finding ſuch roots of the equation as are rational, and for that reaſon readily diſcovered by a few trials.

It remains, therefore, only to ſhew how the roots of any numeral equation whatever may be determined by approximation; for which purpoſe, it will be ſufficient to give the rule firſt employed by Newton and Ralphſon, which, though attended with ſome defects, is as commodious, when conſidered as a general method of ready and eaſy application, as any one that has yet been propoſed. The rule is as follows.

Find, by trial, a number nearly equal to the root required, which call r; and let z be put equal to the difference between r and the true root x.

Then, inſtead of x in the given equation, ſubſtitute its equal $r \pm z$, and there will ariſe a new equation, affected only with z, and known quantities.

This done, reject all thoſe terms in which there are two or more dimenſions of z, and the value of z will then be found by means of a ſimple equation.

And if the value of z, thus found, be added to, or ſubtracted from, that of r, according as r was aſſumed too great or too little, it will give the root required *nearly*.

And if this root ſhould not be thought ſufficiently near the truth, the operation muſt be repeated, by ſubſtituting the laſt reſult inſtead of r, in the equation exhibiting the value of z; by which a ſecond correction of the root will be obtained more accurate than the former, and ſo on to any degree of exactneſs required.

As a practical example, for the illuſtration of the rule, let there be given the equation $x^3 + x^2 + x = 90$, to find the value of x by approximation.

Here it is ſoon found, by a few trials, that the root is ſomething greater than 4.

Let, therefore, $4 = r$, and $r + z = x$, then,

$$\begin{aligned} x^3 &= r^3 + 3r^2z + 3rz^2 + z^3 \\ x^2 &= r^2 + 2rz + z^2 \\ x &= r + z \end{aligned}$$

And conſequently by rejecting the terms $z^3 + 3rz^2 + z^2$, we ſhall have $r^3 + 3r^2z + r^2 + 2rz + r + z = 90$;

or, $z = \dfrac{90 - r^3 - r^2 - r}{3r^2 + 2r + 1} = \dfrac{90 - 64 - 16 - 4}{48 + 8 + 1} = \dfrac{6}{57} = .10$, and $x = 4 + .10 = 4.1$, nearly.

And again, if 4.1 be ſubſtituted in the place of r, in the laſt equation, we ſhall have.

$z = \dfrac{90 - r^3 - r^2 - r}{3r^2 + 2r + 1} = \dfrac{90 - 68.921 - 16.81 - 4.1}{50.43 + 8.2 + 1} = \dfrac{78.121}{59.63} = .00283$; and $x = 4.1 + .00283 = 4.10283$.

And by proceeding in this manner, the root may be obtained to any degree of accuracy required.

The chief defect in this rule is, that it does not ſhew the progreſs made in the approximation at each operation, and that when the roots are ſmall and ſome of them nearly equal to each other, they may be paſſed over, by this method of operating, without their being perceived; both of which circumſtances have been particularly noticed by Lagrange, who has given an improved method of approximation in his excellent work on the "Réſolution des Equations Numériques," to which we muſt refer the reader, as being but little ſuſceptible of that kind of conciſe elucidation which neceſſarily belongs to an article like the preſent.

It, therefore, only remains to give ſome account of the general theory of equations; in which it will be firſt neceſſary to ſhew, that every equation, of any order whatever, has as many roots as there are units in the index of the higheſt power of the unknown quantity in that equation.

For this purpoſe, let us take the general equation $x^n + Px^{n-1} + Qx^{n-2} \ldots\ldots + Tx + U = 0$, to which all others can be readily reduced: then if a root of this equation be denoted by a, the firſt ſide of it will be diviſible by $x - a$.

For, ſince $x^n + Px^{n-1} + Qx^{n-2} \ldots + Tx + U = 0$.

And $a^n + Pa^{n-1} + Qa^{n-2} \ldots + Ta + U = 0$.

Therefore, by ſubſtraction, $(x^n - a^n) + P(x^{n-1} - a^{n-1}) + Q(x^{n-2} - a^{n-2}) \ldots T(x - a) = 0$.

But any expreſſion of the form $(x^n - a^n)$, where n denotes any whole poſitive number, is $= (x - a) \times (x^{n-1} + ax^{n-2} + a^2x^{n-3} \ldots a^{n-2}x + a^{n-1})$, as may be readily proved by multiplication. Whence, if the quantities $x^n - a^n$, $x^{n-1} - a^{n-1}$, $x^{n-2} - a^{n-2}$, &c. be each divided by $x - a$, we ſhall have

$$\begin{array}{rrrrr} x^{n-1} + a\,x^{n-2} & + a^2 x^{n-3} & \ldots\ldots & + a^{n-1} \\ & x^{n-2} + a\,x^{n-3} & \ldots\ldots & + a^{n-2} \\ & + \quad x^{n-3} & \ldots\ldots & + a^{n-3} \\ & & \ldots\ldots\ldots\ldots & \\ & & & + 1 \end{array}$$

Or, if the ſame expreſſions be arranged according to the powers of x, they will become

$$\begin{array}{rrrr} x^{n-1} + a\,x^{n-2} & + a^2 x^{n-3} & \ldots\ldots & + a^{n-1} \\ + P\,x^{n-2} & + P\,a\,x^{n-1} & \ldots\ldots & + P\,a^{n-2} \\ & + Q\,x^{n-1} & \ldots\ldots & + Q\,a^{n-3} \\ & \ldots\ldots\ldots\ldots & & \\ & & & + T \end{array}$$

Where, by putting $P' = a + P$, $Q' = a^2 + aP + Q$, &c. we ſhall have $x^n + Px^{n-1} + Qx^{n-2} \ldots + Tx + U = (x - a) \times (x^{n-1} + P'x^{n-2} + Q'x^{n-3}$, &c.$) = 0$.

And if b be ſuppoſed to be a root of the equation $x^{n-1} + P'x^{n-2} + Q'x^{n-3}$, &c. $= 0$, the former of theſe will become $x^n + Px^{n-1} + Qx^{n-2}$, &c. $= (x - a) \times (x - b) \times (x^{n-2} + P''x^{n-3} + Q''x^{n-4}$, &c.$)$; which latter equation may be ſhewn to have a ſimilar factor, $x - c$; and by proceeding in the ſame manner, the original equation may be decompoſed into as many factors, $x - a$, $x - b$, $x - c$, $\ldots\ldots\ldots\ x - l$, as there are units in the exponent n of its higheſt term.

Hence, by conſidering equations as formed by the product of certain factors, $x - a$, $x - b$, $x - c$, &c. we are enabled to diſcover a number of relations which ſubſiſt between its roots and coefficients.

Thus ſuppoſing a, b, c, d to be the roots of the biquadratic equation $x^4 + px^3 + qx^2 + rx + s = 0$, if this be repeſented by its factors $(x - a) \times (x - b) \times (x - c) \times (x - d) = 0$, we ſhall have, by multiplying them together, $x^4 - (a + b + c + d)x^3 + (ab + ac + ad + bc + bd + cd)x^2 - (abc + abd + acd + bcd)x + abcd = 0$; and by proceeding in the ſame manner, a ſimilar reſult may be obtained for any equation whatever.

Hence, from the bare inſpection of this equation, the following conſequences are readily derived.

1. The coefficient of the ſecond term of any equation, taken with a contrary ſign, is equal to the ſum of all the roots of that equation.

2. The coefficient of the third term is equal to the

ſum of the products of all the roots, multiplied together, two by two.

3. The coefficient of the fourth term, taken with a contrary ſign, is equal to the ſum of the products, of all the roots, multiplied together, three by three; and ſo on to the laſt term, which is equal to the product of all the roots with contrary ſigns.

From this it alſo follows, that in an equation wanting its ſecond term, there muſt be both poſitive and negative roots, and that the ſum of the former is equal to that of the latter.

And in the ſame way, a number of other properties of the various orders of equations may be derived, which will be found of great uſe, not only with reſpect to their reſolution, but as furniſhing the materials for a complete inveſtigation of this curious and intereſting branch of analyſis.

We ſhall only farther add, that beſides the ſimple factors into which any equation may be decompoſed, it may likewiſe be produced by multiplying together factors of any degree, provided the ſum of their dimenſions be equal to that of the propoſed equation.

For the application of the principles and rules, illuſtrated in the preceding article, to the ſolution of arithmetical, geometrical, and other queſtions and problems, we refer to REDUCTION of *Equations*, APPLICATION of *Algebra*, &c.

EQUATION, in *Aſtronomy*, is a term uſed to expreſs the correction, or quantity, to be added to or ſubtracted from the mean poſition of a heavenly body, to obtain the true; it alſo, in a more general ſenſe, implies the correction ariſing from any erroneous ſuppoſition whatever. *E. g.* The time of noon, determined by taking equal altitudes of the ſun, is firſt obtained by ſuppoſing the ſun's declination conſtant during the whole interval, which falſe ſuppoſition is corrected by an appropriate equation. Moſt of the principal equations will be found under their different articles, in the various tables to which they belong.

EQUATIONS, *Conſtruction of.* See CONSTRUCTION *of Equations.*

EQUATIONS, *Converſion of.* See CONVERSION *of Equations.*

EQUATIONS, *Abſolute, adfected* or *affected, differential, eminential, exponential, fluential, fluxional, literal, numeral,* and *tranſcendental.* See the adjectives.

EQUATION *of a Curve,* is an equation ſhewing the nature of a curve, by expreſſing the relation between any abſciſs and its correſponding ordinate, or elſe the relation of their fluxions, &c. Thus, the equation for the circle is $ax - x^2 = y^2$, where a is its diameter, x any abſciſs or part of that diameter, and y the ordinate at that part of the diameter; and the equation denotes, that whatever be the abſciſs expreſſed by x, the ſquare of its correſponding ordinate will be $ax - x^2$. Thus alſo the equation for the ellipſe is $\frac{p}{a} \times \overline{ax - x^2} = y^2$; for the hyperbola $\frac{p}{a} \times \overline{ax + x^2} = y^2$; and for the parabola $px = y^2$; in all which a is an axis, and p the parameter. This method of expreſſing the nature of curves by algebraical equations was firſt introduced by Des Cartes, who, by thus connecting together the two ſciences of algebra and geometry, made them naturally ſubſervient and auxiliary to each other, and thus laid the foundation of the moſt conſiderable improvements that have been made in every branch of them ſince that time. See APPLICATION of *Algebra*, &c. See alſo CURVE.

EQUATION *of Payments,* in *Arithmetic,* is the method of reducing ſeveral debts payable at different times, and bearing no intereſt till after the term of payment of a ſingle debt or payment, to be diſcharged at once, without loſs either to debtor or creditor, allowing ſimple intereſt; or, it is the method of finding the equated term at which theſe ſeveral debts ſhould be paid in one ſum. Cocker, Hatton, Kerſey, ſir Samuel Moreland, and Ward, have given rules for this purpoſe, which Mr. Malcolm has examined and found to be erroneous; and though the error reſulting from any of the rules which they have propoſed is not very conſiderable, the following proceſs furniſhes one more accurate.

Let the debt firſt payable be called	d	The laſt payable debt	D
The diſtance of the term of payment	t	The diſtance of the term	T

The diſtance of the equated time x

The rate of intereſt, or 1 year's intereſt of 1*l.* r

The diſtance of the time t and x is $x - t$
The diſtance of the time T and x is $T - x$ } for x lies between them.

Then the intereſt of d for the time $x - t$ is $dr \times x - t$, or $drx - drt$, dr being one year's intereſt of d; and $\frac{DTr - Drx}{1 + Tr - rx}$ is the diſcount of D for the time $T - x$, becauſe $Tr - rx$ is the intereſt of 1*l.* for that time, which is conſequently the diſcount of $1 + Tr - rx$ for the ſame time; conſequently, from the nature of the queſtion, we ſhall have $drx - drt = \frac{DTr - Drx}{1 + Tr - rx}$; which being reduced, gives $T + t + \frac{D + d}{dr} \times x - x^2 = \frac{DT + dt}{dr} + Tt$. Then make $T + t + \frac{D + d}{dr} = a$, and $\frac{DT + dt}{dr} + Tt = s$, and $ax - x^2 = s$; and reſolving this quadratic equation, $x = \frac{a}{2} \pm \sqrt{\frac{a}{4} - s}$.

E. gr. Suppoſe 100*l.* payable one year hence, and 105*l.* payable three years hence; what is the equated time, allowing ſimple intereſt at 5 *per cent. per annum?*

Here $\begin{matrix} d = 100 \\ t = 1 \end{matrix} \left\{ \begin{matrix} D = 105 \\ T = 3 \end{matrix} \right\} \; r = .05.$

Then $D + d = 205$, $dr = 5$, and $\frac{D + d}{dr} = \frac{205}{5} = 41$.

And $T + t + \frac{D + d}{dr}$, or $a = 4 + 41 = 45$.

And s or $\frac{DT + dt}{dr} + Tt = \frac{315 + 100}{5} + 3 = 83 + 3 = 86$. Conſequently,

$x = \frac{45}{2} \pm \sqrt{\frac{2025}{4} - 86} = \frac{45}{2} \pm \sqrt{506.25 - 86} = 22.5 \pm \sqrt{420.25} = 22.5 \pm 20.5 = 43$ or 2: but 43 cannot be the true anſwer by the conditions of the queſtion, ſince it is greater than the diſtance of the laſt term in the queſtion; and therefore 2 is the anſwer required.

If there are more debts than two you muſt firſt find an equated time for the two that are firſt payable; then conſider their ſum as a debt payable at that equated time, and find another equated time for that debt and the next of the given debts, &c. See Malcolm's Arithm. book vi. § 5. or p. 616—621.

EQUATION *of the Centre.* This is the firſt and moſt conſiderable of all the equations that are applied to the mean motion of a planet. It ariſes immediately from the nature of the ellipſe. If the orbit of a planet was perfectly circular it would have no equation of the centre; and a ſpherical body, revolving round a centre of force in an elliptic orbit, undiſturbed by the motion of other bodies, would require no other equation to correct its mean motion than the equation of the centre.

The neceſſity of applying this equation to the motion of the ſun, in its apparent orbit, was known to the early aſtronomers; for, in fact, no very accurate obſervations were neceſſary to ſhew that the ſun did not perform equal parts of its annual motion in equal portions of time. When, by means of gnomons, the length of the year and the obliquity of the ecliptic were pretty well eſtabliſhed, it muſt have been eaſy, with the ſame inſtrument, to have obſerved the declination of the ſun every day, and from thence to have computed its longitude. The firſt aſtronomers who undertook this examination muſt naturally have expected to find a regular increaſe in the ſun's longitude for every day in the year; but when they found that in the courſe of three months the obſerved longitude differed near two degrees from that which they had computed, it became then evident, that if the ſun's orbit was circular, and its motion uniform, at leaſt the earth was not placed in the centre of it.

This difference, which we now call the equation of the centre, was named by the ancient aſtronomers προσθαφαιρεσις, from προσθεσις, *addition*, and αφαιρεσις, *ſubtraction*, becauſe this equation is ſometimes additive and ſometimes ſubtractive, a name almoſt applicable to all equations, but applied to the equation of the orbit as the moſt conſiderable of all. Hipparchus was acquainted with this unequality in the motion of the ſun, which had not long been diſcovered before his time. He obſerved, that from the equinox of ſpring to the ſummer ſolſtice, there was an interval of $94\frac{1}{2}$ days, and from the ſolſtice to the next equinox $92\frac{1}{2}$ days; that is, two days leſs, notwithſtanding theſe points were equally 90° from each other. The motion of the ſun in two days is $1^\circ\ 58'$, which is nearly the quantity of the greateſt equation. To explain this difference, and to aſſign the exact proportion to every day in the year, the ancient aſtronomers either placed the earth out of the centre, at a ſufficient diſtance to produce the greateſt equation, or imagined an epicycle to revolve upon the circular orbit, on whoſe circumference the ſun was ſuppoſed to move. Theſe ſuppoſitions would give the ſun's longitude near enough the truth to ſatiſfy the imperfect obſervations of thoſe days, and when ſimilar unequalities were obſerved in the moon and planets, new cycles and epicyles were invented to explain them. But theſe contrivances, however ingenious, had very little pretenſion to be claſſed as theories or hypotheſes, capable of giving a ſatiſfactory explanation of the cauſes of theſe phenomena. An ingenious mechanic may make a clock, that ſhall repreſent all the inequalities of ſolar time, and by a proper application of ſome very ſimple principles in practical mechanics, we may repreſent the moſt complicated ſyſtem of motions; yet theſe machines would give us no inſtructions as to the original motions which they imitated; and in proportion as they became complicated, ſhould we be the leſs inclined to ſuppoſe any reſemblance between their mechaniſm, and that of the motions they repreſented.

Nevertheleſs, in the ſimple caſe that we are now conſidering, had obſervation accurately agreed with the ſuppoſition, there would have been no reaſon for not admitting it; it would have reſted on the ſame ground as Kepler's elliptic hypotheſis, before Newton had demonſtrated how obviouſly it is derived from one general law of nature.

For the method of calculating the greateſt equation of excentric orbits, we refer the reader to De la Lande's Aſtronomy, vol. ii.

We ſhall here only explain the nature of this equation in an orbit perfectly elliptical. The equation of the orbit of a planet is evidently nothing at the apſides; beginning to reckon from the aphelion it augments rapidly; as the true or real motion being there the ſloweſt, differs moſt from the mean motion, it continues to increaſe, but leſs and leſs rapidly, till the planet has arrived at ſome point about three ſigns, and ſomething more from the aphelion, at which point the true and mean motions are equal. At this time the equation is the greateſt, it begins then ſlowly to diminiſh, and the diminution becomes more and more rapid, as it approaches the perihelion, at which time the real motion exceeds the mean motion by the greateſt quantity. When it arrives at the aphelion the equation is again nothing. In the ſame manner it increaſes again to a maximum, and then diminiſhes till its return to the aphelion, where it is again nothing. The equation is ſubtractive in the firſt ſix ſigns from the mean motion, and additive in the others.

The greateſt equation may be derived directly from obſervation; or if the excentricity be known it may be computed, and at the ſame time the degree of anomaly in which it happens. For this purpoſe it is ſufficient to find the point M (*Plate* XII. *Aſtronomy, fig.* 107.) where the planet is at its mean diſtance. For it is evident, that the moment the planet arrives at the point where its angular velocity D F M is equal to its mean velocity, the mean longitude will ceaſe to gain upon the true longitude, but their difference will be a maximum; becauſe till that moment the real velocity, which was leaſt, had continually cauſed the mean velocity to accelerate upon the true, but from the moment they are equal, the real velocity begins to accelerate upon the mean, and to regain the quantity which it had before loſt: from this time the true and mean place approach each other, and the equation begins to diminiſh. Thus the problem conſiſts in finding the point M, and the true anomaly A F M of the planet, at the moment that its true velocity is equal to the mean angular velocity.

Take F M a mean proportional between the two ſemi-axes of the orbit. With the focus F as a centre, and diſtance F M, deſcribe a circle M N, which circle will have a ſurface equal to the ellipſe. Suppoſe a body to deſcribe uniformly this circle in the ſame time in which the planet deſcribes its ellipſe, its angular velocity will always be equal to the mean angular velocity of the planet in the ellipſe; and the area deſcribed in the circle will be always equal to the area deſcribed in the ellipſe, becauſe the planet always deſcribes equal areas in equal times. For example, if the planet deſcribes in one day an area D F R $=\frac{1}{365}$ th part of the elliptic ſurface, the area E F O, deſcribed in the circle, will likewiſe be the $\frac{1}{365}$th part of the area of the circle; and the real velocity of the planet, or the angle D F R, will be equal to the mean velocity in M, that is, to the angle E F O; for there are two equal ſectors having the ſame length E M, the ſame ſurface, and conſequently the ſame angle. Beſides the equal triangles M E D, M R O, which are the one without, and the other within the circle, ſhew that the elliptic ſector is preciſely equal to the circular ſector, that has the ſame angle in F. Therefore to find the point of the mean velocity, we muſt find at what degree the interſection of the ellipſe correſponds with the circle equal to it in ſurface. From the point M let the ſtraight line M B be drawn to the other focus of the ellipſe, then in the triangle B E M three ſides will be known; namely, B F, which is the double of the excentricity, F M, which is the mean proportional between the two ſemi-axes, and B M, which is the difference between

F M, and the greater axis, becauſe the two lines E M and M B are together equal to the greater axis. By reſolving this triangle the angle F may be found, which will be the true anomaly of the planet, at the time of its greateſt equation.

In the caſe of the greateſt equation, the reſolution of the above triangle gives the following rule. From the aphelion diſtance take ſeparately the mean proportional of the two ſemi-axes, and the third ſide B M (difference between the greater axis and the mean). Take the logarithms of theſe differences, and ſubtract the leaſt from the greateſt; from this difference take the difference of the logarithms of the aphelion and perihelion diſtances; the half of the remainder is the logarithmic tangent of half the true anomaly. By the method of coſines take the logarithms of the aphelion diſtance, and of the difference of the ſide B M; add the complements of the logarithms of B E and F M, the half of the ſum is the logarithmic coſine of half the true anomaly. If the angle is ſmall, this method of the coſines is leſs exact; but when the angle is large, it is preferable to the other, being ſomewhat ſhorter.

Having thus deſcribed the method of calculating the greateſt equation, we have now to conſider the manner of obſerving it.

From the inſtant a planet departs from its aphelion A, to the time it arrives at the point M of its greateſt equation, its real velocity is leſs than its mean velocity; therefore, the true anomaly is leſs than the mean anomaly, and differs from it more and more. When the planet has paſſed the point P, or its perihelion, and arrives at the point G, having about nine ſigns of anomaly, its true diſtance A F G from the aphelion is in the ſame manner leſs than its mean diſtance, by a quantity equal to the greateſt equation. If we obſerve two true longitudes of the planet in G and M, they will differ from each other by the angle G F M, which is the ſum of two true anomalies: but the ſum of two mean anomalies will be greater by the double of the equation, ſince each true diſtance is leſs than the mean diſtance by the whole of the equation. It is eaſy to calculate the ſum of two mean anomalies without knowing the place of the aphelion A, becauſe the ſum of two mean anomalies is equal to the mean motion of the planet for this interval of time, which is found by taking its proportion of the whole revolution: thus, the exceſs of the mean motion, calculated over the true diſtance obſerved, will be double the greateſt equation, provided the two obſervations are made in M and G, the times that the mean velocities equal the true. It will, on the contrary, be the true or obſerved motion that will exceed the mean, if the obſervations are taken on each ſide the perihelion. To determine the time and the obſervations moſt ſuitable to this inveſtigation, an obſerver, who ſhould be ſuppoſed to have no previous knowledge of the ſituation of the orbit, muſt begin by collecting a great number of obſerved poſitions, and compare them two and two together, and obſerve how much the obſerved motion differs from the mean for each interval: in this manner the greateſt of the obſerved diſtances will be found double the greateſt equation; but if this compariſon is made with a ſingle obſervation, then the greateſt difference additive and the greateſt ſubtractive, added together, will give double the equation. But ſince at preſent we know very nearly the place of the apſides, and of the mean diſtances of all the planets, we can immediately ſelect the obſervations that are made about the time of the greateſt equation.

Example.—The 7th October, 1751, the place of the ſun obſerved by La Caille, was, after three ſucceſſive obſervations

	6'	13°	47′	13″.7
And the 28th March, 1752	0	8	9	25.5
The difference is	5	24	22	11.8
The mean motion calculated for this interval is	5	20	31	43.2
Difference, or double the equation	0	3	50	28.6
The half is the equation required	0	1	55	14.3

This would be exactly the greateſt equation, if the obſervations had been made exactly at the moment of the greateſt equation; but having calculated by the tables theſe equations, it was found that 18″.6 muſt be added to have the greateſt equation, which will make the above quantity 1° 55′ 33″.

With reſpect to this 18″.6 it may be remarked, that an error of ſeveral minutes in the equation of the tables would have produced no ſenſible alteration in this correction, as the error would be the ſame for the given day as for the greateſt of all which happened extremely near it.

As it is extremely rare to meet with two obſervations which are preciſely ſituated in the two points M and G of the mean time, ſo it is not eaſy to find by the firſt calculation the exact value of the equation; but after having found it very nearly, and likewiſe the place of the apſide, the equation may be calculated for the times of obſervation, and likewiſe the greateſt equation; by the method explained above, it may be then ſeen how much the equation derived from the obſervations ſhould differ from the greateſt. It was by this means that La Caille, in the preceding example, found the above correction 18″.6. The greateſt equation of the ſun is that which may be obſerved the moſt frequently, and with the greateſt eaſe. A perſon ſtudying aſtronomy, and deſirous of making himſelf converſant with the methods by which all theſe elements of the planetary motions have been obtained, may deduce them himſelf from the Nautical Almanac, or other ſimilar publications; he may regard the longitudes and latitudes of the planets there found as ſo many obſervations, and by computing from them, the original elements ſhould be found, from which the tables themſelves were calculated. If the minutes and ſeconds be omitted, or the neareſt half or quarter of a degree only taken, they will repreſent the obſervations of the early aſtronomers, and it will then be ſeen what very imperfect theories were ſufficient to explain ſuch inaccurate obſervations.

Theſe methods of finding the greateſt equation cannot be applied to Mercury, as we never can obſerve its heliocentric longitude but when on the ſun's diſc. Its elongation, and that of Venus, is found by obſerving the greateſt digreſſion when the planet is in the apſides. For a farther account of this method conſult De la Lande's Aſtronomy.

Caſſini employed the tranſits of Mercury obſerved in 1661, 1690, and 1697, and found the greateſt equation 24° 3′. De la Lande, from the tranſits of 1740, 1743, and 1753, found 23° 27′ 51′. But theſe obſervations are not well ſuited, as the three points of the orbit are not diſpoſed at diſtances ſufficiently great. The equation of the centre does not remain for ever the ſame; by compariſon with ancient obſervations the equation of the earth's orbit appears to have undergone a diminution, and the theory of attraction explains the cauſe, and aſſigned the quantity more correctly than can be obtained by obſervation. La Place makes the diminution for the earth's orbit 0°.0058 decimals in a century;

tury ; this phenomenon ſuppoſes a correſponding diminution in the excentricity, for if the excentricity was nothing, the equation would be nothing. The correſponding diminution of the excentricity is 0.000045553, the ſemi-axis major being taken as unity.

This is nearly equal to 1548 French leagues in a century, or 40 Engliſh miles in a year. Thus, fractions which appear inſenſible in the heavens, become conſiderable when compared with our known meaſures. If this diminution was always progreſſive, the ſolar ellipſe would in time be changed into the circumference of a circle, and in the end, the excentricity decreaſing always, the earth, after a great number of ages, would fall into the ſun ; but the theory of attraction indicates that the variation in the equation of the orbit and excentricity are periodic, and that after having diminiſhed for a certain period, they will again increaſe and take the ſame values they had before, and will thus oſcillate within narrow limits ; but the periods of theſe oſcillations are ſtill unknown, and thus the ſyſtem might be eternally maintained, except ſome exterior and unknown cauſe ſhall come to change the ſyſtem of the world, and new-modify its laws.

Table of the greateſt Equation of the Centre according to different Aſtronomers.

Equation, *Secular, of the Mean Motion of the Moon.* The motion of the moon, and its elements, do not remain conſtant, but undergo progreſſive alterations, which would ſoon render the tables inaccurate, if we were obliged to improve merely by compariſon with recent obſervations. The only method of avoiding this inconvenience is to calculate the elements of the lunar motion for different periods very remote from each other, to deduce the variations they have undergone, and then to inveſtigate the laws proper to repreſent them.

We may apply theſe conſiderations to the mean and ſecular motion of the moon, which has been determined with great exactneſs by modern obſervations, and which ſerves as a baſis for all the other reſults, and compare it with ancient obſervations, to ſee if it is the ſame, or if it has materially changed. The method of making this compariſon conſiſts in conſidering the ancient obſervations of the moon as ſo many obſerved longitudes ; the place of the moon is then calculated by the tables for this diſtant epoch, and the reſult compared with the obſervation.

The moſt ancient eclipſe upon record may be taken as an example. It was obſerved by the Chaldeans 721 years before the Chriſtian era, and recorded by Ptolemy. The obſervation was made at Babylon the 19th March : the moon began to be eclipſed about an hour after its riſing. At the middle of the eclipſe the longitude of the moon was equal to that of the ſun ; this latter is eaſy to calculate by the ſolar tables ; thus the longitude of the moon is given at the period of the eclipſe. Now, if the place of the moon be calculated by the tables for this epoch, it will be found leſs advanced in its orbit, than it muſt have been by the obſervation : the difference is about one degree and a half ; and as this is too great an error to be attributed to the inaccuracy of the tables, we muſt conclude that the motion of the moon is now accelerated : ſo that in referring it to a diſtant period, we throw it too far back in its orbit, which diminiſhes its longitude.

And this reſult acquires additional confirmation, by making ſimilar compariſons with obſervations made at intermediate periods ; for if the motion of the moon is really accelerated, we ſhould ſtill find the longitude calculated by the tables too ſmall, though the error ſhould be leſs as the interval is ſmaller ; and this appears to be the caſe by a ſimilar compariſon with an eclipſe obſerved at Cairo by Ibn-junis, an Arabian aſtronomer of the 10th century.

This coincidence leaves no doubt as to the reality of the phenomenon ; and it appears certain, that the motion of the moon has accelerated from the time of the Chaldeans to the Arabians, and from that time to the preſent. To repreſent this acceleration, a third term, proportional to the time, muſt be added to the ſecular motion of the moon, and another leſſer term proportional to the cube ; this, together, is what is called the ſecular equation of the moon. According to La Place, (Mecanique celeſte, vol. iii. p. 273.) if n be the number of centuries elapſed ſince 1750, the formula for the correction will be $31''.424757\, n^2 + 0''.05721742\, n^3$. Theſe ſeconds are according to the decimal diviſion.

But we are not to infer that this acceleration will always be increaſing, or that the preceding formula will always repreſent it ; the theory of attraction, in making known the cauſe, has ſhewn that it is periodic, and connected with the variations of the excentricity of the terreſtrial orbit. See Excentricity, and Equation *of the Centre*.

This acceleration, after increaſing to a certain limit, will be changed into a retardation, but the extent of this period is very conſiderable ; and the interval, which ſeparates us from the moſt ancient obſervations, has yet only developed an extremely ſmall part of this revolution. The inequalities which will reſult in the motion of the moon will amount at leaſt to a 40th part of the circumference of her orbit. Poſterity, who will obſerve theſe great phenomena, may remark, and not without gratitude, that the geometricians of the preſent age have foreſeen, calculated, and prepared for their ſucceſſors the means of judging of the paſt and future ſtate of the ſyſtem of the world, with the ſame certainty as in the age in which they lived.

It was the celebrated Dr. Halley who firſt diſcovered the effects of this acceleration ; and La Place, by a moſt profound

found analyſis, has explained both the cauſe and the law. The obſerver and the geometrician are each entitled to admiration. If the reſult of the latter is more ſatisfactory and uſeful to ſcience, it muſt be confeſſed, that it was a proof of no ſmall ſagacity in the former to be the firſt to doubt of the uniformity of the mean motions which had been admitted as an eſtabliſhed principle for above two thouſand years.

Equations, *Secular, which affect the Elements of the Orbit of the Moon.* The motion of the lunar perigee is not uniform, but ſubject to a ſecular equation analogous to that of the mean motion, and depending on the ſame cauſe. The compariſon of ancient obſervations with the modern leaves no doubt of this fact; but it is to the theory of attraction that we are indebted for the diſcovery. This equation is equal to that of the mean motion, multiplied by the coefficient -3.00052, that is to ſay, that if k repreſent the ſecular equation of the mean motion, the term $-3.00052k$ muſt be added to the mean longitude of the perigee, calculated from the duration of a tropical revolution. Mec. celeſte, vol. iii. p. 247.

The motion of the nodes is likewiſe ſubject to a ſimilar inequality, and the equation has the ſame ſign as that of the perigee, it is equal to the equation of the mean motion multiplied by -0.735452, that is, to the mean longitude of the node add $-0.735452\,k$. Theſe reſults are confirmed by obſervation.

It appears from this, that the ſecular equation diminiſhes the longitude of the perigee and of the nodes when it augments the mean motion of the node, and reciprocally; hence the motion of the perigee and of the nodes becomes ſlower, when that of the moon is accelerated, and on the contrary is accelerated when that of the moon is retarded. Moreover, theſe inequalities are connected together by very ſimple analogies, ſince they are repreſented by the numbers 1; 3.00052; -0.735452.

The anomaliſtic revolution, depending at the ſame time on the motion of the moon and of the perigee, is likewiſe modified by the ſecular variation. It is the ſame with all the quantities which depend on the apogee, and on the nodes.

The theory of attraction indicates, that the diſtance of the moon from the earth, the excentricity, and the inclination to the orbit, are equally ſubject to ſecular equations, which are connected with that of the mean motion. But hitherto their effect is ſcarcely perceptible; nevertheleſs, in the courſe of ages, it will become neceſſary to attend to them, and they have been calculated in advance. The expreſſion for the greater axis of the orbit contains no inequality of this kind. This likewiſe is the reſult of theory. The cauſe of all theſe extremely curious facts has been explained by La Place, who was led to them by the diſcovery of the original cauſe which produced the ſecular equation of the moon. For the ſecular equations of the other celeſtial bodies, ſee their reſpective names, and Secular.

Equation-*Clock*, in *Horology*, is a clock contrived ſo as to indicate both *mean* and *equated* ſolar time, and conſequently their difference, which at any inſtant is the *equation of time.* Various contrivances have been invented to anſwer this purpoſe by ingenious men, who at one time were ſeized with a rage for inventing ſuch uſeleſs appendages of the clock, but the dictatorial power of faſhion has nearly baniſhed ſuch ſuperfluities, that are now conſidered as mere matters of curioſity. For a deſcription of a clock of this ſort by Enderlin, ſee our article Clock, and *Plate* XXIV. of *Horology*.

Equation-*Mechaniſm*, in a planetarium or orrery, is a mechanical contrivance for repreſenting the alternate accelerations and retardations of motion in the requiſite parts of the reſpective orbits of the different planets, which contrivance has been variouſly effected by different ingenious men. If the motions of the heavenly bodies had been in concentric circles, and perfectly equable in every point of their orbits, the conſtruction of a common planetarium would have been well calculated to exhibit all the phenomena in a natural and exact manner, provided the trains of wheelwork were accurately calculated for the reſpective periods, and the length of the arms proportional to the reſpective diſtances; but as all the planets that have conſiderable excentricity, and conſequently conſiderable equations of the centre alternately *plus* and *minus*, have their motions conſtantly varying in angular velocity, a common planetarium, without equation-mechaniſm, is a very imperfect machine, and by no means competent to ſolve any of the phenomena, in a particular way, that depend on the relative velocities; for when the heliocentric motions are improperly repreſented, the geocentric appearances depending on them are deranged, and no dependance can be placed in the *times* pointed out of the apparent conjunctions, oppoſitions, ſtations, retrogradations, longitude, or latitude of any of the heavenly bodies. For inſtance Mercury, which planet performs its period through the ecliptic in ſomewhat leſs than 88 days, inſtead of continuing 44 days in each half of its orbit, at oppoſite ſides of the conjugate axis, as it does reſpectively in thoſe at each ſide of the tranſverſe axis, continues about $55\frac{1}{2}$ days in the aphelion portion, and only $32\frac{1}{2}$ in the perihelion portion, ſo that the times of conjunction with the earth or other planet, even allowing the motion of that planet to be equable, would from this cauſe alone become very irregular, exceeding or falling ſhort of the mean ſynodic period by many days, according to circumſtances. It is evident, therefore, that the variations of velocity depending on the equation of the centre of both orbits of two planets, one received from the other, require to be taken into conſideration, and allowed for in the conſtruction of any mechaniſm that profeſſes to be accurate in the repreſentation of planetary motion.

Contrivances by Mr. Huygens.—The earlieſt attempt that we have met with, to produce the requiſite inequalities of planetary motion by mechaniſm, is that of Mr. Huygens, the Dutch mathematician and philoſopher, which he has deſcribed in his Latin treatiſe on the conſtruction of his *Automaton*, or ſelf-moving planetarium; he has availed himſelf of two different applications of the ſame principle, that are reſpectively applicable to different degrees of inequality of motion, that the excentricity of an orbit may require; his account and demonſtration of both which methods we ſhall give in a free tranſlation from his own words, which will probably be intereſting to thoſe who cannot read the original, particularly as there has been no notice taken of them by any writer, or inſtrument-maker, except perhaps Rowley, during the laſt century.

"It remains now," ſays our very ingenious author, "that we explain how the true anomalies may be repreſented by wheelwork; for this purpoſe let A N P, *fig.* 1. of *Plate* III. of *Planetary Machines*, be the orbit of a planet, the centre of which is C with the ſun at S, and let the point E be taken any where in the line S C, ſo that the excentricity S C may be to the radius C A, as C E is to E D; with which radius and centre E let the circle D M be deſcribed. Now let it be underſtood, that upon the centre of the circle A L there be fixed immoveably the contrate wheel D M with equal teeth, which therefore will neceſſarily revolve round the point C as a centre; let it be alſo ſuppoſed that the arbor of the long pinion K H be directed to C, and turned equally with its teeth adapted to thoſe of the wheel D M, which will agree ſufficiently, although on account of the excentricity of this wheel it will not always have the pinion at right angles; by this motion, I ſay, a planet will be carried unequably in its orbit, and in ſuch a manner that its motion will very nearly correſpond to Kepler's hypotheſis. For having taken in the circle D M, deſcribed from the point E, any arc D O, let the teeth of that arc paſs over to the line C D by turning the pinion K H, and the line C O will coincide with the line C A D, but not ſo that the point O may fall on the point D, but within at R, becauſe C D, which is equal to both C E and E O, is greater than C O: now whatever may be the angle O C D, ſuch will be that over which the line C A D has moved round the centre C; therefore if we make the angle D C T equal to the angle D C O, C T will be the right line into which C A D will have advanced, ſo that the planet will have proceeded from A to the point N, where the right line C T cuts the circumference of the circle A N deſcribed from the centre C. But the circle D M, having its centre E advanced to F by making F T equal to E D, will have the ſame ſituation as the circle T R: and it appears that on account of the equality of the angles O C D and D C T, the arc D M, which the right line C T cuts in the circumference of O D M, is equal to the arc D O; ſo that M and E being joined, the angle M E D will be equal to D E O. If, therefore, the arc A L be made to contain as many degrees as the arc D M, and C F be joined, this line will be parallel to E M.

"In the triangles C E M and S E L, therefore, the angles L C S and M E C will be equal, and the ſubtending ſides proportional; for by conſtruction S C is to C L, as C E is to E M, C L being equal to C A, and E M to E D. Alſo the angles M C E and L S C are equal, and conſequently the lines C M and S L are parallel.

"Now by this rotation of the circles D M and A L, the planet placed in A will be moved through the circle A L, very nearly according to Kepler's hypotheſis, as may be thus ſhewn. Let the planet be ſuppoſed to have moved from A to N, the ſpace or area N S A will be equal to its mean anomaly; but ſeeing the lines S L and C N are parallel, the triangles N S C and C L N will be equal, at leaſt their difference will be inſenſible; the ſpace or area, therefore, C L A, and conſequently the arc A L, will anſwer to the mean anomaly when the planet has advanced from A to N. If, however, we make A Q P the elliptic orbit of Kepler, the planet will be in Q, where the perpendicular N Q falling on A P cuts the ellipſe A Q P, and not in N; but the ellipſes are ſo like circles, that the variation in a machine is imperceptible, N will, therefore, be the true place of the planet correſponding to the mean motion A L, which arc is equal to D O or D M.

"Again, if the pinion be placed in any other point, as at G, equally diſtant from the centre C, to which the arbor is directed, and the point D, which is the moſt diſtant from the centre C, in the wheel O D M, be placed under the pinion, the planet being again at its aphelion A, it appears that the ſame angles are formed round the centre C by an equable motion of the pinion placed in G as in D. Wherefore in whatever ſituation the pinion be placed, the motion of the planet will be unequable, notwithſtanding the teeth of the wheel D M are made equal among themſelves, provided the pinion that points to the centre C have its teeth made long enough to act with all the teeth of the wheel which come ſucceſſively to it at different diſtances from the centre C, and provided that the planet be put to its aphelion point of its orbit, when the longeſt line, or radius, drawn from C to D M, is in contact with the pinion.

"But ſince in our machine (automaton) all the pinions are placed on one common arbor, it cannot be placed properly towards the centres of more than two planets; we muſt, therefore, conſider how the ſame effect can be produced by *unequal teeth*: for this end let us ſuppoſe the circle D M divided into the equal parts D *a*, *a b*, *b* M, and M *g*, and right lines be drawn to them from the point C, theſe lines C *a*, C *b*, C M, C *g*, will divide A N L, the orbit of the planet, into the unequal parts A *d*, *d e*, *e* N, N *f*. By this method as many unequal teeth may be determined in the circle A N L, as there are equal ones in the circle D M. If now the pinion be applied to theſe teeth, cut into the ſame number as in the former caſe, they will work together pretty well, though ſome are too large and others too ſmall for the pinion, and the wheel A N will move unequably as the wheel D M did before, which has been proved to be according to the hypotheſis of Kepler."

This is a faithful tranſlation of Mr. Huygens' account and demonſtration of his two methods of repreſenting the irregularities of a planet's motion in its orbit, concerning which we have to obſerve, that, though both of them manifeſt great ingenuity as to the originality of the projects, yet they fall ſhort of producing ſeparately that full effect which he attributes to them, and which he ſeems to have credited; whereas the truth is, that inſtead of effecting the *whole* equation of the centre, the methods juſt deſcribed effect each only *one half* thereof; for agreeably to Kepler's theory, which ſuppoſes equal areas in equal times, biſhop Ward has proved that *double the excentricity* of a planet's orbit ſubtends very nearly its greateſt equation, and that, according to his elliptic hypotheſis, which is an excellent approximation to the truth, if the angular velocity of a planet round one focus of the ellipſe be uniformly equable, its angular velocity, as ſeen from the other focus, will be ſo unequable, that one will repreſent the mean and the other the true or equated anomaly very nearly; but the diſtance between the two foci of any ellipſe is its excentricity laid off both ways from the centre, or *doubled*; whereas the method of Mr. Huygens' propoſes the excentricity to be taken only *once*, ſo that he has demonſtrated rightly enough, but from wrong data; for if he had made the diſtance C E equal to double the excentricity, then the whole of the equation would have been very nearly repreſented. The demonſtration which Mr. Olinthus Gregory of Woolwich, then of Cambridge, has given in the 2d vol. of Mr. Nicholſon's Philoſophical Journal of the 8vo. ſeries, to which we beg leave to refer, has proved with great perſpicuity what the Rev. W. Pearſon of Parſon's Green had before aſſerted, that "the excentricity of any planet's orbit is very nearly equal to the ſine of one half only of its greateſt equation." It may be conſidered as a ſingular circumſtance that a man of Mr. Huygens' genius and mathematical ſkill, whoſe whole life was devoted to the ſciences, ſhould not diſcover that the methods which he ſo ingeniouſly deviſed to exhibit a planet's equated motion, produced but one half of the grand equation; and equally ſingular, perhaps, may it be conſidered, that no one before the writer of this article has detected the deficiency. When both theſe methods of conſtructing a planetary wheel are *united*, the full effect will be produced; or either of them may be united with any other contrivance that produces only one half the equation.

Mr. Roemer's Contrivance.—The next contrivance that we have met with, for repreſenting planetary motion, is that of Roemer, who was mathematician to the king of France in the time of Mr. Huygens; this contrivance is detailed in Mr. Nicholſon's Journal, vol. 4. of the 4to. ſeries, by a correſpondent, who tranſlated his account from the French of "Machines and Inventions approved by the Royal Academy of Sciences for 1699," and who, in our opinion, ſpeaks better of it than it deſerves. The plan propoſed might anſwer for one planet only, but is not applicable to a number of planets at the ſame time, for the planetary wheel propoſed is intended to be ſo thick as to conſtitute the fruſtum of a cone, on the ſurface of which a diagonal elliptical line is to be drawn round it, from the ſmaller to the larger diameter and back again, in which line the teeth are to be formed, after they have been laid down by a pair of dividers from a diagram previouſly made; ſo that, ſetting aſide the tediouſneſs of making ſuch a wheel by the mechanical manipulation deſcribed; there could not be a number of theſe wheels brought into action by any of the uſual arrangements of wheelwork, ſeeing the pinions that are to act with them muſt neceſſarily be conical alſo, and be the drivers in every caſe, which the requiſite calculations of the trains in planetary machines will not always admit, where the extreme ratios of relative velocity are ſo widely different from each other. This plan, therefore, of exhibiting unequable motion in a planetarium, or orrery, muſt be conſidered among thoſe projects of ingenuity which are more plauſible in theory than ſerviceable in practice, and no doubt was abandoned for the reaſons that have been here ſtated; which are our reaſons for paſſing over it without further notice.

Dr. Deſaguliers' Contrivance.—The next mechaniſm in the order of time, as far as we know, was Dr. Deſaguliers' elliptic pulleys, or oval wheels with grooves at the circumference, and an endleſs cat-gut ſurrounding them, as deſcribed under our article COMETARIUM. This was certainly a ſcientific contrivance, and admits of application where the excentricity of the orbit is great; for the excentricity and ſhape of the pulleys may be made exactly ſimilar to the excentricity and ſhape of the orbit to be repreſented. The principal objection to the adoption of this invention in a planetarium, is the liability of the cat-gut to contract and elongate with the variations of moiſture in a room, and conſequently to be ſometimes too tight for the pulleys, and ſometimes too looſe, ſo as not to perform their office of giving motion to the elliptic plates. We have ſeen the elliptic plates with their edges cut into teeth, which is a great improvement in the contrivance; and where the excentricity is not very great, a pair of excentric circular wheels will act together very well, to anſwer the ſame purpoſe, as we ſhall have occaſion to ſhew preſently.

Mr. Adam Walker's Contrivance.—Another method of exhibiting planetary motion we have witneſſed in the philoſophical lectures of Mr. Walker, ſenior, which, if we recollect perfectly, was effected thus: A wooden board was ſhapen nearly into the form of an epicycloid, and had equal teeth cut on its circumference by hand, with an arm fixed faſt to one of its extremities, that carried the ſtem of a planet, or of a ball to repreſent a planet; then a pinion was fixed on the ſurface of an inclined plane, down which the epicycloidal wheel was ſuffered to ſlide by its own weight, in a detached ſtate, till its teeth came in action with the teeth of the pinion; and a motion given to the pinion by a handle, made the wheel, thus circumſtanced, to revolve with unequal velocities, accordingly as its central point was near to, or removed from, the pinion, during its revolution in this ſliding ſtate; thus were not only the accelerations and retardations of motion alternately exhibited, but alſo the variations of diſtance, as they regarded the ſun's ball fixed in the focus of an elliptical board, placed over this mechaniſm, and divided into twelve triangular areas, ſo that the planetary body was ſeen to move through the twelve ſectors, coloured alternately white and black, in a manner correſponding to the ſame number of revolutions of the pinion; and to perform apparently equal areas in equal times. It is hardly neceſſary to obſerve on this contrivance, that, however convenient it might be to illuſtrate in a general way the nature of planetary motion to an audience, it is obvious that detached wheels acting thus at liberty cannot be introduced into any machine that gives motion to a ſyſtem of bodies, where their apſides croſs one another in various directions, and would require as many inclined planes as there are planets to be repreſented; likewiſe the planetary arms would require to be attached to *wheels* in every inſtance, though the calculations of the ratios of velocity might, and, according to the general conſtructions, would require in ſome inſtances *pinions* to be the laſt movers; all which difficulties in practice are inſurmountable. The *ſhape* of the planetary wheel, we have underſtood, was not determined geometrically, nor yet by calculation, but by a repetition of manual rectifications of the figure till it was found to correſpond with the areas previouſly delineated.

Mr. Joſeph Prieſtley's Contrivance.—When Dr. Birbeck was appointed profeſſor to ſucceed the late Dr. Garnet, at Anderſon's Univerſity in Glaſgow, his friend, Mr. Joſeph Prieſtley of Bradford, contrived an orrery, which was made for him by a watch-maker at Halifax, of the name of Thomas Liſter, which orrery the doctor has lately brought with him to London, on quitting the ſaid profeſſorſhip. It was finiſhed in the year 1801, and will be deſcribed in its proper place with the other planetary machines. The inequalities of motion in this machine are produced by two ſeparate methods; the two ſuperior planets Saturn and Jupiter have their equations effected by inequalities made in the teeth of the laſt moving wheels; but the others have their equations, with the exception of the earth, produced by a contrivance which is at the ſame time novel, ſimple, and accurate enough for mechanical repreſentation. The inventor has been kind enough to comply with our requeſt of his giving us an account of his mode of producing unequable motion by mechaniſm, which account we ſhall preſent to our readers in his own words. The figure to which he refers, is *fig.* 2. of *Plate* III. of *Planetary Machines.*

Let A P B, ſays Mr. Prieſtley, be the orbit of the planet, O its centre, and S and F the two foci; in the former of which the ſun is ſuppoſed to be placed. On the other focus F, as a centre, deſcribe a circle D E *p*.

Let P be any given place of the planet in its orbit; draw F *p*, cutting the circle D E *p* in *p*. Now, agreeably to the hypotheſis of Ward, it will be,

As the periodical time of the planet,
Is to the time of its paſſing from A to P;
So is 360 degrees,
To the angle E F *p*.

Hence, if a point *p* be made to revolve equably in the circle D E *p*, deſcribed on the lower focus F of the orbit, performing one revolution in the periodical time of the planet; and if, at any given time, the point be found at *p*, then a line drawn from the focus F through *p*, will cut the orbit of the planet in P, its place at the ſame time.

There are different ways of adopting this hypotheſis in machinery. The firſt I ſhall mention, will immediately occur to any one viewing the figure. Let a wire, ſomething longer than F B, be made to revolve equably round F, in the time repreſenting one revolution of the planet. On this wire let a ſtud P be made to ſlide freely, and confined to move in the orbit A P B; then the motion of the ſtud will, very nearly, repreſent that of the planet.

In the conſtruction of an orrery, where each planet will require a ſeparate arm F *p*, moveable on its peculiar centre, with the ſlider P confined to its own orbit, it may not be eaſy to contrive the whole ſo as to prevent one part of the machinery from interfering with another; nor can this method be conveniently uſed, where the wheels carrying the arms are rims. The following conſtruction has been found to anſwer the intention, and the motion to be very free and regular.

Let E *p* D be the toothed rim moving equably, the time of a revolution repreſenting that of the planet. This rim may have any convenient diameter, not differing greatly from the orbit. Upon this rim, or on any projection attached to it, is fixed a pin C, round which one end of a bar C P moves; on the other end of the bar is fixed a perpendicular wire, or ſtem P, which carries the planet. This ſtem is confined to move in the orbit A P B; and, during its revolution, is made to riſe and fall, ſo as to ſhew the inclination of the orbit to the ecliptic. The bar C P may be made of any convenient length; and the pin C ſhould be ſo ſituated, that when P is at *p*, the bar becomes a tangent to the circle E *p* B. This is neceſſary, that the end P, in its vibrations on C, may be always found, as nearly as poſſible, in the line F *p*; and on this account, the length of the bar ſhould be as great as circumſtances will conveniently admit.

Contrivances by the Rev. William Pearſon.—Some time previouſly to the year 1796, the Rev. William Pearſon, who lived at that time in the city of Lincoln, had read the accounts of Mr. Benjamin Martin's and Mr. James Ferguſon's planetary mechaniſm with ſuch attention, as enabled him to diſcover many imperfections in them, which it appeared to him might be avoided, and among the reſt that defect which ariſes from equable motion and unvarying diſtance. On entering into a correſpondence with one of the inſtrument-makers in London, he found that the modern machines owed their origin chiefly to one or the other of the above-named authors, and that little or no improvement had been made in the accuracy of their repreſentations ſince their time. In conſequence of this information, and unacquainted with the contrivances we have juſt deſcribed, except that of Dr. Deſaguliers, deſcribed by Mr. Ferguſon, he turned his mind towards the ſubject with a view of deviſing ſome improvements in this kind of machinery, which required an union of mechanical ſkill, with a knowledge of the ſcience of aſtronomy, to enable him to ſtrike out original plans for the accompliſhment of his purpoſe. His firſt object was to render the trains of wheel-work as nearly as poſſible ſuch as would produce the true periods of the different planets in their orbits, in doing which he found no difficulty after he had adopted a direct and unerring ſyſtem of calculation, which became eaſy and familiar by practice; but this part of his purſuit is not the object of our preſent article: the next object of his attention was to deviſe the mechanical means of exhibiting planetary motion, both with regard to variable velocity and variable diſtance; different methods preſented themſelves in ſucceſſion at different times, ſome of which he afterwards found had been tried before by others, but the firſt project that promiſed to be really ſubſervient to his purpoſe was that which was repreſented in *fig.* 3. of *Plate* III. of *Planetary Machines*, and which was made for the arm of Mercury, in an orrery conſtructed under his direction, by a clock-maker at Lincoln. The contrivance had three objects in view, the variable diſtances, the variable velocities, and the latitudes of the planets, or deviation from the ecliptic, two of which purpoſes it anſwered moſt completely, and the third in a certain degree, beſides preſerving, fourthly, the paralleliſm of the planet's axis in every part of its orbit. It occurred to the contriver of the mechaniſm in queſtion, before he had ever ſeen Mr. Adams's "Geometrical and Graphical Eſſays," and before he had heard of "Suardi's Geometric Pen," that if a ſmall arm were by any means made to revolve in a retrograde direction, when placed at the diſtant end of the long arm, or radius vector of any planet, during the time that the radius vector itſelf revolved juſt once by a direct motion round the ſun in the centre, the curve traced by a pencil placed at the remote end of the ſmall arm would be *an excentric circle*; and alſo that there would be an alternate acceleration and retardation of angular velocity in the pencil with reſpect to the ſun, or central point round which the radius vector might be carried; which velocity would be the quickeſt when the pencil was in its neareſt ſituation, and ſloweſt when moſt remote; becauſe in the former caſe, the compound motion would be the ſum of two motions, both in the ſame direction, and in the latter the difference of two motions in contrary directions. This idea, having at the moment of its occurrence made a ſtrong impreſſion on the mind of the inventor, excited in him much impatience to have it brought to the practical teſt of an experiment; the ſmall frame, ſhewn in *fig.* 3, was roughly put together, and the equal wheels A, B, and C, were included, ſo that A was faſt to the arbor S, but B and C revolved on their arbors in the frame; the arbor of the latter, however, was left long enough for its pivot to protrude downwards, and to receive a crank-piece P, bearing a ſhort pencil: the ſtem or arbor S, having its conical point at S fixed on a ſheet of paper, was then held faſt by a milled nut above it, to prevent its revolving, and the frame was carried round while the three ſmall wheels, with equal numbers of teeth, were connected together; the conſequence was, as had been expected, that the pencil traced a circle of a diameter equal to twice the diſtance of the arbors A and C from each other, but the centre of the circle was found to be at G inſtead of S, juſt the length of the ſhort arm or crank-piece P, from the point S, from which the excentric circle was deſcribed. This fact determined at once that the frame and ſhort arm ought to be to each other in length as the mean diſtance is to the excentricity of the orbit of any planet thus to be deſcribed, and, as orbits with but little excentricity are very nearly *excentric circles*, a circle thus deſcribed cannot be diſcriminated in a machine from an ellipſe of the ſame excentricity.

Before we proceed to deſcribe the mechaniſm reſulting from the principle of a little arm revolving backwards on the end of the radius vector of any planet juſt once in each revolution of the planet, let us illuſtrate the principle itſelf more clearly. Suppoſe the line A C, in *fig.* 4. of *Plate* III. to repreſent the length of the frame or radius vector S C, and alſo the ſhort arm C A, repreſenting the excentricity or diſtance from the centre to the focus of the orbit, to be both directed into one right line S A, before any motion be communicated to the frame; then as the teeth of the three wheels A, B, and C, of equal numbers of teeth, are connected together, and the wheel A is at reſt, the wheel B will have a motion in the ſame direction as the frame, and the wheel C will have its motion in a contrary direction, but of the ſame velocity; conceive the centre of the wheel C to be carried along the circumference of the concentric circle C O I E, the ſpace of the quadrant C O, this wheel C by means of its connection with the wheel A, through the medium of wheel B, will in the ſame time have made a quarter of a revolution, and the remote end of the ſmall arm attached to this wheel will be at N, at right angles to the radius vector, after having paſſed along the quadrant A N, of the excentric circle A N P E, of which the point G is the inviſible centre, and during the whole continuance of theſe two equal but contrary motions of the radius vector and ſhort arm, through theſe quadrants reſpectively, the latter will have preſerved itſelf parallel to its original ſituation A C; again, while the radius vector is moving through the three remaining quadrants of the concentric circle from O to I E and C, ſucceſſively, the remote end of the ſmall arm will deſcribe the three correſponding quadrants of the excentric circle from N to P, M, and A, in equal portions of time, and its paralleliſm will ſtill be preſerved throughout the whole circle, as ſeen in the figure. Thus, while the centre of the wheel C deſcribes the concentric circle C O I E round the point S with an equable motion, the remote end of the ſmall arm, ſuppoſed to carry a planetary body, will deſcribe the excentric circle A N P M, during the whole of which time the motion of the planet will be equable as it reſpects the point G or centre, but unequable as it reſpects the point S out of the centre, where the ſun is ſuppoſed to be placed: for conceive lines like S N to be drawn from S to the planet in different parts of the circle A N P M, or orbit, and they will interſect the circle C O I E *behind* the remote end of the radius vector in one half of a revolution, and *before* it in the other, and the angle at S, ſubtended by the ſhort arm in any ſituation, will expreſs the *equation of the centre* in that point of the orbit, which equation, therefore, is *additive* to the mean motion of the radius vector in one ſix ſigns of anomaly, and *ſubtractive* from it in the other ſix. The nature of the alternate retardation and acceleration of motion produced by this mechaniſm round the point S, and alſo the variation of diſtance, may be eaſily apprehended by attending to the ſucceſſive retrograde and direct motions of the arm in each revolution of the radius vector; from A to N theſe move in oppoſite directions, and the difference of their velocities, as viewed from S, is equal to the quantity of retardation in any particular point of this quadrant; at N the difference is nothing, in which ſituation of the arm the equations would be a *maximum* if the arm were perpendicular to the line S N, *i. e.* if S N were a tangent, to the circle of which the arm O N is radius; but this will not happen till the radius vector has advanced beyond the ſpace of an exact quadrant, and the arm has come to *n*, where the angle ſubtended at S by the arm will be the greateſt poſſible.

The diſtance of this point, where the equation is a maximum from 90° of mean anomaly, will evidently depend on the relative proportions in length of the radius vector and ſhort arm, or which is the ſame thing, of the mean diſtance and excentricity of the planet to be repreſented. From *n* to P, through the remainder of the firſt ſemi-circle, the radius vector and arm will both move in the ſame direction, and will cauſe an acceleration which will be greateſt at P, the perihelion point, where they will both be again in a right line, ſhortened by double the whole length of the ſhort arm, as compared with the original ſituation at the aphelion point. From the perihelion to the point of greateſt equation at the oppoſite ſide of the orbit, the motions of the radius vector and arm continue to be in the ſame direction, but through the laſt quadrant and a ſmall portion of the third, the directions are again oppoſite till the planet arrives at the aphelion point A, where it has undergone all its changes of velocity and diſtance, and where it commences the ſame alternation of ſlow and quick motions that were before exhibited.

Thus, if S be conſidered as the ſun, A the place of the aphelion of any planet, P its perihelion, *m* and *n*, in the ſmall circle of the arm, the places of mean motion, the concentric circle C O I E the ecliptic, and the excentric one A N P M the planet's orbit, it is evident that both the excentricity, and alſo a *certain equation* of the centre of a planet's orbit, may be very conveniently repreſented by the ſame apparatus that has long been uſed for no other purpoſe but that of preſerving the paralleliſm of its axis.

But ſtill the main queſtion is not diſpoſed of; *viz.* what portion of the equation, conſidered as an arc of the orbit, will a line equal to the excentricity ſubtend? The analogy for reſolving this query is as follows:

As the mean diſtance, or radius vector, of the planet,
Is to radius,
So is the excentricity, or ſhort arm,
To the ſine of the greateſt angle at S ſubtended by the ſhort arm.

This angle, taken in degrees and minutes, we find is invariably, as nearly as may be, *one-half of the greateſt equation*, as has been already mentioned.

It will now have occurred to the reader, probably, that, if a line equal to the excentricity ſubtends one-half the equation of the centre of a planet, *double* the excentricity will be the meaſure of a ſhort arm that will ſubtend the *whole* equation; this is nearly true as to the queſtion of the equation alone, but then the diſtances and excentricity of the orbit, on which the geocentric appearances depend, would be greatly out of proportion; and what is gained in the heliocentric apparent places would be loſt in the geocentric appearance in the ſyſtem. To keep all the deſiderata within their due bounds, and to make the elements of the orbit accord with both heliocentric and geocentric appearances in the mechanical repreſentation, an additional contrivance was ſuperadded, which ſupplied the defect of the revolving ſhort arm without deranging materially the effect of its operation; the laſt wheel of the train, which carries the radius vector round in the due period, had its teeth ſo unequally cut as to repreſent the ſecond half of the equation, by cauſing an alternate acceleration and retardation in the revolution of the radius vector itſelf, ſo that the total effect produced by theſe two contrivances acting together was very nearly agreeable to the real motion of the planet itſelf in its own orbit. But we have ſaid, that the latitude of the planet was repreſented by the ſame contrivance that ſhews the diſtances and one-half of the equation. This was done by placing the ſtem of the planet in a ſquare ſocket, at the remote end of the ſmall arm, in ſo detached a way, that it was at liberty to reſt on the plane of an inclined plate, carried by the radius vector, to repreſent the inclination of the orbit, and to receive the circular ſcale of latitudes pointed to by the end of the ſtem as it travelled up and down the ſaid plane in its retrograde revolution.

The little frame we have had occaſion to mention might do very well as a piece of mechaniſm for a radius vector, where the length is ſmall, but where the planet is repreſented as moving at a conſiderable diſtance from the ſun, the mechaniſm contained in *fig.* 3. of *Plate* IV. is better adapted, where A B is the radius vector proportional to the mean diſtance, and embracing faſt the upper extremity of the tube of the wheel with unequal teeth; C is a contrate wheel of any number of teeth made faſt to a ſurrounding tube that has no motion; the horizontal arbor D has two pinions of equal numbers, no matter what, one of which, E, is connected with the fixed wheel C, and the other, F, is connected with a ſecond contrate wheel G, which is every way like the wheel C, except that its poſition is inverted for the ſake of making its direction of motion retrograde; the lower pivot of wheel G reſts in a cock H, attached to the end of the radius vector, and its upper pivot aſcending above the ſame carries the ſhort arm that ſupports the ſtem of the planet; laſtly, I is the inclined plate with a ſcale of latitudes, on which the end of the ſtem reſts, and by which it is made to aſcend through one portion of its orbit, after which its own weight brings it gradually down again. The inclined plate is ſo placed that the nodes may fall at their reſpective diſtances from the aphelion point; and all the changes of place ariſing from the combined cauſes of varying diſtance, varying velocity, and inclination of the orbit, are duly repreſented.

A ſimilar combination of mechanical contrivances was afterwards, in the year 1802, adopted by Mr. Pearſon, when he contrived and ſuperintended the conſtruction of the large planetarium at the houſe of the Royal Inſtitution in Albemarle ſtreet, London; though the means are ſomewhat different. The plane of the inſtrument was deſired by Dr. Thomas Young, at that time the lecturer, to be vertical inſtead of horizontal, which afforded the means of making the ſhort arms, repreſenting the reſpective excentricities revolve backwards by a weight ſuſpended to each, inſtead of the wheel-work which we have deſcribed: the inequalities among the teeth of the tubed wheels in this inſtrument effect one half of the equation, and the retrograde revolutions of the little arms produce the other, and make all the planets revolve according to equated motion, while the ſtems round which the ſaid ſhort arms revolve are, agreeably to Dr. Young's ſuggeſtion, ſo bent, as to repreſent alſo the inclination of the orbits, and conſequent heliocentric latitudes, for eſtimating which the ecliptic plate is put exactly in the plane paſſing through the centre of the ſun, or coincident with the plane of the earth's orbit. The ſmall divided plates carried by the ends of the radii vectores indicate both the equations and heliocentric latitudes; which obſervations we make here, becauſe the conſtruction of the inſtrument has never yet been publicly explained, except perhaps partially in the lectures, and becauſe the uſes of the different parts, not being obvious by mere inſpection, are as yet but little underſtood. For a more particular deſcription of this inſtrument, ſee our article PLANETARIUM.

But we are not to take for granted, becauſe one half of the greateſt equation will be thus repreſented at the point of mean diſtance by a radius vector and ſhort arm, that are to each other as the mean diſtance to the excentricity, that therefore half the equation will be equally well repreſented in every other part of the orbit of a planet. Let us examine this matter more particularly, and bring it to the teſt of actual calculation. Let the line S H, *fig.* 5. of *Plate* III. be the radius vector of Mercury, and H A the ſhort arm repreſenting the excentricity, which are to each other very nearly as 5 to 1; then when the planet is at A, its greateſt diſtance from S, the ſun, it is obvious from what has been ſaid, that its angular velocity, as it reſpects S, muſt be ſlower than if it were at P, or any other part of the line S A; conceive now the point H, round which the little arm revolves, to move forwards ſo far that the planet may fall back by means of the arm to the point *a*; then if a line were drawn from S to *a*, the equation or angle at S would be ſubtended by *a b*, the ſine of the angle A H *a* to radius A H, which line conſequently is perpendicular to the radius vector at the point *b*; the diſtance *b* H is the coſine of the ſame angle, and we have $\overline{\mathrm{S\,H} + \mathrm{H}\,b)}$ for the baſe of a right-angled triangle, and *b a* for the perpendicular of the ſame, to determine the angle at S or ſemi-equation, which is one of the ſimple caſes in plane trigonometry, where the baſe is uſed as radius, and the perpendicular as tangent of the required angle. For example, the mean diſtance of Mercury, as given by La Lande, is 38710, and its excentricity 7955.4, the mean diſtance of the earth being 100000; then if, agreeably to this ratio, we take the ſmall arm repreſenting the excentricity at unity, the radius vector muſt be 4.86587; for as 7955.4 : 38710 :: 1 : 4.86587; let the point *a* now be taken equal to 30° from A, and from the tables of natural ſines we have *a b* = .5000000 and S H + H *b* = 4.86587 + .8660254 = 5.7318954, hence

As log. 57319 - Ar. co. - .2417014
Log. 5000 - - - - .6989700

Tang. of ½ equation 4° 59′ 7″ - .9406714

In the ſame manner one half of the equation, correſponding to any other point *c* in the quadrant A Q, may be found where H *d* is the coſine to be added to the radius vector, and *c d* the ſine which conſtitutes the ſubtenſe of the required angle at S. In the ſecond quadrant from Q to P the radius vector minus the coſine becomes the baſe of the triangle at any point *e* or *g*, but the ſines at thoſe points are the perpendiculars *e f* and *g h*, as in the laſt quadrant, ſo that the baſe of the triangles ſucceſſively taken is conſtantly ſhortening from the aphelion to the perihelion points of the orbit, whilſt the perpendiculars are increaſing in the firſt quadrant, and then decreaſing in an inverted order in the ſecond, which circumſtance makes the equation greater in a given quantity of mean motion near the perihelion than near the aphelion, as the Newtonian theory requires. That a due eſtimate may be had of the effect produced by this mechaniſm in every part of Mercury's orbit, we ſhall ſubjoin a ſmall table containing the data and reſult of correſponding calculations for every ten degrees of mean motion; and parallel to the ſemi-equations ſo obtained, we ſhall put a parallel column of half the equations taken from the beſt tables as publiſhed by La Lande, from which it will be ſeen that the errors, which at moſt are a ſmall portion of the whole equation, are in exceſs from the aphelion or 0° to 102° of mean anomaly, and in defect from 102° to about 258°, then from 258° to 360° or 0° again in exceſs, which deviations from the truth are agreeable to the deviations ariſing from the approximation called the "elliptic hypotheſis," which Buliald proved from four obſerved places of the planet Mars, as obſerved by Tycho Brahe, makes the computed places more *backward* than the true ones in the firſt and third quadrants of mean motion, and more *forward* in the ſecond and fourth.

TABLE.

180	386587	00000	180	0	0	0	0	0	0

In examining the preceding table it may be ſeen that the place of mean motion, or point where the equation is a maximum, falls, according to the mechaniſm, ſomewhere between 100° and 110°, which, in La Lande's tables, is at 105°; let us try where it will fall exactly by the mechanical repreſentation.

The point B, where the line S B is a tangent to the ſmall circle, is the place of the planet's greateſt equation, and this point will be found beyond the firſt quadrant, a quantity equal to the angle Q H B, or, which is the ſame thing, H S B, or greateſt ſemi-equation; for as S H Q and S B H are both right-angled, and have the angle at S common to both, the third angle, H Q S, is equal to the third angle B H S, and, conſequently, the ſupplemental angle Q H B is equal to the ſupplemental angle H S Q, or greateſt ſemi-equation. *Q. E. D.*

But the greateſt ſemi-equation by the mechaniſm when computed is 11° 51′ 34″, therefore the place of mean motion falls at 90° + 11° 51′ 34″, or at 101° 51′ 34″, which point is ſhort of 105° by a quantity upwards of 3°. This want of exact coincidence is, however, of little or no moment in the mechanical repreſentation of the orbit, becauſe the quantity of the greateſt equation is nearly ſtationary for many degrees both before and after the exact point of mean motion. The repreſentation will be ſtill more accurate where the orbits have leſs excentricity, than that of Mercury, which is the caſe with all the other planets, except two out of the four newly diſcovered ones, *viz.* Pallas and Juno.

As we have had frequent occaſion in this article to ſpeak of a wheel with unequal teeth, made for the purpoſe of effecting alternate accelerations and retardations of angular motion, and have alſo ſeen the theory explained by Mr. Huygens, it may be proper to ſay a few words here about the practical method of cutting ſuch a wheel. This operation may be done by three different methods; firſt, the divided circle of the plate, to be uſed with the engine, may have the diviſions laid down unequally by Huygens' mode of transferring equal diviſions from an excentric circle to a concentric one, as already explained; and then the teeth may be cut in the ordinary way from theſe unequal ſpaces, when punched or drilled into dividing holes; or, ſecondly, an equally divided circle of the engine plate may be uſed, and the increments and decrements, previouſly calculated, may be given at each tooth by the micrometer ſcrew of ſuch an engine as either Hindley's or Rehé's; or, thirdly, which is the readieſt method, the wheel to be cut may have a hole drilled in the excentric point, and be placed thereby on the arbor of the engine, till all the teeth are marked with ſlight notches by the cutter, adjuſted for diſtance at each cutting, and then the hole in the centre muſt be uſed for completing the teeth in their proper direction; for when the cutter is put into the notches ſucceſſively, it will cut the teeth towards the centre without any guidance of the index or alidade; and this method is practicable with any common engine without a micrometer ſcrew for taking and giving ſmall portions, as deductions from or additions to a mean tooth. For the wheels with unequal teeth in the large planetarium of the Royal Inſtitution, in Albemarle ſtreet, London, the firſt method was uſed by the maker, M'Culloch, under the direction of the contriver both of the machine itſelf, and of the method uſed of rendering the teeth of certain wheels gradually unequal round each ſeparate ſemicircle, agreeably to the planetary motions to be produced thereby in the planets themſelves; but in an accurate and elegant machine ſince made (by Fidler) for himſelf, the laſt method was uſed with ſucceſs for the large wheel that produces the ſun's, or rather earth's annual equation.

Another, and that a very recently contrived method of exhibiting the equations of all the planetary orbits at the ſame time, together with their variable diſtances, by very ſimple mechaniſm, has been adopted by Mr. Pearſon in the machine we have juſt mentioned, as made by Fidler, under his own direction; this method has the advantage of ſhewing alſo the mean motions, and is well calculated for illuſtrating the irregularities of motion on which the various phenomena of the heavenly bodies depend, as well as for ſhewing the exact times at which they occur, and the countries to which they will be viſible. For a deſcription of the machine itſelf we refer the reader to the articles PLANETARIUM and ORRERY, and ſatisfy ourſelves in this place with an account of the principle by means of which the equations of the centre are effected. *Fig.* 1. of *Plate* IV. of *Planetary Machines*, which is illuſtrative of the principle in queſtion, is derived from *fig.* 4. of *Plate* III. which has been explained, but has the addition of a third diminutive arm at the end of the longer arm placed at the extremity of the radius vector; we have ſeen that one arm, equal in length to the excentricity of the orbit to be repreſented, will, by its retrograde revolution, give the diſtances and one half of the equation, very nearly, in every part of the orbit, and we have ſeen that if the ſaid arm were made equal to twice the excentricity it would give the whole equation near enough, but would not give the diſtances truly; now the introduction of the additional arm is to make the apparent place of the planet fulfil both theſe conditions, which it does in a ſurprizing manner. Let S J, in *fig.* 2, be a radius vector, revolving equably round the point S, in *fig.* 1, in which caſe the extreme end J will deſcribe the concentric circle J K O L Q R T V; let J *a* be a ſhort arm equal in length to the excentricity once and a half taken, which arm is made to revolve in a backward direction by means of the faſt grooved circle *d*, of the catgut *e f*, and of the pulley *g* of the ſame diameter as *d*, which mechaniſm anſwers as well as that in *fig.* 3, before deſcribed, and is ſimpler: over the pulley *g* is fixed faſt to a ſtem, borne by the radius vector, round which the pulley turns, another grooved circular piece J, round which the gut *h i* goes, and embraces alſo a diminutive pulley *a* of half the ſize of J, ſo that whilſt the radius vector and arm J *a* go each once round in contrary directions, the third or little arm *a* A, which is equal in length to only one half the excentricity, goes twice round in the ſame direction, in which the radius vector moves, and thus carries a planet at its extremity round the point S, in which the ſun is placed, very nearly agreeably to the laws of planetary motion, with regard both to angular velocity and diſtance in every part of the orbit. To render the effect thus produced more intelligible, conceive two pins made faſt in the line J A, *fig.* 1, conſidered as one line equal to twice the excentricity of the orbit to the radius S J, and let one of them be at C, the middle of the line, and the other at A, the extremity; then if this line preſerves its paralleliſm all round the orbit, by a retrograde motion given to it by the catgut *e f* and pulley *g*, *fig.* 2, the pin C being at the diſtance of the excentricity S G from the end J of the radius vector, will deſcribe the excentric orbit 1, 2, 3, I, 4, 5, 6, of the planet, while the pin at A will have the proper velocity as ſeen from S, but will move in the circle A B D E P F M H, which is too excentric to become the true orbit; but if the point A of the additional ſmall arm be put to C when the motion begins, and has the planetary body placed on its extremity, then it will move in the ſame excentric circle as the firſt pin C, but with the apparent angular velocity of the ſecond pin A as ſeen from the other focus W, and very nearly ſo as ſeen from the ſun at S: for conceive the radius S J to have moved to K, the pin A will be found at B, on account of the angle B K *b* being equal to the angle J S K, which is here 45°, but the planet has moved a quadrant to 1, and is found in the circle deſcribed by the pin C, or middle circle; but, viewed from W, according to the elliptic hypotheſis, is ſeen in the line W B, as though it had been actually at B in the outermoſt circle; again, when the radius vector has completed a quadrant and is in the ſituation S O, the firſt pin is at N, the ſecond at D, and the planet at 2, in the line W D as before, and the additional arm has now deſcribed a ſemicircle: here the equation D S O is ſubtended by double the excentricity very nearly: when J is advanced 135° to L, the additional arm has moved $\frac{3}{4}$ of a circle, and is found at 3, ſtill in the middle circle, and alſo in the line W E, extended: and when S Q is the ſituation of the radius vector the planet is at I, the perihelion point of the middle circle, and alſo in the line W P, extended as before. In like manner in the other ſemicircle of mean anomaly, when the extreme end of the radius vector is ſucceſſively at the points R, T, and V, the planet will be found at the points 4, 5, and 6, and alſo in the lines W F, W M, and W H, reſpectively, ſtill moving in the middle circle, till it arrives at the aphelion point C, from which it originally ſet out. When the pulleys are made to produce this effect very nicely, the band or gut, that embraces two pulleys of different diameters, will effect the ratio of 1 : 2 in practice, and will require the ſmaller pulley to be ſomewhat leſs in diameter than what the exact proportion requires in theory. The radius vector has a ſlit in its remote end, with a thumb-ſcrew under it, to fix the pulley at a greater or leſs diſtance, as the tenſion of the gut may require, and the whole contrivance being ſimple, ſteady in its motion, and light in its conſtruction, as well as having a tendency to prevent the radius vector from bending downwards, is far preferable, in every point of view, to any contrivance we have before ſeen for anſwering the ſame purpoſe. The mechanical repreſentation of the orbit bears the ſame analogy to the elliptic hypotheſis, that an excentric circle does to an ellipſe of the ſame excentricity, and in the orbits of the planets theſe figures are ſo nearly alike, that they may be ſubſtituted for each other, without ſenſible error; and we may add, that the equation produced by only one arm, equal to twice the excentricity, is by no means ſo accurate as the *equation doubled*, that is, produced from an arm equal to the exact excentricity, becauſe the tangents of different angles do not increaſe by equal quantities.

Beſides the preceding methods of producing the equation of a planet's orbit, our author has contrived to indicate the quantity thereof in any point of the orbit, as well as the latitude alſo, as ſeen from the ſun; this is done by means of a hand fixed under the revolving pulley J, travelling over a divided and ſilvered plate, fixed faſt in the ſituation of the dotted circle, on the end of the radius vector, concentric with the pulley, which plate not only ſhews the equation and latitude at any time, but is of uſe in placing the arms in their proper ſituations by the latitudes taken from the Ephemeris or Nautical Almanac.

Theſe are all the methods that have fallen within our notice, of effecting the grand equation of a planet's orbit, as applied to an orrery, or planetarium; but there remain yet two pieces of mechaniſm, contrived by our preſent inventor, that are well calculated to explain in a lecture-room the equation of an individual planet, as detached from the ſyſtem, which we ſhall briefly deſcribe, as being contrivances equally novel and competent to their purpoſe. The firſt is repreſented by *figs.* 4 and 5 of our laſt plate, the former being a ſection of the wheel-work, and the latter a ſketch of a part of the viſible part of the inſtrument. AB is a little frame, containing four wheels, *a*, *b*, *c*, and *d*; *a* and *b* are equal in diameter, and of ſimilar numbers of teeth, *a* fixed on the arbor of the handle *e*, and *b* on a tubed arbor *f*, that carries the index *g*, ſeen in *fig.* 5 of the ſhape of a T, with a point touching the circle *k*, which is an ecliptic circle; ſo that whatever velocity is given by the handle to the wheel *a* in an equable manner, the ſame is communicated, by the medium of the wheel *b*, to the index *g*, which therefore moves according to mean motion in the ecliptic circle K. The wheels *c* and *d* are excentric, and have alſo ſimilar diameters and numbers of teeth, but are placed to act ſo, that the longeſt radius of one always acts with the ſhorteſt of the other, and thus produce the ſame effect as Dr. Deſaguliers' elliptic grooved plates with the endleſs catgut. The excentricity of the wheels bears the ſame proportion to their common radius, that the excentricity of the planet's orbit does to its mean diſtance: wheel *c* is fixed faſt to the ſame arbor of the handle as wheel *a* is, but wheel *d* has a ſeparate arbor, which goes with the tube of wheel *b*, and carries the hand *i*, and on its upper end a ball to repreſent the ſun. The ſectoral arc of the index *g* is graduated, for Mercury for inſtance, into 24° each way from the middle, to which the hand *i* muſt be put when the index points to that part of the ecliptic circle in which the aphelion point of the planet is; then as the handle is turned the index ſhews the mean motion in the ecliptic, which may have a ſecond circle divided into ſigns of mean anomaly, beginning at the aphelion point, and as the motion proceeds the hand *i* falls back, till at the end of three ſigns and a half of mean anomaly it is found near the extremity of the ſectoral arc, at *g*; at the perihelion point the hand is again in the middle; and at eight and a half ſigns of mean anomaly it will be in its preſent ſituation again, at its greateſt equation, at the oppoſite end of the ſectoral piece; and laſtly, at the aphelion point the hand will be again found in the middle, which is the zero of both the poſitive and negative equations, which are reſpectively marked + and − on the oppoſite ends of the graduated ſectoral arc. Thus, the index *g* ſhews the mean motion, the hand *i* the equated motion, and the graduated portion of the index has the quantity of the equation plus or minus, ſhewn by the hand *i* in every part of the orbit, while a line drawn from S, the ſun, over the point of the hand *i* to the ecliptic K, ſhews the equated or true heliocentric place of the planet. The other inſtrument for explaining the nature of the mean and equated anomaly of a detached planet, and of its equation, which is their difference, is ſimply a mechanical conſtruction of the elliptic hypotheſis of biſhop Ward, and is repreſented by *fig.* 6. of the ſame plate. S G W is an elliptic plate of wood or metal, deſcribed from the foci S and W, the ſmall circle at S is divided into an ecliptic circle with a ſlender ſtem in the centre bearing a ball to repreſent the ſun, and the other ſimilar circle at W is divided into as many ſpaces as there are days or weeks in the period of the planet; of which 88^d are proper for Mercury; the bar *a* G is concealed under the dotted line, and turns on the vertical ſtem of the ſtand that ſupports the elliptical plate at G, by means of a piece of braſs tube fixed at its end; on the bar *a* a ſliding piece *b* is inſerted, that bears a ſmall pulley *c*, and a planet in the angular point behind it, on a ſtem as high as that of the ſun; this ſliding piece has two rollers, bearing againſt the edge of the elliptical plate, to facilitate the motion of the bar round the plate, which is produced by hand; an endleſs gut or ſilk cord S W *c* draws the ſliding piece cloſe to the ſaid plate, and cauſes the pulley and planet to deſcribe the proper ellipſe for the orbit. According to the elliptic hypotheſis, if the angle *c* W A be the meaſure of the mean anomaly, the angle at the ſun in the other focus, *viz.c* S A, will always be the equated anomaly, and the ſmall angle S *c* W will, in every ſituation, be the equation of the centre, as being the ſupplement of the ſum of the other two angles, that is, the external angle *c* W A, that repreſents the mean anomaly, is equal to the ſum of both the internal angles of the triangle at S and *c*, as being reſpectively the ſupplement of the other internal angle at W; but the internal angle at S is the equated anomaly; therefore the angle *c* W A − ∠*c* S W is the angle *c*, or equation during the firſt ſix ſigns of mean anomaly; in the other ſix ſigns the angle repreſenting the mean anomaly at W will be ſmaller than the angle at S, repreſenting equated anomaly, therefore the equation, or difference between them, which has been ſubtractive, becomes now additive; and the hypotheſis, thus mechanically conſtructed, affords the ready means of explaining the particulars of planetary motion, for which purpoſe equal ſectoral arcs are laid down on the plate alternately black and white, which the thread S *c* moves over in equal arcs of the circle W, moved over by the thread W *c*; which are equal portions of time; and when the circle W is divided into days or weeks, and the circle S into ſigns of longitude, and alſo into ſigns of anomaly, the ſame reſults will follow as from the preceding mechaniſm, as nearly as may be, while, at the ſame time, all the variations of diſtance, as well as of the equation, will be faithfully exhibited. Both theſe contrivances may be conſtructed ſo as to be uſed either horizontally or vertically, and on any ſcale of magnitude that the audience of a lecture room may require.

Equation *of Time.* Having, under the article Day, explained the origin of the difference between ſolar and mean time, we have now only to explain the method by which this difference is calculated.

To effect this, it is neceſſary to know preciſely the motion of the ſun, and the dimenſions of its orbit: we may then calculate the arc which it deſcribes every day in the year parallel to the equator. If this real and variable motion be compared with its mean motion, the difference will be the equation of time.

If we imagine two meridians, drawn through the two extremities of the arc of the ecliptic, which the ſun deſcribes in one day, the arc of the equator, which they intercept, is the difference between the ſolar and a ſidereal day; for when the rotation of the celeſtial ſphere is terminated, this ſmall arc of the equator muſt traverſe the meridian before the centre of the ſun can arrive there. Now as this arc is not always of the ſame length, the ſolar days are not all equal.

Nor would they be ſo, even if the ſun deſcribed every day an equal arc of the ecliptic, for theſe arcs take ſucceſſively different inclinations relatively to the equator. At the moment of the equinoxes, they cut this plane at an angle equal to the obliquity of the ecliptic, and at the period of the ſolſtices they are parallel to it. The meridians drawn through the extremities of theſe diurnal arcs are more ſeparated at the ſolſtices than if they contained the ſame arc at the time of the equinoxes; and, as it is this ſeparation of the two meridians which meaſures the ſucceſſive retardations of the ſun, theſe are unequal, and leſs at the equinoxes than at the ſolſtices. The daily variation of the motion of the ſun in its orbit is another ſource of inequality, as it augments and diminiſhes the diurnal arc of the ecliptic, and this produces a correſponding variation in the arcs of the equator contained between the above-mentioned meridians.

Thus the inequality in the ſolar days ariſes from two diſtinct cauſes, the obliquity of the ecliptic, and the unequal motion of the ſun in its orbit. As theſe two cauſes each produce their ſeparate effect, they muſt be both deſtroyed, to render the ſolar days equal, that is, the motion of the ſun muſt become uniform, and the ecliptic muſt coincide with the equator.

To calculate the value of the equation of time, we muſt calculate the arc which the ſun deſcribes each day on the ecliptic, and project it on the equator, and from this deduct the mean diurnal motion: the difference will give the equation of time for that day.

To repreſent theſe reſults geometrically, we may ſuppoſe an artificial ſun to move in the manner deſcribed under the article Day, the mean day is the interval between two ſucceſſive returns of this fictitious ſun, and the mean noon the inſtant of its paſſage over the meridian; and the mean equinox is the inſtant of its paſſage through the equinoctial point. It is obtained by a ſimple proportion, when the longitude of the perigee is known, and the epoch when the true ſun is in the apſides, the time which elapſes between two conſecutive returns to the mean equinox, forms the mean tropical year, and which is equal to 365,^{d} 242250.

To calculate the place of the mean ſun on the equator for a given inſtant, it is ſufficient to calculate the mean longitude, and this, reduced to the equator, is the mean right aſcenſion of the ſun.

The projection of the true ſun on the equator may either be determined from obſervation, or from calculating its right aſcenſion. The difference between their right aſcenſions, reduced into time, in the proportion of 24^h to 360°, indicates the interval between the paſſage of the true and mean ſun, and is the required equation of time: it is ſometimes additive, and ſometimes ſubtractive, and has the remarkable property of becoming zero four times in a year.

To underſtand the reaſon of this phenomenon, let us imagine (*fig.* 108.) two ſuns, S^2 and S^4, to ſet out at the ſame time from the equinox, both moving with an uniform motion; the one, S^2, in the ecliptic, the other, S^4, in the equator, and let the motion of each be referred to the latter plane. S^3 will at firſt advance upon the meridian of S^3, but afterwards this latter will approach it, and they will arrive together at the ſolſtice; after this the meridian of S^2 will advance upon that of S^3, till the ſecond equinox, where they will arrive together. The ſame circumſtances will occur in the other half of the orbit, and thus the two ſuns will coincide together four times in the year, namely, at the equinoxes and ſolſtices.

But, in reality, the mean ſun does not ſet out at the ſame time as the true ſun; they will not, therefore, meet at the ſame points; the unequal motion of the ſun changes this difference, but theſe two cauſes united only change the epoch of the coincidences; their number remains the ſame.

Let us conſider the motion of the two ſuns, S^2, and S^3, ſuppoſed to ſet out together from the autumnal equinox, and proceeding towards the perigee. The true ſun, S^1, which deſcribes the ecliptic, being referred by its meridian to the plane of the equator, will then be found behind the others, for it is preceded by S^2 till the perigee; let us now conſider the motion of the other two. Till the moment of the ſolſtice, S^3 precedes S^1, and S^2 precedes S^1, their order is therefore S^1, S^2, S^3. At the ſolſtice S^3 joins S^1, and afterwards paſſes it; their order is then S^2, S^3, S^1, but at the perigee S^1 coincides with S^2, and afterwards precedes it: to do this S^1 and S^3 muſt meet in the interval. The order then becomes S^1, S^3,

S^2, S^1; thus between the winter ſolſtice and the perigee the true ſun S^1, referred to the equator, meets the mean ſun S^3, and the equation becomes zero. From the perigee to the vernal equinox S^1 precedes S^2, and S^2 precedes S^3; they none of them meet therefore in this interval. At the equinox S^3 joins S^2, and their order becomes S^2, S^3, S^1; but S^3 cannot remain long between the two others, for at every quadrant the ſeparation of S^3 and S^2 increaſes to 2° 24′ 24.″4, as appears by calculation; but the diſtance of S^1, S^2 never exceeds 1° 55′ 27″, which is the greateſt equation of the centre, and as, in the preſent ſituation of the ſolar orbit, this takes place near the equinoxes, the arc which correſponds to it on the equator is ſtill leſs than it. It is evident, therefore, after the vernal equinox, and before the ſummer ſolſtice, there muſt be ſome moment when the mean ſun S^3 arrives upon the meridian of S^1, when the equation is again zero. From that point to the ſummer ſolſtice the order is as follows, S^2, S^1, S^3: at the ſolſtice S^2 joins S^3, and afterwards paſſes it. But S^1 precedes S^2 as far as the apogee, conſequently the meridian of S^1 joins the mean ſun S^3, before the ſolſtice, and the equation becomes zero for the third time.

From the ſolſtice to the apogee, the order of the three ſuns is as follows, S^3, S^2, S^1; at the apogee S^2 joins S^1, and afterwards precedes it till the perigee, the order thus becoming S^3, S^1, S^2; but at the autumnal equinox S^3 joins S^2, and conſequently meets in this interval the meridian of S^1, and the equation becomes zero for the fourth time.

The order of the three ſuns then becomes S^1, S^2, S^3, and the ſame appearances are re-produced in the ſame order as before.

Hence it appears, that in conſequence of the obliquity of the ecliptic, combined with the unequal motion of the ſun, the equation of time becomes zero four times a year, *viz.* once between the winter ſolſtice and the perigee, twice between the vernal equinox and the ſummer ſolſtice, and for the laſt time between the apogee and the autumnal equinox. The epochs of theſe phenomena evidently vary with the poſition of the greater axis of the ſolar orbit; at preſent they happen about the 24th December, 15th April, 15th June, and the 31ſt of Auguſt. If the equator coincided with the ecliptic, that part of the equation of time depending on their inclination would diſappear, and the mean motion would only differ from the true by the equation of the centre, and mean and true time would agree twice a year when the ſun is in the apſides.

Dr. Maſkelyne has invented a rule for computing the equation of time, in which all the three cauſes are conſidered; it was inveſtigated in the following manner.

Let A P L Q (*Plate* XII. *fig.* 109.) be the ecliptic, A L Q the equator, A the firſt point of Aries, P the point where the ſun's apparent motion is ſloweſt, S any place of the ſun; draw $S v$ perpendicular to the equator, and take $A n = A P$. When the ſun begins to move from P, ſuppoſe a ſtar to begin to move from n, with the ſun's mean motion in right aſcenſion or longitude, *viz.* at the rate of 59′ 8″ in a day; and when n paſſes the meridian, let the clock be adjuſted to 12; take $n m = P s$, and when the ſtar comes to m, if the ſun moved uniformly with his mean motion he would be found at s, but at that time let S be the place of the ſun. Let the ſun S, and conſequently v, be on the meridian; and then as m is the place of the imaginary ſtar at that inſtant, $m v$ muſt be the equation of time. The ſun's mean place is at S, and as $A n = A P$, and $n m = P s$, we have $A m = A P s$; conſequently $m v = A v - A m = A v - A P s$. Let A be the mean equinox, or the point where it would have been if it had moved with its mean velocity, and draw $A z$ perpendicular to $A Q$: then $A m = A z + x m = A a \times$ coſine $z A a + z m$: or becauſe the coſine of $z A a$, the obliquity of the ecliptic 23° 28″ $= \frac{11}{12}$ very nearly, $A m = \frac{11}{12} A a + x m$: hence $m v = A v - z m - \frac{11}{12} A a$. Here $A v$ is the ſun's true right aſcenſion; $z m$ the mean right aſcenſion, or mean longitude; and $\frac{11}{12} A a$ (*viz.* $A x$) is the equation of the equinoxes in right aſcenſion; therefore the equation of time is equal to "the difference of the ſun's true right aſcenſion, and his mean longitude corrected by the equation of the equinoxes in right aſcenſion."

When $A m$ is leſs than $A v$, mean or true time precedes apparent; when it is greater, apparent time precedes mean: that is, when the ſun's true right aſcenſion is greater than his mean longitude, corrected as above ſhewn, we muſt add the equation of time to the apparent to obtain the mean time; and when it is leſs we muſt ſubtract. To convert mean time into apparent, we muſt ſubtract in the former caſe, and add in the latter.

Tables of the equation of time are computed by this rule for the uſe of aſtronomers; they are either calculated for the noon of each day, as given in the Nautical and ſome other Almanacs, or for every degree of the ſun's place in the ecliptic, as is done in the annexed tables.

Strahan and Preſton,
New-ſtreet Square, London.

Equation, *lunar* and *ſolar*, in *Chronology*. See Metempsychosis.

EQUATOR, or Æquator, in *Aſtronomy* and *Geography*, a great circle of the ſphere, equally diſtant from the two poles of the world, or having the ſame poles with thoſe of the world.

Such is the circle D A (*Plate* XII. *Aſtron. fig.* 109.) its poles being P and Q. It is called the equator, becauſe when the ſun is in it the days and nights are equal; whence alſo it is called the *equinoctial;* and when drawn on maps and planiſpheres, the *equinoctial line*, or ſimply the *line*. Every point of the equator is a quadrant's diſtance from the poles of the world; whence it follows, that the equator divides the ſphere into two hemiſpheres, in one of which is the northern, and in the other the ſouthern pole.

By the paſſages or tranſits of arcs of the equator over the meridian, equal or mean time is eſtimated; hence we have frequent occaſion for the converſion of degrees of the equator into time; and again, for the re-converſion of parts of time into degrees or parts of the equator.

For the performance whereof, we ſubjoin the following table; wherein are exhibited the arcs of the equator, which paſs the meridian in the ſeveral hours, minutes, &c. of equated or mean time.

Converſion of the Parts of the Equator into Time, and *vice verſâ.*

Deg. of Equat.	Hours.	Min.	Hours.	Deg. of Equat.	Hour. Min.	Deg. of Equat.	'
Min.	Min.	Sec.	Min. '	Min. '	Sec.	Min. '	"
Sec.	Sec.	Third	Sec. "	Sec. "	Third.	Sec. "	‴
Third.	Third.	Fourth.	Th. ‴	Th. "	Fourth.	Th. ‴	‴
1	0	4	1	15	1	0	15
2	0	8	2	30	2	0	3
3	0	12	3	45	3	0	45
4	0	16	4	60	4	1	0
5	0	20	5	75	5	1	15
10	0	40	6	90	6	1	30
15	1	0	9	135	10	2	30
30	2	0	12	180	20	5	0
60	4	0	15	225	30	7	30
90	6	0	18	270	40	10	0
180	12	0	21	315	50	12	30
360	24	0	24	360	60	15	0

The conſtruction of this table is very eaſy; for the equator being divided into 360 degrees, and revolving always in 24 hours, any point of it moves through 15° in one hour, and in one minute through the 60th part of 15°, or 15′ of a degree, and in one ſecond through 15″ of a degree, &c. and therefore nothing more is neceſſary beſides ſimple addition, in order to have the number of degrees, minutes, and ſeconds, which it deſcribes in any given time.

The uſe of the table is obvious; ſuppoſe, *e. gr.* it were required to turn 19° 13′ 7″ of the equator into time: againſt 15 deg. in the firſt column we have 1^h 0′ 00″; againſt 4 deg. we have 16′ 0″; againſt 10 minutes, 40″; againſt 3 minutes, 12″ 0″; againſt 5 ſeconds, we have 0′ 20‴; and againſt 2 ſeconds, 8″; which, added together, give 1^h 16′ 52″ 28‴.

Again, ſuppoſe it were required to find how many degrees, minutes, &c. of the equator anſwer to 23 hours 25 min. 17 ſec. and 9 thirds. Againſt 21^h in the fourth column of the table, you have 315; and againſt 2 hours, 30; againſt 20′, 5°; againſt 5′, 1° 15′; againſt 10 ſec. 2′ 30″; againſt 5 ſec. 1′ 15″ 0‴; againſt 2 ſec. 30″ 0‴; againſt 6 thirds, 1″ 30‴; and againſt 3 thirds, 45‴; which, added together, give 351° 19′ 17″ 15‴. See Equinoctial.

Equator, *elevation* or *altitude of the*. See Elevation *of the equator*.

Equator *of the Sun*, or *Solar Equator*. The ſun revolves from eaſt to weſt on an axis inclined to the ecliptic, and the plane, paſſing through the centre of the ſun perpendicular to this axis, is called the plane of the ſun's equator. It cuts the plane of the ecliptic in a ſtraight line, called the line of the nodes of this equator; and the nodes themſelves are the points where this line, produced each way, meets the celeſtial ſphere.

To determine the poſition of the axis of rotation in ſpace, it is neceſſary to determine the inclination of the ſolar equator to the ecliptic, and the angle which the line of nodes makes with ſome fixed line in the plane of the ecliptic, for example, with the line of the equinoxes. This angle is called the longitude of the nodes of the ſolar equator, and is thus determined: when the poſition of a ſpot on the diſc of the ſun has been obſerved, and its latitude and longitude determined, the direction of the viſual rays drawn to the ſpot at the moment of obſervation is known. The longitude of the ſun at the ſame inſtant is likewiſe known, its diſtance from the earth, and its apparent diameter.

The interſection, therefore, of its ſurface with this ray, is found by a ſimple geometrical proceſs. Three ſimilar obſervations of the ſame ſpot determine three points upon the ſurface of the ſun, and theſe three ſpots are ſituated on the ſame circumference of ſome circle parallel to the ſolar equator, and the poſition of a plane is known when it paſſes through three given points. The plane of this circle deſcribed by the ſpot will, therefore, be known by theſe obſervations, by which the poſition of the ſolar equator may be determined.

To determine the ſucceſſive poſitions of the ſpots on the ſurface of the ſun, ſuppoſed ſpherical, we may imagine the three rectangular co-ordinates or axes paſſing through the centre of the ſun, and continuing parallel to each other during the whole annual revolution. The firſt of theſe axes is perpendicular to the ecliptic, the two others are ſituated in this plane, one parallel to the line of the equinoxes, the other perpendicular to it. Latitudes and longitudes, reckoned relative to theſe axes from the centre of the ſun, are called heliocentric, and they may evidently be found by trigonometric methods, if we can determine their analogous longitudes and latitudes meaſured in the ſame manner from the centre of the earth, and which are called geocentric.

By methods of this kind it has been found that the ſolar equator is inclined to the ecliptic about 7°. It continues conſtantly parallel to itſelf, the points of this equator, as they are raiſed by the rotatory motion of the ſun above the plane of the ecliptic, traverſe this plane in a point which, ſeen from the centre of the ſun, was, in 1750, 85°. This was then the heliocentric longitude of the ſolar equator. Since that time it has undergone no variation except what ariſes from the motion of the equinoctial points.

EQUATORIAL Instrument, is an inſtrument made uſe of in *Practical Aſtronomy*. When a ſimple teleſcope, mounted on a ſtand, is elevated to view any heavenly body at the moment of its meridian paſſage, the obſerved body appears to paſs horizontally acroſs the field of view, but in any other ſituation to the eaſt or weſt of the meridian, the apparent paſſage of any heavenly body through the field of view, is in an oblique direction, and the more ſo, the greater the declination towards the viſible pole, and alſo the greater the diſtance from the meridian line. Hence the motion of the ſimple teleſcope, which moves in a parallel of altitude, or circle parallel to the horizon, when turned round in a ſtate of elevation on its vertical axis, will never coincide with the motion of a heavenly body, that moves either in the equator, or in a circle parallel to it; unleſs indeed the obſerver could ſtand at one of the poles, in which caſe the equator would become the horizon, and circles of altitude would be alſo circles of declination. But no obſerver can be ſo circumſtanced. He may, however, incline the axis of motion of his teleſcope, ſo as to be placed in the meridian, and exactly parallel to the earth's axis, and then, when the field of view is directed to take in any heavenly body, the motion of ſuch inclined axis, or the motion of the teleſcope round ſuch axis, ſuppoſing the axis to be fixed, will attend the ſaid body during the remainder of its path above the horizon. Accordingly we find Chriſtopher Scheiner uſing a teleſcope mounted on a polar axis in the year 1620, which time was ſoon after Galileo had invented the ſimple dioptric teleſcope, and though John Muller, or Regiomontanus, had contrived and deſcribed his torquet, a kind of portable equatorial, in the year 1544, and alſo Tycho Brahe had given the name of *equatoriæ* to ſome of his inſtruments about thirty years afterwards, yet the idea of Scheiner's polar axis no doubt ſuggeſted to the modern inſtrument-makers the beſt principle on which an equatorial inſtrument, as well as equatorial ſector, and equatorial ſtands, ought to be conſtructed. Scheiner's contrivance was competent to the following of a ſtar or other heavenly body through its diurnal arc, but had no appendages by which to aſcertain the place of the obſerved body, as to right aſcenſion, declination, diſtance from the meridian, &c. neither would the teleſcope be directed to a body inviſible to the naked eye for want of ſuch appendages.

Mr. Henry Hindley, an eminent clock-maker at York, was probably the firſt man who contrived and attached the different adjuſtable circles as companions to the teleſcope. Mr. Smeaton, in his paper on the "Graduation of Aſtronomical Inſtruments," read before the Royal Society of London, on November 17, 1785, has informed us, that Hindley contrived an inſtrument of the equatorial kind ſo early as the year 1741, which was ſent up to London to be ſold in the year 1748. This inſtrument had the equatorial plate, quadrant of latitude, and declination ſemi-circle indented at the circumference, and moved by worm-ſcrews, containing fifteen threads each, all in action together, which ſcrews at the ſame time meaſured as micrometer ſcrews, the angular motions, and, as it ſeems, without other graduations. The teleſcope was of the refracting kind, and inverted the object viewed. "It ſtaid with me," ſays Mr. Smeaton, "two years, in which time I ſhewed it to all my mechanical and philoſophical friends, amongſt whom was Mr. Short, who afterwards publiſhed, in the Philoſophical Tranſactions, an account of a portable obſervatory, but without claiming any particular merit from the contrivance. However, the model of it differs from Hindley's equatorial only in the following articles: he added an azimuth circle and compaſs at the bottom; he omitted the endleſs ſcrews, placing verniers in their ſtead, and at the top a reflecting teleſcope inſtead of a refractor. This inſtrument of Hindley's being afterwards returned to him unſold, I pointed out the principal deficiencies that I found therein; *viz.* that in putting the inſtrument into different poſitions, the ſpringing of the materials was ſuch, as in ſome poſitions to amount to conſiderable errors. This remained with him in the ſame ſtate till the year of the firſt tranſit of Venus in 1761, when it was ſold to —— Conſtable, eſq. of Burton Conſtable in Holderneſs. Mr. Hindley, to remedy the evil above-mentioned, applied balances to the different movements. He ſoon after completed one, *de novo*, upon this improved plan, for his Grace the late duke of Norfolk." The next, in point of time, to Mr. Hindley, was Mr. Short, who placed his reflecting teleſcope over a ſyſtem of graduated circles, and who has generally been conſidered as the firſt contriver of the equatorial inſtrument, though it appears evident from Mr. Smeaton's account, that Hindley's inſtrument was prior to his. Mr. Short publiſhed his account in the Tranſactions of the Royal Society, not in the year 1789, as ſtated by a typographical error under our article CIRCLE, but in 1749, in vol. xlvi. N° 493. About the year 1770 a rage for making equatorial inſtruments generally prevailed, and numberleſs were the modifications that makers of every deſcription produced, but the chief improvers of the inſtrument at that period were Nairne, Ramſden, and Dollond, who married Ramſden's ſiſter, all of whom, ſoon after the year juſt ſpecified, improved on the original portable inſtrument, chiefly by introducing the improved dioptric in place of the heavy catoptric teleſcopes, and by uſing the beſt divided circles, together with the moſt accurate adjuſtments, balancing of the parts, and nicely divided verniers. Mr. Ramſden, to ſecure the advantages of his ſhare of the improvements, took out a patent for his inſtrument, including the refraction apparatus, and hanging level in the year 1775.

Still, however, the equatorial inſtrument had its ſcale of magnitude adapted only for portability, and its circles conſequently were not capable of meaſuring with that degree of accuracy that celeſtial obſervations demand, to be of real uſe in the preſent improved ſtate of aſtronomy; and it remained for Mr. Edward Troughton to conſtruct an equatorial inſtrument ſufficiently large to be placed in an obſervatory, for the purpoſe of making uſeful obſervations. This ingenious artiſt contrived many commodious modifications of the inſtrument under our preſent conſideration, but we mean to confine our notice to two of the principal of them, both worthy of future imitation; one as a moveable, though not very portable inſtrument, and the other as a fixed one. The firſt was made to go to Coimbra, in Portugal, where it has had the ill fate to be ſhut up in the dark, though it was finiſhed ſo long ago as the year 1788; the latter is now in uſe under the direction of Dr. Hamilton, at Armagh, in Ireland, and is that with which the Armagh obſervations were made; of theſe Mr. Pond, the lecturer on aſtronomy at the Royal Inſtitution, availed himſelf when he compoſed his famous catalogue of declinations of ſome of the principal ſtars, which we noticed under our article CIRCLE, and which is inſerted in the article DECLINATION. This inſtrument was made in the year 1796; about three years after ſir George Shuckburgh's large equatorial inſtrument was deſcribed in the Philoſophical Tranſactions of London, as an inſtrument on a large ſcale, carefully made under Mr. Ramſden's direction by Mr. Berge, who has ſince become his ſucceſſor. The principal modern authors who have deſcribed the different equatorial inſtruments, are Mr. Short, Mr. Benjamin Martin, Mr. Nairne, Mr. Dollond, the Hon. Stuart M'Kenzie, profeſſor Vince, and ſir George Shuckburgh; at one time it was our intention to deſcribe one or two only of the different conſtructions of this inſtrument, and to have noticed the differences of the others; but to do juſtice to the ſubject, and to ſhow more clearly the progreſſive improvements in the art of conſtructing aſtronomical inſtruments of this deſcription, we have determined to give drawings and correſponding deſcriptions, in ſucceſſion, of each inſtrument that appears to poſſeſs any claim to originality. Of courſe we muſt avail ourſelves of the reſpective deſcriptions that have been publiſhed of the various inſtruments that have been before deſcribed, but our detail will be a condenſed one, and interſperſed with original remarks, tending to aſſiſt the reader in forming his opinion of their reſpective merits; and where no deſcription has been previouſly given, as is the caſe with Mr. Troughton's inſtruments, and a neat portable one by his nephew, Mr. Farer, we ſhall ſupply the accounts from original and authentic ſources, preſerving, as we proceed, that order of time in which the ſeveral inſtruments were conſtructed, except in the inſtance of Mr. Farer's, which being portable, we have thought it better to place immediately after the portable ones of older date, by way of contraſt, than to give it a place after the larger and more complete inſtruments.

Portable Equatorial Inſtrument by Mr. James Short.—We have already ſaid that Mr. Short's equatorial inſtrument, called by him the equatorial teleſcope, or portable obſervatory, was the firſt inſtrument probably made in England that could be conſidered as a well arranged aſſemblage of graduated circles for aſcertaining the various data of a heavenly body's place, out of the meridian, by a ſingle obſervation. Mr. Ben. Martin has given a brief deſcription of this inſtrument, together with its uſes, in appendix II. of his Philoſophia Brittannica, the ſubſtance of which, not being in every one's hands, we think may be acceptable to our readers, particularly as its peruſal will afford the beſt means of contraſting the more improved inſtruments with the original model, and, conſequently, of tracing the progreſs that the art of making inſtruments of this kind has made within the period of our own recollection. *Fig.* 1. of *Plate* XI. of *Aſtronomical Inſtruments*, exhibits a perſpective view of all the eſſential parts of Mr. Short's inſtrument, which is compoſed of four graduated circles, two of them entire, and two of them about three-fourths of a circle, together with a four-footed ſtand, a variety of ſupporting pillars, levels, wheels, and endleſs ſcrews, axes of motion, and a reflecting teleſcope ſurmounted over the whole. A, A, are two horizontal plates one over the other, and repreſenting the horizon of the place of obſervation; theſe plates reſt on four pillars of the pedeſtal, that contains a magnetic box and needle, and that is ſupported by the four adjuſtment ſcrews B, B, B, B, the lower plate being faſt to the pillars, and the upper one, that carries two ſpirit levels on its plane at right angles to each other, being moveable by a rod or handle C, the ſcrew on which takes into the teeth cut on the edge of this upper horizontal plate. This moveable plate is divided into 360°, and a vernier borne by the under plate reads to the accuracy of every *three minutes*. Another ſet of four pillars, inſerted into the moveable horizontal plate, ſupports the vertical circle D D, or rather portion of a circle, which is divided into twice 90°, and ſomewhat more at each ſide, and is called the meridian circle; its vernier, placed on the upper horizontal circle, reads alſo every three minutes of ſpace. The handle or rod E moves this circle in like manner as the rod C moves the horizontal circle deſcribed. On the upper or mutilated part of the meridian circle D D, are placed two other plates, the upper one moveable on the under one, like the horizontal plates, and the vernier carried by the under one. It does not appear from the drawing or account whether the axis of motion rotates or is fixed. The upper or moveable plate, marked F F, is divided into hours and ten-minute ſpaces, and theſe again are ſubdivided by the vernier into ſingle minutes of time. This plate, which is called the equatorial plate, has a third ſet of pillars inſerted into it, and is moveable by the rod G, like the other moveable plates; the pillars ſupport a fourth circle, or rather mutilated circle H H, on the upper part of which the teleſcope L L is mounted, as ſeen in the drawing. This uppermoſt circle is called the circle of declination or horary circle, and is divided into twice 90°; it is alſo moveable by the rod or handle K, like the reſt of the moveable circles; and has every three minutes of ſpace, by its vernier, placed on the plane of the equatorial circle. The teleſcope is of the Gregorian conſtruction, with a great ſpeculum of 18 inches focal length. In making the adjuſtments of this inſtrument for obſervation, the horizontal plates A, A, are firſt levelled by the joint aid of the two levels and ſcrews of adjuſtment that bear the whole fabrick; this adjuſtment is not perfect till the bubbles of the levels will remain ſtationary, in the middle of their tube, while the upper plate is carried quite round the ſubjacent one. In the next place the meridian circle D D is turned by its handle E, till the equatorial plates are parallel to the equator; that is, till they are raiſed equal to the complement of the latitude of the place of obſervation, and the inſtrument is ſaid to be fit for making obſervations; of courſe the placing of the circles relatively to each other, in regard to perpendicularity, and of the line of collimation of the teleſcope in regard to the points zero in the declination circle, are ſuppoſed to be immoveably adjuſted by the maker, ſo as to require no future rectification. As it will be of ſome importance to the developement of the progreſſive improvements of the different equatorial inſtruments, to confine ourſelves to the uſes that this inſtrument by Mr. Short was applied to, we cannot do better than confine ourſelves to the words of one of the early deſcriptions of its practical application.

"*To find the Hour of the Day, and Meridian of the Place;*—Firſt, find, from aſtronomical tables, the ſun's declination for the day, and for that particular time of the day; then ſet the declination-ſemicircle to the declination of the ſun, taking particular notice whether it is north or ſouth, and ſet the declination-ſemicircle accordingly.

"You then turn about the horizontal handle, and the equatorial handle, both at the ſame time, till you find the ſun preciſely concentrical with the field of the teleſcope. If you have a clock or watch at hand, mark the inſtant of time; and by looking upon the equatorial plate and vernier, you will find the hour and minute of the day, which comparing with the time ſhewn by the clock or watch, ſhews how much either of them differs from the ſun. In this manner you find the hour of the day.

"Now, in order to find the meridian of the place, and, conſequently, to have a mark by which you may always know your meridian again, you firſt move the equatorial plate, by means of the equatorial handle, till the meridian of the plate or hour-line of 12 is in the middle of the vernier; and then, by turning about the declination-handle till the teleſcope comes down to the horizon, you obſerve the place or point which is then in the middle of the field of the teleſcope; and a ſuppoſed line, drawn from the centre of this field to that point in the horizon, is your meridian line. The beſt time of the day for making this obſervation for finding your meridian is about three hours before noon, or as much after noon. The meridian of the place may be found by this method ſo exact, that it will not differ at any time from the true meridian above 10″ of time, and if a proper allowance be made for the refraction at the time of obſervation, it may be found much more exact. This line thus found will be of uſe to ſave trouble afterwards; and is, indeed, the foundation of all aſtronomical obſervations.

"*To find a Star or Planet in the Day-Time, even at Noon-Day.*—The inſtrument remaining as rectified in the laſt experiment, you ſet the declination-ſemicircle to the declination of the ſtar or planet you want to ſee; and then you ſet the equatorial plate to the right aſcenſion of the ſtar or planet at that time, and, looking through the teleſcope, you will ſee the ſtar or planet; and after you have once got it into the field, you cannot loſe it: for, as the diurnal motion of a ſtar is parallel to the equator, by your moving the equatorial handle ſo as to follow it, you will at any time, while it is above the horizon, recover it, if it be gone out of the field.

"The eaſieſt method for ſeeing a ſtar or planet in the day-time is this; your inſtrument being adjuſted as before directed, you bring the teleſcope down ſo as to look directly at your meridian mark; and then you ſet it to the declination, and right aſcenſion, as before-mentioned.

"By this inſtrument moſt of the ſtars of the firſt and ſecond magnitude have been ſeen even at mid-day, and the ſun ſhining bright; as alſo Mercury, Venus, and Jupiter: Saturn, and Mars are not ſo eaſy to be ſeen, upon account of the faintneſs of their light, except indeed when the ſun is but a few hours above the horizon.

"And in the ſame manner in the night-time, when you can ſee a ſtar, planet, or any new phenomenon, ſuch as a comet, you may find its declination and right aſcenſion immediately, by turning about the equatorial handle, and declination handle, till you ſee the ſtar, planet, or phenomenon; and then looking upon the equatorial plate, you find its right aſcenſion in time; and you find upon the declination-ſemicircle its declination in degrees and minutes.

"In order to have the other uſes of this inſtrument, you muſt make the equatorial plates become parallel to the horizontal plates; and then this inſtrument becomes an equal altitude inſtrument, a tranſit inſtrument, a theodolite, a quadrant, an azimuth inſtrument, and a level. The manner of applying it to theſe different purpoſes is too obvious to need any explanation.

"As there is alſo a box with a magnetic needle faſtened in the lower plate of this inſtrument, by it you may adjuſt the inſtrument nearly in the meridian; and by it likewiſe you may find the variation of the needle; if you ſet the horizontal meridian, and the equatorial meridian, in the middle of their verniers, and direct your teleſcope to your meridian mark, you obſerve how many degrees from the meridian of the box the needle points at: and this diſtance or difference is the variation of the needle."

Theſe are the uſes to which Mr. Short's inſtrument, before us, was principally applied, and had the circles been divided with verniers ſubdividing the diviſions more minutely, it would have been ſomething more than an aſtronomical play-thing, to which it cannot be conſidered as any thing ſuperior, when it comes to be contraſted with one of the moſt improved kind, even of thoſe that are equally portable. We cannot diſmiſs our notice, however, of the preſent inſtrument, without remarking further, that the manner in which the two pairs of plates A A, and F F, move over each other reſpectively, is by no means calculated to preſerve a ſteady undeviating motion, for want of a ſufficient length in the axis of motion. This is the principal objection we expreſſed to Dr. Wollaſton's circle made by Mr. Cary, and if the doctor borrowed his notion of ſuch a poſition of his circles from Mr. Short, he copied one of the worſt properties that this artiſt's inſtrument poſſeſſes.

This equatorial inſtrument has obtained the name of univerſal, from the circumſtance of its being applicable to uſe in any latitude; which name is equally due to its ſucceſſors.

Portable Equatorial Inſtrument by Mr. Ed. Nairne.—The imperfections of the preceding inſtrument were attempted to be removed by Mr. Nairne, whoſe conſtruction introduced a long axis of motion for the horizontal circle, thereby effecting a ſteadineſs in its performance, and placed the teleſcope on the axis of the declination-ſemicircle to obtain a leſs encumbered elevation of the teleſcope; but ſtill the circles were not graduated ſo minutely as to render them of real uſe in practical aſtronomy. A brief account of this inſtrument is contained in vol. lxi. part i. of the Philoſophical Tranſactions of London, and was read before the Society on Feb. 7, 1771. Its ſubſtance is this:—

The inſtrument conſiſts of the following parts, *Plate* XII. *fig.* 1. of *Aſtronomical Inſtruments*, a mahogany triangular ſtand A A A, and three adjuſting ſcrews B, B, B, a moveable azimuth circle C, which is divided into degrees, and by a vernier index into every ſix minutes; above this azimuth circle is the horizontal plate D, to the under part of which is faſtened the vertical conical axis E; on the middle of the upper ſurface of the horizontal plate is placed a ground glaſs level F, by which the plate D is ſet parallel, and the pillar E perpendicular to the horizon; from this plate riſe perpendicularly two quadrants G, G, one of which is divided for the latitude into half degrees, and has a vernier index to three minutes; the equatorial plate H, with its hour circle, is ſupported by the two quadrants G, G, its axis of motion, which is placed near the hours XII, XII, paſſes through the centres of the quadrants, and carries the index I, pointing to the divided quadrant; the equatorial plate is divided into half degrees, and has a vernier index ſhewing every three minutes of right aſcenſion, or 12 ſeconds of time; it is figured to ſhew both degrees and time. To prevent miſapprehenſion it may be right to remark that the hours XII, XII, ought properly to have been placed according to the meridian line; but they are here placed otherwiſe for the convenience of better ſeeing the meridian diſtance ſhewn by the vernier. On the upper part of the equatorial plate is the plate K; upon this plate K are fixed the two ſupporters M, M, which ſupport the axis N, *under* which is faſtened the ſemicircle of declination O, divided into half degrees with a vernier ſubdividing it into every three minutes. On the *upper* part of this axis is fixed an achromatic teleſcope P, which magnifies about 50 times; to the eye-end of this teleſcope is applied a ſmall reflecting ſpeculum, making an angle of 45° with the axis of the teleſcope, whereby objects that are in the zenith or in any other altitude may be obſerved without putting the body in an inconvenient poſition. To the under part of the axis N is faſtened a braſs arm carrying the weight Q, which counterbalances the teleſcope, and braſs-work annexed to it; whilſt the weights R, R, counterbalance in like manner the whole of the inſtrument that is moveable on the equatorial axis, ſo that whatever poſition the inſtrument is put in it will there remain, being perfectly balanced. The four motions of this inſtrument may, when required, be moved extremely ſlowly, by means of the indented edges of the circles and ſemicircles, and the ſcrews or worms of the handles S, T, V, and W, for the horizontal circle, the motion for latitude, the equatorial and declination motions reſpectively. The adjuſtments and uſes of this inſtrument are ſo ſimilar to thoſe of its predeceſſor, both in kind and extent, that it would be ſuperfluous to particularize them again. In this account it is not ſtated whether the axis of motion of the equatorial circle is prolonged,

longed, but as the height to which it is elevated above the horizon circle ſeems to admit of it, and as the axis of this is elongated, we are diſpoſed to believe that a ſimilar advantage belonged to the former; otherwiſe it would not have that ſtability that is neceſſary in this part of the inſtrument for making the moſt eſſential motion ſteady enough to be depended on. How far the mahogany legs were firm and ſteady enough for the purpoſe of affording a motionleſs pedeſtal is not ſaid; but the want of accuracy, or rather the want of minuteneſs in the diviſions and ſubdiviſions of the graduated circles, quadrant, and ſemicircle, made this conſideration of leſs importance than it would have been in an inſtrument poſſeſſing greater powers. We have been informed, from credible authority, that Mr. W. Ludlam, of St. John's college, Cambridge, was the principal contriver of Mr. Nairne's conſtruction.

Ramſden's portable equatorial inſtrument.—The principal parts of this inſtrument, ſays profeſſor Vince, (Treatiſe on Prac. Aſtr.) are, the azimuth circle G H, the equatorial, or hour circle E F, and the declination circle C D; (ſee *Plate* XI. *fig.* 2. of *Aſtronomical Inſtruments*,) to this latter there is fixed a teleſcope A B, having under it a rod *m n*, paſſing through two pieces π, ρ, in one of which, as π, are two ſcrews acting on the rod againſt each other, in order to adjuſt the rod perpendicular to the axis on which the declination circle turns. The azimuth circle G H lies on a braſs plate *t u*, ſupported by three feet, reſting on the ſcrews X, Y, Z, and on this plate it turns about an axis T, by means of a ſcrew S; upon this circle are placed two ſpirit levels *c d*, *a b*, at right angles to each other, ſupported at each end by a ſcrew, by which they may be adjuſted; the circle is divided into twice 180°, and has a vernier V fixed on the plate *t u*, by which the degrees are ſubdivided into minutes or half minutes, according to the ſize of the inſtrument; and by means of the ſcrew I the circle may be fixed to the plate *t u*. K K is a polar axis moveable about a centre L, ſuſtained by two ſupporters *q*, *i*, reſting on two pieces W, V, firmly connected to the plane of the circle G H; the lower end of this axis has an arc fixed to it, which runs againſt an arc *z y*, attached to G H, and to which it may be fixed by a key at *e*; and in this ſituation, if you apply the key to Q, it gives a motion to the axis, by which you may very accurately adjuſt the teleſcope to an object. To the centre L, and perpendicular to the polar axis, are fixed two ſtrong pieces of braſs, one of which is here repreſented by *x*, and the other is on the other ſide of the axis; theſe ſupport a circle $\alpha\ \beta\ \gamma\ \delta$; on the top of the polar axis, and perpendicular to it, is placed a braſs plate, moveable about a pivot on the top of the axis; to this are fixed four pieces, two of which are repreſented by *f*, *g*; theſe are connected to the hour circle E F, lying on $\alpha\ \beta\ \gamma\ \delta$, and carry it about; upon $\alpha\ \beta\ \gamma\ \delta$, at W, is fixed a vernier to the circle E F, which circle is divided into twice twelve hours. The declination circle C D is ſupported by its centre, on an axis reſting on two ſupporters *h*, *k*, on one ſide, and two others of the like kind on the other; theſe reſt upon the braſs piece on the top of the polar axis, and may be adjuſted by two pair of ſcrews at the feet of the two ſupporters, to ſet the plane of the declination circle perpendicular to the hour circle, which, by the maker, is placed perpendicular to the polar axis. This circle is divided from zero both ways to a little more than 90°, and a vernier is placed at R to ſubdivide, as at V. A ſmall quadrant is fixed to the eye-piece of the teleſcope, which turns round upon the piece, carrying two wires perpendicular to each other, for the parallel of declination and hour circle. The eye-piece carries two croſs wires to repreſent the circle of altitude and a parallel to the horizon. The quadrant has two radii *l*, *o*, perpendicular to each other, and move together; the former has a round or circular ſpirit level upon it, ſo that by turning about the eye-glaſs and the quadrant till the bubble reſts in the middle, the plane of the quadrant becomes perpendicular to the horizon; and the vernier on the latter ſhews the altitude to which the teleſcope is directed, and the correſponding refraction; and in this poſition the circle of altitude is perpendicular to the horizon. At P is a ſmall micrometer circle, called the refraction circle, (with a fixed index,) moveable by a finger ſcrew; this circle is divided into half minutes, and one revolution is equal to 3′ 18″; when moved it raiſes or depreſſes the centre of the croſs wires in a circle of altitude.

After this general deſcription of the parts of the inſtrument, let us conſider what motions it is capable of, and what the circles may be made to repreſent, before we proceed to its adjuſtments. And firſt, the azimuth circle G H, being ſet parallel to the horizon, will repreſent the horizon; ſecondly, if the polar axis K K be inclined to the horizon at an angle equal to the latitude of the place, the equatorial circle E H will be inclined to the horizon in an angle equal to the inclination of the equator to the horizon; therefore, if we turn about the azimuth circle, and conſequently the equatorial circle, the latter may be made to coincide with the equator; thirdly, if the declination circle be ſet perpendicular to the equatorial, then the conſequences muſt be, that if the line of collimation be adjuſted parallel to the plane of the declination circle, or perpendicular to its axis, and alſo parallel to the equatorial circle E F, when zero on the declination circle coincides with zero on the vernier R, then the teleſcope is directed to the equator in the heavens, and by turning about the declination circle the line of collimation will deſcribe a ſecondary to the equator; and by ſetting the declination circle to the declination of any body in the heavens, if we turn about the circle E F, and conſequently the circle C D with the teleſcope, on the braſs plate, on the top of the polar axis (which is kept fixed,) the equatorial circle, moving in its own plane perpendicular to the polar axis, muſt continue to coincide with the equator, and, conſequently, the teleſcope will deſcribe a parallel to the equator, and therefore muſt bring the body into the field of view. Theſe being the motions of the parts of the inſtrument, we may now proceed to deſcribe the neceſſary adjuſtments for them.

Adjuſtments.—1. *To adjuſt the azimuth circle parallel to the horizon.*—Turn it till one of its levels becomes parallel to a line joining two of the ſcrews at the feet, as X, Z, and then adjuſt that level with one of them; turn the circle half round, and if the bubble be not in the middle, adjuſt it half way, by one of the above-mentioned ſcrews, and half way by the ſcrew at one end of the level; repeat this operation till the bubble ſtands right in both theſe poſitions; then turn the circle at right angles to theſe poſitions, and, if neceſſary, ſet the bubble right by the other ſcrew Y at the foot, and the adjuſtment is made. If you previouſly adjuſt the other level by one of the ſcrews at the end, then the circle may be adjuſted horizontal by them, without turning it.

2. *To adjuſt the level* r s *parallel to the rod* m n.—Set the polar axis, as nearly as you can, perpendicular to the horizon, and turn about the declination circle C D by a pinion for that purpoſe, until the bubble of the level *r ſ* ſtands in the middle; reverſe the level, and if the bubble do not ſtand in the middle, adjuſt it half way by the ſcrew at S, under

one end of the level, and half way by turning the declination circle; and repeat the operation till the bubble ſtands in the middle in both poſitions.

3. *To adjuſt the rod* m n *perpendicular to the axis on which the declination circle turns.*—Set the polar axis as near as you can parallel, and conſequently the equatorial circle perpendicular to the horizon; ſet the declination circle to zero, and turn the hour circle till the bubble ſtands right; then ſet the declination circle to 90°, and adjuſt the bubble by the polar axis: then turn the declination circle to the oppoſite 90°, and if the level be not right, correct half the error by the polar axis, and the other half by the two ſcrews in the piece π, releaſing one and ſcrewing up the other; repeat this operation till the bubble ſtands right in both poſitions, and the adjuſtment is made. For theſe two adjuſtments tend, the former to ſet the axis of the declination circle, on the axis about which the rod revolves, perpendicular to the horizon: and the other to ſet the rod *m n* parallel to the horizon, and conſequently perpendicular to that axis; when, therefore, the bubble thus continues right, both circumſtances muſt have taken place.

4. *To ſet the axis of the declination circle perpendicular to the polar axis.*—The inſtrument remaining as in the laſt adjuſtment, that is, the declination circle at 90° and the bubble right, turn the equatorial circle half round, and if the bubble be not right, correct half the error by the polar axis, and the other half by the two pair of ſcrews at the feet of the two ſupporters *h, k*; and repeat this operation till the bubble is right in both poſitions, and the adjuſtment is completed. For the former adjuſtment tends to ſet the axis of the declination circle perpendicular to the horizon, and the latter to ſet it parallel to the equatorial circle, or perpendicular to the polar axis; conſequently, when the bubble is right in both the above poſitions both circumſtances muſt take place, that is, the polar axis muſt be parallel to the horizon, and the axis of the declination circle perpendicular to it. And as this adjuſtment is made by the level, which is horizontal when the axis of the declination circle is thus adjuſted perpendicular to the horizon, and which is previouſly adjuſted parallel to the rod, they muſt both be perpendicular to the axis, about which they turn; and, conſequently, they move in a plane paſſing through the polar axis, or perpendicular to the equatorial circle. Hence, alſo, the declination circle, being perpendicular to its own axis, becomes perpendicular to the equatorial circle.

5. *To make the centre of the croſs wires cut the ſame object whilſt you turn round the eye-glaſs by the pinion of the refraction apparatus.*—Set the index on the refraction circle to the beginning of the diviſions, and turn round the eye-glaſs, and if the centre of the wires do not continue to cut the ſame object, correct it by four ſmall ſcrews (which you will find by unſcrewing the neareſt end of the eye-tube which contains the firſt eye-glaſs), the two oppoſite at a time, and repeat the correction till the centre continues to cut the ſame object.

6. *To make the line of collimation deſcribe a great circle perpendicular to the equatorial circle.*—Set the declination circle to 90°, and the equatorial circle to VI, and bring the bubble to the middle by the polar axis. Then note ſome object covered by the centre of the croſs wires, repreſenting the parallel of declination and hour circle, and turn the equatorial circle half round, and if the ſame object be not now covered by the centre of the wires, move, if neceſſary, the declination circle in its own plane, until it is in the ſame vertical circle with the object, and then bring the centre half way to it by the upper and lower of the four ſmall ſcrews which move theſe wires, and turn the declination circle back through half the ſpace it was moved, and you get a new object, now covered by the centre of the wires; repeat this operation till the ſame object be covered in both theſe poſitions; then ſet the hour circle to XII, and bring the bubble to the middle by the declination circle, and if the centre do not now cover the ſame object, bring it to the object by the other two ſcrews, and the line of collimation is adjuſted parallel to the level, or to the rod *m n*, and, conſequently, it muſt be perpendicular to the axis of the declination circle. Hence as that circle is turned about in its own place, the line of collimation muſt deſcribe a ſecondary to the equator. The line of collimation for the centre of the croſs wires being thus adjuſted, it is, at the ſame time, in the centre of motion, on which the wires parallel and perpendicular to the horizon turn; hence, when the index of the refraction circle is ſet to the beginning of the diviſions, the interſections of the two ſets of wires coincide. The adjuſtment of the wire parallel to the equatorial circle may be examined by the paſſage of a ſtar through the teleſcope, (all the other adjuſtments being previouſly made, and the equatorial circle adjuſted to coincide with the equator in the heavens, and the declination circle ſet to the ſtar's declination;) for if the ſtar do not run upon the wire, it muſt be adjuſted till it does: or it may be done thus. Set the equatorial circle to XII, and having directed the line of collimation to ſome ſmall well defined object, turn the declination circle in its own plane, and obſerve whether the perpendicular wire continue to cut the ſame object as it paſſes through the field of view; if not, adjuſt till it does.

7. *To adjuſt the verniers of the equatorial and declination circles.*—Elevate the equatorial circle to an angle of about 45°, as moſt proper for this purpoſe, and ſet the declination circle to zero, and turn the equatorial circle in its own plane till the bubble ſtands right; then turn the equatorial circle half round, and if the bubble do not ſtand right, adjuſt half by moving the equatorial, and half by moving the declination circle; and repeat this operation till the bubble ſtands right in both poſitions, then, by moving the verniers, ſet zero on the vernier belonging to the equatorial circle to VI, and zero on the vernier belonging to the declination circle to zero, and the verniers are adjuſted. Thus the inſtrument is ready for obſervation, except that the azimuth circle is not adjuſted to ſhew azimuths, which will be done when we come to ſhew the methods of making obſervations.

The method here uſed ariſes out of the two diſtinguiſhing features of the inſtrument under our conſideration; namely, the poſition of the level near the teleſcope, and the want of graduations on the latitude arch, or arch for giving the polar axis its due inclination.

But the Hon. Mr. M'Kenzie's method appears to us more ſimple, as well as more intelligible, for elevating the equatorial circle to the co-latitude of the place, thus; "lower the teleſcope as many degrees, minutes, and ſeconds below zero, on the declination-ſemicircle, as the complement of your latitude is; then elevate the polar axis till the bubble be horizontal, and the equatorial circle will be elevated to the co-latitude of the place, as required; after which the level may be made to ſtand true in oppoſite poſitions, and the verniers be placed to zero, as above directed.

Mr. Atwood, in his Syllabus, has given another method of making this adjuſtment, which profeſſor Vince acknowledges to have the advantage over his in point of both eaſe and accuracy, the ſubſtance of which is as follows:

Having ſet the declination circle to 90° in either quadrant, direct the point of interſection of the croſs-wires to coincide with ſome diſtant object as a mark; turn the equatorial circle in its own plane 180°, and if the interſection does not now coincide with the diſtant mark, correct half the error in declination by moving the declination circle in its own plane, and half the error in right aſcenſion by the feet ſcrews of the ſupporters that adjuſt the axis of the declination circle; now if theſe adjuſtments be accurately made, the interſection will coincide with any diſtant mark, choſen anew, when the equatorial circle has been turned 180°; but if the coincidence is not perfect, the ſame adjuſtments muſt be repeated till the condition is fulfilled. The line of collimation being now directed to coincide with the diſtant mark, ſet the vernier of the declination circle to 90°, and turn this circle 180° in its own plane, turn alſo the azimuth circle, ſo that the line of collimation may be again directed to the ſaid diſtant mark, then turn the equatorial circle about in its own plane 180°, and if the diſtant mark be not now covered by the interſection, the quantity of deviation ſhews double the total error of dividing the two ſemi-circles of the declination circle, and alſo its excentricity, which errors cannot be allowed for by adjuſtment. The error in right aſcenſion, now diſcovered, muſt ariſe from the plane of the declination circle not being quite perpendicular to the equatorial, and alſo from the line of collimation not being exactly parallel to the plane of the declination circle; therefore correct $\frac{1}{4}$th of the error by the ſcrews of the declination axis, and $\frac{1}{4}$th by moving the line of collimation perpendicular to the plane of the declination circle: if the firſt trial of theſe adjuſtments be not attended with complete ſucceſs, when the diſtant mark is again examined in reverſed poſitions they muſt be repeated till they are correct. Hence it is manifeſt, when the above adjuſtments are properly made, 1ſt, that the line of collimation is parallel to the plane of the declination circle; 2dly, that the plane of the declination circle is perpendicular to the plane of the equatorial; 3dly, that the errors of diviſion are at the oppoſite points 90°, if any are diſcovered in the declination circle, and, 4thly, that when the declination circle is ſet to 90°, the line of collimation is perpendicular to the plane of the equatorial circle, or, when it is ſet to zero, it is parallel to it.

The azimuth circle being adjuſted horizontal, and the declination circle put to 90°, make the vertical wire parallel to it, turning the equatorial and azimuth circles in their reſpective planes; direct the point of interſection to a diſtant mark near the horizon, and move the azimuth and declination circles each in their own planes to 180°, ſo that the ſaid mark may appear ſomewhere in the vertical wire, and if there is an error in altitude, let the line of collimation biſect it, by moving the polar axis, and it will then be horizontal. Let this new biſected point or mark in the horizon be noted; then the declination circle being put to zero, turn the azimuth circle 90°, ſo as to bring the new mark upon the croſs wire, and direct the interſection to it by turning the equatorial circle in its own plane, and the declination is in that ſituation parallel to the horizon. The inſtrument remaining as before, turn the equatorial and azimuth circles in their reſpective planes 180°, and if each circle be accurately divided, the teleſcope muſt evidently be brought into a poſition exactly parallel to its former one, and therefore the interſection of the wires will again coincide with the new mark in the horizon. Otherwiſe the quantity each of thoſe circles muſt be moved further or back, will ſhew their reſpective errors of excentricity and alſo of diviſion. Laſtly, the declination circle being at zero, and the line of collimation or interſection made to coincide with the horizontal mark, by moving the equatorial and azimuth circles, ſet the equatorial vernier to VI, and the adjuſtment is finiſhed; for the line of collimation being parallel to the horizon, and to the plane of the declination circle when the vernier ſtands at VI, that plane, by revolving about the polar axis, muſt be perpendicular to the horizon when the vernier ſtands at XII, which is the thing required.

Methods of making Obſervations.

1. *To take the altitude of a body above the horizon.*—Set XII on the equatorial circle to zero on its vernier, and the plane of the declination circle is then perpendicular to the horizon; make, therefore, the line of collimation horizontal, by bringing the bubble to the middle of the level in the teleſcope, and obſerve what point of the declination circle ſtands againſt zero in its vernier, and then by moving the declination and azimuth circles in their own planes, bring the body to the centre of the croſs wires, and obſerve again what point of the declination circle ſtands againſt zero, and the arc intercepted between theſe two points gives the apparent altitude. If the declination circle had been ſet to zero, and the line of collimation been adjuſted horizontal by moving the polar axis, then, when the body had been brought to the centre of the croſs wires, the declination circle would have ſhewn its altitude at once. For Mr. Atwood's indirect methods of taking an altitude, ſee pages 163, 164, and 165 of Vince's "Treatiſe on Practical Aſtronomy."

2. *To meaſure very ſmall vertical angles.*—Let the elevation of the equatorial circle be a, the polar diſtance of the teleſcope (either more or leſs than 90°) be b, and ſet XII (correſponding to noon) on the equatorial circle to zero; then if that circle deſcribes an angle whoſe verſed ſine is v, and the line of collimation be brought (by moving the azimuth circle) back to the ſame vertical, it will have been depreſſed through a vertical arc equal to $\frac{v \times si.a \times si.b}{si.b - a}$, radius being unity. Or, if $b = 90°$, the depreſſion $= v \times \tan. a$. Hence if, for example, it ſhould be required to find the angle which the horizontal wire of the teleſcope ſubtends, ſelect ſome well defined diſtant object, ſet the declination circle to zero, and XII on the equatorial to zero, and elevate the equatorial ſo as to bring the object into the field of view, and make the upper edge of the wire coincide with it, then move the equatorial and azimuth circles in their own planes till the lower edge coincide with it, and read off the equatorial arc. *Ex.* If the elevation of the equatorial be 41° 3′, and the arc denoted by the equatorial vernier be 57′, the angle required = vec. ſin. $57' \times \tan. 41° 3' = 24'' 6'''$. Hence alſo the diameter of a planet may be meaſured. When the planet comes to the meridian (the two circles being fixed as before) alter the elevation of the equatorial circle, and bring the upper edge of the horizontal wire to be a tangent to the upper limb of the planet (or the apparent lower limb), and then by turning the azimuth and equatorial circles in their own planes, bring the lower edge of the wire to be a tangent to the lower limb of the planet (or the apparent upper limb), and the rule gives the ſum of the diameters of the planet and wire, from which ſubtract the diameter of the wire, and you get the diameter of the planet.

3. *To find the latitude of a place.*—Take the altitude of the ſun's upper or lower limb a little before noon, and continue your obſervation till he riſes no longer, and you get

his apparent meridian altitude; with which and his declination you may ſind the latitude by the common rule.

4. *To incline the equatorial circle ſo as to make any angle with the horizon.*—Set the declination-circle (in the ſouthern quadrant) to the given angle, and XII on the equatorial circle to zero on its vernier; then bring the line of collimation horizontal by moving the polar axis till the bubble in the level on the teleſcope ſtands in the middle, and the equatorial circle ſtands at the proper angle.

5. *To determine the poſition of the meridian.*—Elevate by the laſt article the equatorial circle, to make an angle with the horizon equal to the co-latitude of the place, and ſet the declination-circle to the declination of any known ſtar, then turn the equatorial and azimuth-circles in their own planes till the ſtar is brought to the centre of the croſs wires, and correct the poſition of theſe circles on account of refraction, by the ſmall quadrant and apparatus at the eye-piece of the teleſcope, and the equatorial circle will then coincide with the equator in the heavens, and the vernier will ſhew how far, in time, the ſtar is from the meridian; and hence, if we turn the equatorial circle till XII ſtands at zero on the vernier, the plane of the declination-circle will coincide with the meridian. Hence, if we direct the teleſcope to the horizon, the point which the centre of the wires will cut is the ſouth point of the horizon, and may ſerve for a meridian mark. If the point of the arc of the azimuth-circle lying againſt zero on its vernier be noted, the error in its poſition will be known; and if this be very ſmall, ſo that by moving the vernier till zero on it may be brought to zero on the arc, it may be adjuſted to ſhew azimuths. The poſition of the vernier of the azimuth-circle may alſo be verified thus. The equatorial-circle being ſet parallel to the horizon, and XII ſet to zero on its vernier, turn the azimuth-circle, and by moving the declination-circle, bring a ſtar on the eaſt ſide of the meridian to the centre of the croſs wires, and note the azimuth, then turn the azimuth-circle (the teleſcope remaining fixed) and do the ſame when the body comes to the weſt ſide; and if the azimuths at both obſervations be the ſame, the vernier is adjuſted right; if not, half their difference is the error. The inſtrument being ſet upon a moveable plane, if the points on which the three ſcrews at the feet reſt be marked, it will then always be eaſy to ſet the azimuth-circle very nearly in its proper poſition.

6. *To determine the apparent time of the day.*—Proceed as in the laſt article, only take the ſun inſtead of a ſtar, and bring its centre to the centre of the croſs wires, and correct for refraction, and the arc intercepted between XII and zero on the vernier ſhews the diſtance of the ſun, in time, from the meridian, or from apparent noon.

7. *To find a ſtar or planet in the day-time.*—Elevate the equatorial-circle to make an angle equal to the co-latitude, and adjuſt it to coincide with the equator in the heavens, and ſet the declination-circle to the declination of the body. Find by the uſual way the diſtance of the ſtar from the meridian at the time required, and reduce it to ſiderial time; then turn the equatorial-circle in its own plane, eaſt or weſt, as the ſtar lies, till the arc between XII and zero on the vernier be equal to that time, and the ſtar will be in the field of view. By this means Jupiter, Venus, and fixed ſtars of the firſt magnitude, may be obſerved in the day-time.

8. *To find the right aſcenſion and declination of a ſtar.*—Elevate the equatorial-circle to the co-latitude of the place, and previouſly ſet it to coincide with the equator in the heavens, and ſet XII on the equatorial-circle to zero on its vernier. After this ſet the declination-circle to the ſun's declination, and take the time of its tranſit; then ſet the declination-circle to the ſtar's declination and take the time of its tranſit, and the difference of the times will give the difference of their right aſcenſions; and the ſtar's tranſit being taken at the interſection of the wires, the declination-circle (corrected for refraction) will give its declination. Thus alſo you may compare two ſtars, or the moon and a ſtar. Or it may be done at any time, if you move the declination and equatorial-circles in their own planes till the ſtar is brought to the centre of the croſs wires, and correct the poſition of theſe circles on account of refraction, and the declination-circle will give you the declination required; and the vernier of the equatorial-circle will give you the ſtar's diſtance, in time, from the meridian, or your clock will give you the ſun's diſtance, the difference of which times gives the difference of their right aſcenſions, and, therefore, knowing the ſun's right aſcenſion, you have the right aſcenſion of the ſtar.

9. *To find the longitude.*—The equatorial-circle being ſet to coincide with the equator in the heavens, and XII to zero on its vernier, take the time of the tranſit of the moon's limb, and alſo of a proper ſtar as near as poſſible to the moon's parallel, and the longitude may be determined therefrom by the lunar method, in the uſual way.

10. *To meaſure horizontal angles.*—Adjuſt the equatorial-circle parallel to the azimuth-circle; and having directed the line of collimation to one of the objects, move the equatorial-circle in its own plane, and alſo the declination-circle, if neceſſary, and bring the line of collimation to the other, and the arc through which the equatorial-circle has moved gives the angle required.

As an appendage to this account, by profeſſor Vince, of Ramſden's portable equatorial inſtrument, we think it may be acceptable to our readers to have the Hon. S. M'Kenzie's account of Mr. Ramſden's new refraction apparatus much improved, which was publiſhed in his anonymous pamphlet, (dated in the year 1791, a year after the profeſſor's treatiſe was publiſhed), together with the explication of the principles on which the apparatus was conſtructed.—"Refraction or parallax," ſays our author, "by changing the apparent altitude of a planet, may alſo change its apparent right aſcenſion and declination; ſee *fig.* 2. of *Plate* XII. (of *Aſtron. Inſt.*) where H O repreſents the horizon; E Q, part of the equator; P, the pole of the equator; Z, the zenith; P E H, the meridian; Z V, an arc of a vertical drawn through I, the *apparent* place, and F, the *true* place of the planet; P A, a circle of declination, or hour-circle, drawn through the true place F; and P B, a circle of declination or hour-circle drawn through the apparent place I. The error in altitude from F to I alters the right aſcenſion of the planet as much as the arc of the equator A B, or its parallel F C, amounts to. It alſo alters its declination from A F to B L, that is, from C to I. If a planet be in the meridian at L, the error, in declination from L to K, will be the ſame as the error in altitude; but there will be no error in right aſcenſion, becauſe the ſame circle of declination P E H, (perpendicular to the horizon,) paſſes through the apparent place K, and the true place L. In like manner, if by the conſtruction of an inſtrument you have a vertical circle Z V, perpendicular to the horizon, it will paſs through the apparent place I and the true place F, and there will be no error in right aſcenſion; and if by the ſame inſtrument the error in altitude from F to I be determined, the true place F is found, and conſequently there will be no error in declination. With Mr. Ramſden's new refraction apparatus you have juſt ſuch a vertical circle as will appear from what follows.

In the focus of the teleſcope of the equatorial two *fixed* wires are placed at right angles to each other; one, E Q, (ſee *fig.* 4.) repreſents part of a parallel of the equator; the other, P A, part of a meridian, or hour-circle. There are alſo two moveable croſs wires at right angles to each other; one, H O, repreſents a portion of a parallel to the horizon; the other, Z V, a portion of a vertical circle. Theſe moveable wires have a motion round the axis of the teleſcope, by turning a pinion.

A ſmall quadrant (ſee *Plate* XI. *fig.* 2. and alſo *Plate* XII. *fig.* 2.) is fixed on the part that carries the moveable wires, with diviſions on each ſide; one expreſſing the degree of altitude of the object viewed, the other expreſſing the minutes and ſeconds of error occaſioned by refraction, correſponding to that degree of altitude. To the index of this quadrant is fixed a ſmall circular level, which being adjuſted by its own pinion, gives the altitude; while by another pinion it aſcertains the perpendicularity of one of the moveable wires, which gives the vertical circle abovementioned, whereby the true right aſcenſion may be determined, free from all error ariſing from refraction or parallax. Hence, in taking the moon's right aſcenſion with an equatorial inſtrument, fitted with this refraction apparatus, in order to determine longitudes at land, there is no occaſion to attend to her parallax, as the difference of her right aſcenſion, cauſed by parallax or refraction, will only depreſs or elevate her on the ſame vertical circle, but will not change her right aſcenſion from one hour-circle to another. In this refraction apparatus the centre of the fixed wires always remains in the line of collimation; whereas by the former conſtruction, on raiſing or depreſſing that centre, it was moved out of that line; and as it was very difficult to replace it exactly, an error in the obſervation was liable thereby to be produced. In all obſervations made with this refraction apparatus, firſt adjuſt the circular-level, then ſet the centre of the moveable wires, by the micrometer ſcrew, to the refraction correſponding to the altitude of the object viewed, as given by the ſmall quadrant; and let one of the moveable wires be ſet always perpendicular. Since copying the preceding extract from Mr. M'Kenzie's pamphlet, we have been aſſured that it was publiſhed previouſly to profeſſor Vince's treatiſe, and that the date 1791 is a typographical error for 1771; accordingly, we learn from Mr. Dollond, that Ramſden's inſtrument preceded his, but our inquiries to obtain the *preciſe time* of its origin have not been ſucceſsful. The two different ſizes of Ramſden's portable inſtrument were according to the following table of dimenſions.

	Rad. in In.	Limb divided to	Vernier of 30 gives	Divided to parts	By vernier into
Azim. or horizontal circle,	5.1 2.7	15' 30	0° 30" 1' 0"	45th of in. 42d ditto	1350th 1262

Vertical ſemicircle for declination or latitude,	5.5 2.75	15 30	30" 1'	42d ditto 41st ditto	1260 1230

Portable Equatorial Inſtrument by Meſſrs. P. and J. Dollond.—Mr. Dollond informs us that his father contrived the inſtrument, which now comes under our notice, in or about the year 1775, and the readineſs with which he communicated all the particulars we wiſhed for reſpecting it deſerves our grateful acknowledgment. This inſtrument, ſays the author, (in his quarto pamphlet,) which of all others is the moſt amuſing to lovers of aſtronomy, is now rendered, by the following improvements, greatly ſuperior to any hitherto produced. As the whole weight does not exceed thirty pounds, it may be ſaid to be truly portable, yet, by the ſteadineſs of all the parts, and the perfection of the achromatic teleſcope, the obſervations may be made to a very great exactneſs. The focal length of the achromatic object-glaſs is about 17 inches; it is compoſed of three glaſſes, and admits of an aperture of two inches. The tube being made as thin as poſſible, is eaſily balanced by the weight A, which is fixed in the ſemi-circle B B; (ſee *fig.* 3. of *Plate* XI.) then again all the parts above the horizontal axis (the end of which is ſeen as C) are balanced by the ſquare weight D. By means of theſe balances the centre of gravity is preſerved over the centre of the inſtrument in every poſition, and the different parts prevented from being ſtrained when the inſtrument is put into any oblique poſition, which may be required in its various uſes. This alſo tends to keep the teleſcope ſteady, which is of the greateſt advantage in making an obſervation. Beſides theſe very eſſential improvements, every part has been reduced to the moſt ſimple ſtate; and ſeveral, which in other inſtruments of this kind, were found ſuperfluous, have been entirely rejected.

The inſtrument is ſupported by three feet E, E, E; the ſcrews *a*, *a*, *a*, are to raiſe or depreſs the feet, in order to bring the plate G G into an horizontal poſition, which is determined by two ſpirit-levels *b*, *b*, that are fixed on it at right angles to one another. If theſe levels are well adjuſted, the plate will be horizontal when the air-bubbles come into the middle of the glaſs tubes. As this plate repreſents the horizon of the place, it is called the horizontal plate: it is divided into half-degrees, and by a vernier *c* of thirty diviſions is ſubdivided to every minute. This index is made to move round the centre of the horizontal plate in order to ſet it to zero, or point 0, when that point is found to be in the plane of the meridian. The plate is moved round by turning the handle *d*. The worm-ſcrew, which works in the part *e*, may be eaſily diſengaged from the plate, when any conſiderable quantity is required to be moved at once. Preſs the handle *d* outwards, and the worm will be diſengaged. The plate F F is called the equatorial plate, as it repreſents the plane of the equator; it turns on the horizontal axis C, ſo that it may be inclined according to the latitude of the place, which is ſhewn on the latitude arch *f f*, that paſſes through the ſquare weight D: this arch is divided into 90°, and by the vernier is ſubdivided into every minute. The tube *g* is fixed to the horizontal axis, cloſe under the centre of the equatorial plate. An axis is fixed to the middle of the plate, which paſſes through the tube *g*, into a centre fixed in the ſquare weight; this axis tends greatly to ſecure the equatorial plate from ſwinging, when put into different inclinations, or when the teleſcope is turned into any oblique poſition.

The horizontal axis is made parallel to the horizontal plate by turning the ſcrew *h*, which will raiſe or depreſs that end of it. When the equatorial plate is inclined nearly to the latitude of the place, the clamp *i* may be tightened by the ſcrew at the ſide; then, by turning the finger-ſcrew *k*, it may be adjuſted to the greateſt exactneſs: the vernier *l* may be adjuſted, (in caſe any error ſhould be found,) by the ſmall ſcrews at *m*.

The equatorial plate is divided into twice XII hours;

theſe are ſubdivided into every two minutes of time, and by the vernier *n* again ſubdivided to every four ſeconds. This plate is moved round by turning the handle O. The worm-ſcrew which works in the edge may be diſengaged from the plate, by preſſing the handle O outwards.

Above this plate is the ſemi-circle B B, which is called the declination ſemi-circle; this is divided into twice 90°, and ſubdivided as the other circles are; it is fixed to the axis H, which may be made parallel to the horizontal axis by the ſcrew *p*, in the ſame manner as the horizontal axis is made parallel to the horizontal plate. On this declination ſemi-circle the teleſcope I I is ſupported, and being balanced by the weight A, is moved with the greateſt eaſe, by means of the pinion fixed at *q*, which is turned with the fingers at *r*.

To ſet the line of collimation of the teleſcope at right angles to the axis H, the wires in the eye-tube *s* may be moved in an horizontal direction by the ſcrews, which will be diſcovered when the part of the eye-tube *t* is taken off; this piece carries the eye-glaſs, and is made to ſlide on the part that contains the wires, that diſtinct viſion may be obtained by eyes of different convexities. There are four eye-tubes, intended for different purpoſes, producing magnifying powers from 40 to 60, and an eye-piece with a diagonal ſpeculum is ſometimes added for gaining a convenient view of ſtars near the zenith. There is a combination of lenſes to the number of four in one of theſe eye-tubes, and the enlargement of the field of view thereby affords a pleaſing view of the heavens. Beſides theſe, there is a ſliding piece containing ſmoaked glaſſes to guard the eyes of the obſerver from the ſun's rays, which glaſſes are ſmoaked but faintly at one end, and have the ſhade of darkneſs gradually increaſed towards the other to ſuit all ſtates of illumination. There is alſo a ſemi-ring fitted by friction to the tube of the teleſcope, near the object end, which bears an arm holding a ſmall diagonal reflector to direct the light of a lamp or candle into the tube ſo as to enlighten the croſs wires contained in one of the eye-tubes.

The compaſs box, placed on one ſide of the horizontal plate, is uſeful in aſcertaining nearly the meridian line, and alſo in detecting the variation of the magnetic needle at any time. Theſe were the original parts compoſing the inſtrument before us; and the inſtrument viewed as a whole piece of mechaniſm preſents a ſightly compact figure, but the circumſtance of the declination-ſemicircle, not allowing the teleſcope to reach as high as the pole, is an objection in the conſtruction of this inſtrument, which, we are obliged to confeſs, renders it of leſs value in our eſtimation than it otherwiſe would have been. When the inſtrument is to be adjuſted for obſervation, the horizontal plate is levelled by the levels in the firſt place, and then the equatorial plate is made parallel to the equator itſelf, by moving the ſquare weight along the arc *f f* till the vernier *l* marks the latitude of the place. The directions given for the uſes of Mr. Short's inſtrument will equally apply here as far as they go, but as this inſtrument profeſſes greater accuracy in the readings than that and Nairne's, it uſes are more extenſive; for it will ſerve occaſionally for an equal altitude inſtrument, a tranſit inſtrument, a quadrant or ſextant, an azimuth circle, a theodolite, and a level.

When this inſtrument is to be uſed for obſerving equal altitudes, bring zero on the equatorial plate to zero on the vernier *z*, by the handle O, and zero on the vernier *l* to 90° on the latitude arch, taking care that the clamp *i* is made faſt by the ſcrew at the ſide; adjuſt the horizontal plate very nicely by the two levels and feet ſcrews, then by turning the handles *d* and *r* bring the teleſcope to the ſun for the morning obſervations: in the afternoon ſet again the horizontal plate level, and the declination-ſemicircle to the degree and minute ſhewn at the correſponding morning obſervation; then bring the teleſcope to the ſun by turning the handle *d* only. In this manner ſeveral correſponding altitudes may be obſerved on the ſame day, and the inſtrument uſed in the mean time for other purpoſes. For the methods of making equal altitudes ſerviceable in the practice of nautical aſtronomy, ſee problems X, XI, XII, and XIII, in our article CHRONOMETER.

To convert this equatorial into a tranſit inſtrument, bring zero on the vernier *l* to 90° on the latitude arch, and fix the clamp *i*; level the horizontal plate, and bring the teleſcope to the meridian mark, ſuppoſed to be aſcertained, by turning the handles *d* and *r*: turn now the handle *r* alone, and it will raiſe the teleſcope in the plane of the meridian, ſo that when the ſun or ſtars are ſeen to paſs the vertical wire, they will then be upon the meridian, and the time may be noted accordingly. This application ſuppoſes of courſe the axes of the declination-circle perfectly parallel to the horizon plate, and alſo the line of collimation perfectly parallel to the ſame plate, but at right angles to the former, when the vernier is at zero. Theſe verifications, however, we think, demand the levels to be applied nearer to the teleſcope than on the horizon plate only.

When the inſtrument is in the poſition juſt deſcribed, let the moveable vernier *c* be put to zero on the horizontal plate and be made faſt, then turn the handles *d* and *r* to bring any celeſtial object into the field of view of the teleſcope, and its azimuth will be ſhewn on the horizontal plate, while at the ſame time its altitude will be indicated on the declination ſemi-circle.

When uſed as a theodolite, let this inſtrument have its horizontal plate levelled as before; then bring zero on the equatorial plate to zero on the vernier *z*, and alſo zero on the vernier *l* to 90° on the arc of latitude, and fix the clamp *i*. Turn the horizontal plate and declination-ſemicircle, ſo as to gain a view of the object whence the angle is to be meaſured; then bring the teleſcope to the ſecond object, by moving the equatorial plate and declination-ſemicircle without the horizontal plate, and this laſt plate will then ſhew the meaſure of the ſaid angle; and if there is any elevation or depreſſion of the latter object compared with the firſt, the declination-ſemicircle will point it out. The bearings, alſo, will be ſhewn by the compaſs, as in the common theodolite.

When zero on the ſemicircle is brought to zero on the vernier *y*, the inſtrument then becomes a level; ſo that by turning the equatorial plate round, an obſerver may ſee what objects are level with the teleſcope. For this purpoſe alſo, our opinion is, that the level would be much better applied parallel to the teleſcope, on the declination-ſemicircle itſelf.

The late Mr. John Dollond had invented his object-glaſs micrometer previouſly to his arrangement of the circles and other parts of his equatorial inſtrument, ſeeing Dr. Maſkelyne gave a paper on it to the Royal Society, which was read Dec. 12, 1771, which micrometer was ſometimes made an appendage to his equatorial; but as this addition is not peculiar to the inſtrument in queſtion, but may be applied to any other aſtronomical inſtrument, or even a common teleſcope, we will deſcribe it hereafter, under our article EQUATORIAL *Micrometer*. We muſt not, however, omit a notice of the refraction apparatus belonging to the equatorial inſtrument, as made by the Dollonds, an account of which was read before the Royal Society on March 4, 1779, as drawn up by Mr. Peter Dollond, and preſented by the aſtronomer royal. *Fig.* 3. of *Plate* XII. of *Aſtronomical Inſtruments*, is a repreſentation of this apparatus, detached from the object end of a teleſcope. The account itſelf, being ſhort, will admit of being tranſcribed.

" The refraction of the atmoſphere," ſays the author, " occaſions the ſtars or planets to appear higher above the horizon than they really are; therefore a correction for this refraction ſhould be made in a vertical direction to the horizon. The equatorial inſtrument is ſo conſtructed, that the correction cannot be made by the arches or circles which compoſe it, when the ſtar, &c. is in any other vertical arch, except that of the meridian; becauſe the declination arch is never in a vertical poſition but when the teleſcope is in the plane of the meridian.

" To correct this error, a method of moving the eye tube, which contains the wires of the teleſcope in a vertical direction to the horizon, has been practiſed: but as the eye-tube is obliged to be turned round, in order to move it in that direction in the different oblique poſitions of the inſtrument, the wires are thereby put out of their proper ſituation in every other poſition of the inſtrument, except when it is in the plane of the meridian; for the equatorial wire ſhould always be parallel to the equator, that the ſtar in paſſing over the field of the teleſcope may move along with it, otherwiſe we cannot judge whether the teleſcope be ſet to the proper declination, except at the inſtant the ſtar is brought to the interſection of the wires, which is only a momentary obſervation.

" The method I have now put in practice for correcting the refraction of the atmoſphere, is, by applying two lenſes before the object-glaſs of the teleſcope; one of them convex, and the other concave; both ground on ſpheres of the ſame radius, which in thoſe I have made is thirty feet. The convex lens is round, of the ſame diameter as the object-glaſs of the teleſcope, and fixed into a braſs frame, or apparatus, which fits on to the end of the teleſcope. The concave lens is of the ſame width, but nearly two inches longer than it is wide, and is fixed in an oblong frame, which is made to ſlide on the frame that the other lens is fixed into, and cloſe to it. Theſe two lenſes being wrought on ſpheres of the ſame radius, the refraction of the one will be exactly deſtroyed by that of the other, and the focal length of the object-glaſs will not be altered by their being applied before it: and if the centres of theſe two lenſes coincide with each other, and alſo with that of the object-glaſs, the image of any object formed in the teleſcope will not be moved or ſuffer any change in its poſition. But if one of the lenſes be moved on the other, in the direction of a vertical arch, ſo as to ſeparate its centre from that of the other lens, it will occaſion a refraction, and the image will change its altitude in the teleſcope. The quantity of the refraction will be always in proportion to the motion of the lens, ſo that by a ſcale of equal parts applied to the braſs frame, the lens may be ſet to occaſion a refraction equal to the refraction of the atmoſphere in any altitude. If the concave lens be moved downwards, that is, towards the horizon, its refraction will then be in a contrary direction to that of the atmoſphere, and the ſtar will appear in the teleſcope as if no refraction had taken place.

" There is a ſmall circular ſpirit level fixed on one ſide of the apparatus, which ſerves to ſet it in ſuch a poſition, that the centres of the two lenſes may be in the plane of a vertical arch. This level is alſo uſed for adjuſting a ſmall quadrant, which is fixed to it, and divided into degrees, to ſhew the elevation of the teleſcope when directed to the ſtar; then the quantity of refraction anſwering to that altitude may be found by the common tables, and the concave lens ſet accordingly, by means of the ſcale at the ſide, which is divided into half minutes, and, if required, by uſing a vernier, may be divided into ſeconds.

" It muſt be obſerved, that when a ſtar or planet is but a few degrees above the horizon, the refraction of the atmoſphere occaſions it to be conſiderably coloured. The refraction of the lens acting in a contrary direction would exactly correct that colour, if the diſſipation of the rays of light were the ſame in glaſs as in air, but as it is greater in glaſs than in air, the colours occaſioned by the refraction of the atmoſphere will be rather more than corrected by thoſe occaſioned by the refraction of the lens. We may conclude this deſcription with the ſubjoined references to *fig.* 3. of *Plate* XII. which is a view of this apparatus:

" A A, the circular braſs tube which fits on to the end of the teleſcope.

" B B, the oblong concave lens, in its frame, which ſlides over the fixed convex lens.

" C, the circular ſpirit level, which ſhews when the oblong lens is in a vertical arch.

" D, the quadrant to which the ſpirit level is fixed, for ſhewing the angular elevation of the teleſcope.

" E, the milled head fixed to a pinion, by which the whole apparatus is turned round on the end of the teleſcope, in order to ſet the oblong lens in a vertical arch.

" F, another pinion for ſetting the quadrant to the angular elevation of the teleſcope. By means of theſe two pinions the air bubble muſt be brought to the middle of the level.

" *a a*, is the ſcale, with diviſions anſwering to minutes and half minutes of the refraction occaſioned by the concave lens."

The beſt portable equatorial inſtrument of the Dollonds, with a 17 inches achromatic teleſcope, is marked in their catalogue at 84*l.*; and their achromatic object-glaſs micrometer of the new conſtruction, at 21*l.*

Were we to be guided by a ſimple compariſon of this inſtrument and its refraction apparatus with Ramſden's, and to infer from thence which of the two was prior in point of time, we ſhould be induced to place this before the other for obvious reaſons, deduced from their comparative conſtructions, particularly the ſituation of the levels and refraction apparatus, and total elevation of the teleſcope, but, on minute inquiry, we found that Ramſden's was the firſt, and we can only account for the preference we are diſpoſed to give it, from the circumſtance of his having a patent, that precluded the latter, though his brother-in-law, from adopting his conſtruction. If there is any real comparative advantage in Dollond's, now that his achromatic teleſcopes are generally made, it is that which ariſes from the graduation of the latitude quadrant, and the lightneſs of the whole inſtrument; Ramſden's weighing 59 pounds, and Dollond's only 30.

Portable equatorial inſtrument by Fayrer.—We have already ſaid that Mr. Fayrer of White Lion ſtreet, Pentonville, has the poſſeſſion of a large engine for cutting clock wheels, &c. the property of his uncle Troughton, which we have deſcribed under our article Cutting-*engine* as originally made by Rehe: this artiſt, during ſome of his hours not occupied by his engine, makes mathematical and philoſophical inſtruments, and among others he has lately conſtructed a portable equatorial inſtrument for Mr. Lowe of Iſlington, which, we think, merits a place in our collection, as being not only an original one, but as poſſeſſing advantages likely to recommend it to public attention. This portable inſtrument differs from its predeceſſors chiefly in theſe reſpects; it has no azimuth circle fixed in a permanently horizontal poſition; it has its equatorial circle divided into degrees and alſo into time, with two verniers reading at oppoſite points, one vernier reads to the accuracy of 30″ of ſpace, and the other to 2″ of time; this circle has a long axis paſſing through a tube, like Troughton's large Coimbra inſtrument hereafter deſcribed, from which probably this part of the conſtruction was taken; it may, therefore, be placed in a horizontal direction by its axis being placed firmly vertical, in which ſituation it becomes an azimuth circle; the teleſcope is fixed on the end of the axis of the declination circle, which idea correſponds with, and may have been borrowed from, Nairne's conſtruction; this poſition allows any elevation of the teleſcope that may be required, and keeps the obſerver's eye at a diſtance from the other parts of the inſtrument, but injures the uniformity of the appearance of the inſtrument as a whole; the levels are applied, one on the common axis of the teleſcope and declination circle, and the other at right angles thereto, as a chord to the declination circle; and laſtly, the declination circle is complete, with oppoſite verniers reading, like the other oppoſite verniers, to an accuracy of twenty or thirty ſeconds, according to the dimenſions of the graduated circles, when nicely divided on Troughton's dividing engine. From ſuch conſtruction it is eaſy to perceive, that this little inſtrument poſſeſſes the advantage of having its teleſcope reverſed as well as its circles with reſpect to the oppoſite verniers, which property greatly enſures the accuracy of the adjuſtments. After theſe previous remarks it will ſuffice to give a brief detail of the parts of this inſtrument as repreſented in *fig.* 4. of *Plate* XI. *of Aſtronomical Inſtruments.*

A, A, A, are three adjuſtment-ſcrews for levelling the circular ſtand to which the feet are faſtened; B, B, are a pair of triangular frames fixed firmly to the ſaid circular ſtand, and ſupporting the pivots of the horizontal axis, round which the tube C, attached to the axis, moves; at the ſummit of the more viſible triangular frame B is an adjuſtable or ſliding part Y, like that of a tranſit-inſtrument, by which the teleſcope may be adjuſted into the meridian, when previouſly placed nearly ſo by the feet. The graduated circle D, which may be either an equatorial or azimuth circle, accordingly as its axis is inclined or vertical, has a ſteel axis nicely fitted to revolve in the tube C, in any poſition of this tube with reſpect to the horizon; but the double vernier bar is faſt to the inferior end of the tube, as may be ſeen in the figure: the poſterior pivot of the horizontal axis, borne by the triangular bars B, B, projects, and has firmly attached to it the quadrantal piece E, partly hidden from ſight in our view of the inſtrument; this quadrantal piece is graduated, and reads by a vernier as minutely as the other circles; it ſerves to ſet the equatorial axis parallel to the earth's axis, in which ſituation it may be clamped faſt, as well as in a vertical, or indeed any other poſition, by a clamping ſcrew out of ſight in the preſent poſition applying to the quadrantal arch; F F is the declination circle, with its horizontal axis reſting on a pair of vertical ſupports, carried by the upper end of the polar axis, that paſſes through the tube C, ſo that, when the teleſcope, attached to the axis of the declination circle, has any horizontal or rather oblique motion, the circle D moves with it, and indicates the diſtance moved along the equator, or in a circle parallel to it, when the polar axis is properly adjuſted and clamped faſt. The double vernier bar is on the poſterior plane of the declination circle, and may therefore be viewed after an obſervation without danger of altering the poſition of the teleſcope. The level on the declination axis may be conveniently adjuſted by turning the circle D half round, and by making the bubble keep the middle of the tube in both ſituations, which may be done, partly by the ſcrews A, A, A, and partly by the ſcrews of rectification of the level itſelf; and zero of the declination circle may be put to zero on the verniers when the circle D is truly placed in an horizontal poſition, in which ſituation alſo zero of the quadrant E muſt coincide with zero on its vernier. Under theſe circumſtances the levels will be competent to effect all that is required, and in the beſt way; and the inſtrument will poſſeſs all the various powers aſcribed to a portable equatorial inſtrument when converted into the other inſtruments.

Univerſal equatorial inſtrument by Mr. Ed. Troughton.— The equatorial inſtruments we have hitherto deſcribed are all, properly ſpeaking, portable, and conſequently of a ſize not profeſſing great accuracy in their readings. We now come to an inſtrument of larger dimenſions, and one having its parts ſo arranged and adjuſted, as to entitle it to rank among the firſt claſs of inſtruments employed in modern obſervatories. It is of the univerſal kind, and may be called moveable (in oppoſition to fixed) rather than portable, as it ſtands ſeven feet high, and is therefore too bulky to be carried by one man. It was finiſhed in the year 1788 for the late Mr. J. H. Magellan, and ſent by him to the univerſity of Coimbra in Portugal, where we have ſaid it has been unfortunately ſhut up in the dark. *Plate* XIV. *of Aſtronomical Inſtruments*, exhibits a perſpective drawing, ſhewing all the principal parts of this excellent inſtrument in its equatorial poſition, which we propoſe to deſcribe in the order of their aſcent from the ground.

It will not be neceſſary to give any letters of reference to this inſtrument, as it is preſumed the reader, who has made himſelf acquainted with the component parts of the preceding inſtruments, cannot be at a loſs to accompany us in our deſcription of the preſent inſtrument without the aid of alphabetical references. The baſis is of mahogany, conſiſting at the inferior part of a ſtrong tripod, and at the ſuperior of a circular table; theſe are connected by three pieces diverging from the table downwards, and connected by diagonal croſſing bars: this frame work is ſtill further united by three vertical pillars near the centre, one of which is omitted in the drawing, in order to expoſe to view a more eſſential part. Immediately above the table, and parallel to it, is a very ſtrong azimuth circle of braſs, 24 inches in diameter; this circle, however, is not in contact with the table, but reſts on its conical axis, that paſſes through a collar of braſs, attached to the centre of the table, and is ſupported on its conical point on a ſtud faſt to the centre of the tripod. This length of bearing, like that of Mr. Nairne's deſcending axis, keeps the azimuth circle ſteady in the horizontal line both in motion and at reſt, which is a circumſtance of the utmoſt importance. The tripod is furniſhed with three ſtrong feet ſcrews for the adjuſtment of the azimuth circle into a true horizontal poſition; and three handles, with each a Hook's joint, are attached reſpectively to thoſe ſcrews, that the adjuſtments may be made with the body in an upright poſition. or nearly ſo. The apparatus for quick or ſlow motion is ſcrewed faſt to the table, and clamps to the azimuth or horizontal circle. Two oppoſite verniers, reading to the accuracy of 10″, are attached to the edge of the table, but in ſuch a way that they are of ready adjuſtment to an exact biſection of the circle, in caſe the wood work of the table and frame ſhould alter its figure by warping in the leaſt degree; otherwiſe the wooden frame, as a pedeſtal, would have been objectionable. Upon the plane of the ſaid azimuth plate are erected two vertical ſupporters of frame work, ſomewhat reſembling the appearance of two chair backs; which ſupporters conſequently have a motion in azimuth whenever the circle is turned round; they are 19 inches apart from each other, and an horizontal axis of this length binds them together at their upper extremities;

the poſterior ſupporter has an adjuſtment apparatus for bringing the axis perfectly horizontal, which apparatus is hidden in the drawing behind the ſaid ſupporter. At the middle of the horizontal axis called alſo the axis of latitude, is a cubical part ſimilar to that in the axis of a tranſit inſtrument; to this the long braſs ſocket or tube, that embraces the polar ſteel axis, is made faſt, and is ſet exactly at right angles thereto by conſtruction. The polar axis, that paſſes down through this ſocket, has the equatorial or hour circle attached firmly to it, at right angles alſo by conſtruction, at its inferior end; and to its ſuperior end above the axis of latitude, is fixed a ſmall platform, of the ſhape of a parallelogram, to ſupport the ſuperſtructure not yet deſcribed. Any additional weight may be fixed to the lower end of the polar axis, that the ſuperincumbent materials may require to form an exact equipoiſe in any poſition; the ſiderial time, depending on the horary angles, is read by oppoſite verniers, fixed to the inferior end of the long polar ſocket; one of which only can be ſeen in the figure of the inſtrument, as it ſtands in the drawing: the equatorial circle is divided, ſo that a ſingle ſecond of time is diſtinctly read by the verniers; and if the application of three verniers had been thought of when this inſtrument was conſtructed, the inequality of the diviſions would have been corrected thereby ſtill more perfectly, as well as the excentricity of the circle, if any exiſts; which obſervation will equally apply to the azimuth and declination circles. Two quadrants are made faſt to the pivots of the axis of latitude, or horizontal axis already deſcribed, having their poſition juſt within the vertical ſupporters of the ſaid axis, and conſequently move with it, when it has any motion: theſe quadrants are divided, one of them agreeably to the uſual diviſions of the circle, and the other by particular deſire into 96 equal parts with its ſubdiviſions, and the two verniers are reſpectively placed on the contiguous ſupporters of the axis; the uſe of the quadrants is to fix the elevation or inclination of the polar axis agreeably to the latitude of the place of obſervation; that is, parallel to the axis of the earth; which poſition requires to be well verified when the inſtrument is uſed. Between the feet of the ſupporters, and at right angles to each other, are placed, on the plane of the azimuth circle, two nicely ground ſpirit levels, one of which is about half viſible, and the other ſtill leſs, which ſerve to place this circle perfectly horizontal in every direction, by the aid of the feet ſcrews: and near the centre of the ſame circle may be ſeen an apparatus for adjuſting and fixing the polar axis in any given degree of inclination from a horizontal to a vertical poſition, which it does with equal convenience, accuracy, and ſteadineſs: the lower end of this apparatus may be ſcrewed to any pair of the parallel holes made in the plate, farther from, or nearer to, the centre, as the quantity of inclination may require; while the upper end is attached to a broad ring embracing the ſocket of the polar axis; and about the middle is an adjuſtment ſcrew, juſt above a Hook's joint, that allows the ſcrew to act freely in any poſition of this apparatus. The ring that embraces the long ſocket of the polar axis will ſlide along it till the ſtem of the ſaid apparatus, into which the ſcrew acts, ſtands at right angles to the polar axis, in which ſituation its poſition will be firm and ſteady, as the axis can have no lateral or vibratory motion, by reaſon of its union with the axis of latitude. From this deſcription of the apparatus in queſtion it is eaſy to perceive that the nearer the polar axis approaches to a vertical ſituation, the farther from the centre of the azimuth plate muſt the fixing ſcrews be inſerted, and *vice verſâ*; alſo the lower towards the equatorial circle muſt the ſliding ring be, that embraces the ſocket; as well as the ſteadier the axis ſo fixed. Again, upon the platform on the ſuperior end of the polar axis, already noticed, are erected a ſecond pair of ſupporters, at the diſtance of 15 inches from each other at the bottom, and bound together at the ſame diſtance at top by the axis of the declination, which conſequently is 15 inches long; theſe ſupporters, which partake of any motion given to the equatorial circle, bear the declination or meridian circle, and teleſcope ſurmounted over all. At the upper end of one of theſe laſt named ſupporters is an adjuſtment for ſetting the declination axis at right angles to the polar axis, which is a very eſſential adjuſtment; the apparatus for producing quick or ſlow motion is faſt to the platform, the milled nuts of which apparatus may be ſeen under the declination circle; alſo the oppoſite verniers for reading off the angles of declination are attached to the ſaid platform, and both faces of the circle are divided, like the quadrants, one according to common uſage, and the other into 384 diviſions with their ſubdiviſions, which, at the time of the conſtruction, were conſidered by Mr. Magellan as the beſt check on the accuracy of the verniers that read off to 10″. The elevated ſituation of the teleſcope, which is $3\frac{1}{2}$ feet long, is ſufficiently explained by the drawing, where ſome of the ſupporters are ſeen attached to the declination axis, and ſome to the circle itſelf; this elevation was given, that the eye-tube might keep clear of the ſupporters and other parts of the mechaniſm, when a ſtar or planet is followed along the equator, or other circle parallel thereto; and as the declination circle is complete, the teleſcope will riſe to any degree of elevation that may be required, while the circle will meaſure that elevation. As a tangent to the upper edge of the circle, and parallel to the line of collimation of the teleſcope, is a very ſenſible ſpirit level with proper adjuſtment ſcrews: and on the upper ſide of the tube of the teleſcope are mounted two microſcopes, the uſe of which is to obſerve the coincidence of a fine plumb-line with points made on the tube, when placed in a vertical poſition for the purpoſe of levelling the declination axis; and indeed many of the adjuſtments of this inſtrument may be verified both by the plumb-line and levels. There are various eye-pieces to anſwer different purpoſes, both with and without diagonal reflectors for high altitudes, which it is not neceſſary to deſcribe here minutely, as they form no diſtinguiſhing feature of the inſtrument. Laſtly, the refraction apparatus placed at the eye end of the teleſcope, as made by Ramſden, was an appendage of this inſtrument, and by moving the adjuſtable croſs wire in the focus of the eye glaſs a quantity equal to the refraction or refraction and parallax taken together, rendered the calculations from the tables unneceſſary, by converting mechanically the apparent into the true altitude of any obſerved body. The reading of the ſubdiviſions of a circle by means of a microſcopic micrometer had not been adopted at the period this beautiful and uſeful inſtrument was conſtructed, otherwiſe its powers would have been made more extenſive than they now are by the verniers alone.

It is hardly neceſſary to add, that the powers of this univerſal inſtrument, as far as they go, may be readily and conveniently applied to almoſt all the purpoſes of practical aſtronomy, as well as of land-ſurveying and levelling; ſeeing it has all the properties aſcribed to the preceding inſtruments, but in a degree approaching nearer to perfection. This is the only inſtrument of the conſtruction here deſcribed that ever was made on ſo large a ſcale, but three or four others of an inferior ſize have ſince been made on the ſame plan; that, as portable inſtruments, can hardly be ſurpaſſed unleſs by the adoption of triple verniers, which are of recent origin.

Adjuſtments.—1. In the firſt place, the *teleſcope* muſt have its wire-plate turned round into ſuch a poſition, that the middle vertical wire will coincide with a diſtant mark throughout the whole field of view, as the teleſcope is elevated or depreſſed, and then the object-glaſs muſt be ſlided in or out, till a ſtar of the ſecond magnitude is ſeen as diſtinctly as poſſible, to prevent parallax at the wires.

2. In the next place, make the *azimuth circle horizontal* by means of two levels, adjuſting one half of the error, produced by turning the circle half round, by means of the feet-ſcrews, and the other half by the levels, as with the preceding inſtruments.

3. Make the *polar axis perpendicular;* clamp it nearly ſo, and turn the declination circle round till the bubble ſtands in the middle of its level, now turn the upper part half round on the polar axis, and, if there is an error, correct one-half of it by the apparatus acting on the polar axis, at the azimuth plate, and the other half by turning round the declination axis by the ſlow motion. When the error has diſappeared by a repetition of this proceſs, turn the declination circle round the polar axis juſt ſix hours, and bring the bubble to the middle by the adjuſtment at the top of one of the ſupporters of the latitude axis: when this is done the azimuth and equatorial circles will be parallel to each other, and their axes perpendicular to the horizon; and, of courſe, the level near the teleſcope will keep its bubble at the middle, as well as the other levels, while either or both of theſe circles revolve. Here the verniers of the latitude-quadrants may be ſet to their reſpective zeros.

4. The declination axis muſt be ſet *level*, or at right angles to the polar axis. In order to do this, ſet the teleſcope perpendicular by fixing the declination circle with its vernier at 90°, and put on the plumb-line; by the motion of one of the points, which is *adjuſtable*, and alſo by the proper motion of the plumb-line; make the latter biſect both the points under the microſcopes; reverſe now the teleſcope by turning the declination circle to the oppoſite 90°, ſuſpend the plumb-line from the contrary end of the teleſcope, and by the proper motion of the line make it biſect the *fixed* point; then half the error that appears at the adjuſtable point muſt be corrected by that adjuſtment, and the other half by that at the top of the ſupporter of the declination axis.

5. The line of collimation of the teleſcope muſt next be adjuſted, both as it regards the right aſcenſion and declination. In order to do this, let the upper end of the polar axis, and the object-end of the teleſcope, be pointed to ſome fixed object a little above the horizon, the declination circle being firſt put with 90° to the zero of its vernier, the hour index placed at XII, and the teleſcope above the polar axis; bring now the centre of the croſs-wires to the object fixed on, by raiſing or lowering the polar axis in conjunction with a motion in azimuth, and read off the degrees, minutes, and ſeconds ſhewn by the verniers of the azimuth circle and quadrants reſpectively; in the next place, ſet the polar axis nearly vertical, and place the hour circle at the oppoſite XII, and point the polar axis, as before, to the ſaid fixed object, the teleſcope being now below it; move the inſtrument as before, by a compound motion of the polar axis and azimuth circle till the interſection of the middle wires coincides with the object before fixed on and uſed, and read off, as before, the degrees, minutes, and ſeconds both on the azimuth circle and quadrants: in this ſituation of things, ſet the azimuth circle to the *mean* of the two obſerved azimuths by taking half their ſum, and alſo the polar axis to the *mean* of the two obſerved altitudes or inclinations of the polar axis; in this poſition of the inſtrument, let the teleſcope be carefully moved by altering the ſcrews that faſten it to the circle, until the vertical central wire coincides with the original object, and the adjuſtment for right aſcenſion is finiſhed. Again, move the teleſcope, by altering it in declination, till the horizontal wire cuts the ſame object, and adjuſt the verniers of the declination-circle to the points 90° and 96 parts reſpectively on its oppoſite planes. If, however, the object is not a very diſtant one, the above directed adjuſtment in declination will not be quite correct, becauſe the teleſcope ſtands *higher*, when *above* the pole than it is *below;* conſequently, when this adjuſtment is made by means of a near object, two marks ſhould be uſed on that object, the diſtance between which muſt be double the meaſure from the centre of the declination axis, to the line of collimation of the teleſcope; otherwiſe a ſmall angle will be formed at the object, by the two lines of ſight, which angle will be ſubtended by the double diſtance in queſtion; but when the object is at an infinite diſtance this ſmall ſubtenſe is reduced in effect to nothing, and the ſame mark therefore will do in both the poſitions of the teleſcope.

6. To adjuſt the hour index let the point 90° of the azimuth circle be turned to an object of ſmall altitude; let the polar axis be made horizontal; and the teleſcope be ſet to 0° of declination: in this poſition the hour circle becomes vertical, and the altitude of the object may be taken by it, which muſt be read off in time from VI hours: turn now the inſtrument half round in azimuth, and make the teleſcope look towards the object by turning round the polar axis; take another altitude in this poſition, and read off what is indicated from the oppoſite VI hours, and the mean of theſe two altitudes is the exact place where the adjuſtable index muſt have its zero placed to be in its true poſition.

The apparatus for correcting the horary angle on account of refraction conſiſts of a ſmall quadrant and level for taking altitudes, which are moveable round the axis of viſion, and therefore determine very readily the elevation of the teleſcope in any given poſition; alſo the eye-piece and wires of the teleſcope being moveable by means of a nice micrometer ſcrew, may be ſet with great accuracy to the refraction correſponding to the altitude of the obſerved body as determined by the ſmall quadrant and level.

The chief advantages reſulting from the conſtruction of the equatorial inſtrument juſt deſcribed, are, firſt, that it affords a firm ſupport to a very long, and, therefore, powerful teleſcope; and, ſecondly, that the great range of polar diſtance beyond 90° of declination renders an obſervation with the teleſcope below the polar axis unneceſſary.

As the rules we gave for uſing Ramſden's portable inſtrument, as extracted from profeſſor Vince's treatiſe, are not exemplified by actual obſervations, and as rules, however plain, are not always underſtood without the illuſtration of appropriate examples, we cannot finiſh our account of the preſent inſtrument better than by ſubjoining to the rules given by the Hon. Mr. M'Kenzie his examples given at full length, when adapted to our purpoſe, by which the reader will be led to have an idea of the practical application of the obſervations to the various purpoſes of aſtronomy. The rules were originally written as directions for the uſe of Ramſden's inſtrument, but after our account of the adjuſtments,

ments, they are equally applicable to the inſtrument under our immediate conſideration.

Obſervation 1. *To find the latitude of the place by the ſun, or any known fixed ſtar.*—The inſtrument being perfectly adjuſted in all its parts according to the directions given,—

Make the polar axis perpendicular to the horizon, and when the ſun approaches his meridian altitude, elevate the teleſcope to that altitude, and adjuſt the refraction apparatus as above directed: then follow the ſun by moving both the equatorial and declination circles (if neceſſary), and keeping the refraction piece always adjuſted till he is at his greateſt altitude; the vernier of the declination circle will then give you his meridian altitude; from which ſubtract his declination, if it be north, or add it if it be ſouth, the remainder if north, and the ſum if ſouth, is the height of the equator, that is, the complement of your latitude, which being ſubtracted from 90°, gives your latitude.

Example.

Sun's declination ſuppoſed - -	6°	57′	37″	North.
Meridian altitude of his centre obſerved	45	6	29	
Subtract his declination -	6	57	37	
Height of the equator or co-latitude	38	8	52	
Which ſubtracted from -	90	0	0	
Gives your latitude -	51	51	8	

If inſtead of obſerving the altitude of the centre, you obſerve that of the upper or lower limb of the ſun, you muſt allow for the ſemi-diameter of the ſun, which allowance you find in the Nautical Almanac. Alſo, if the refraction apparatus were not uſed, the tables for refraction and parallax in altitude muſt be uſed to reduce the apparent to the true altitude.

Obſervation 2. *To find the meridian by one obſervation only.*—Elevate the equatorial (or hour) circle to the co-latitude of the place, ſet the declination circle to the ſun's declination for the day and hour required; and adjuſt the refraction apparatus, then move the azimuth and hour circles both at the ſame time (either in the ſame or a contrary direction) till you bring the centre of the moveable wires (the vertical being truly perpendicular) exactly to cover the apparent centre of the ſun; that done, the centre of the fixed wires will be in the true centre of the ſun, the index of the hour circle will then give the apparent or ſolar time at the inſtant of obſervation. Thus you get the time though the ſun be at a diſtance from the meridian. Then turn the hour circle till the index points preciſely at 12 o'clock, and lower the teleſcope to the horizon to obſerve ſome mark in the centre of the teleſcope, and that is your meridian found by one obſervation only.

The beſt time for finding the meridian is, when the ſun is three hours diſtant from the meridian on either ſide of it.

Obſerve, that when you have once a true meridian fixed, you need make no uſe of the refraction apparatus in any obſervation, except to ſet one of the moveable wires perpendicular.

The meridian and ſolar time may be found in like manner by a fixed ſtar, whoſe declination and right aſcenſion are known.

Obſervation 3. *To obſerve a ſtar or planet in broad daylight, at any time when it is above the horizon.*—The table of right aſcenſions, declinations, &c. of Dr. Maſkelyne's 36 principal fixed ſtars, under the articles CHRONOMETER and DECLINATION, gives you the times of their tranſits over the meridian in ſiderial time.

Elevate the equatorial circle to the co-latitude of the place, and ſet the vernier of the declination-circle to the ſtar's declination, then adjuſt the refraction piece; look into the table for the time of its meridian tranſit or right aſcenſion; then take the time of the ſaid tranſit from the time of your obſervation as given by the ſiderial clock, borrowing 24 hours if neceſſary; this difference is the hour to which you muſt ſet the hour index of the equatorial circle, and the ſtar will then appear in the teleſcope.

Example 1.—Let it be required to place the teleſcope of the equatorial inſtrument to obſerve Capella on Sept. 30th 1809, exactly at $9^{h}\ 0^{m}\ 0^{s}$ by a ſiderial clock well regulated?

Declin. of Capella from Tab. III. under CHRONOMETER, 1806 -	45°	47′	5.″88	North.
$3\frac{3}{4}$ years of annual variation add from ditto - - -	0	0	17.14	
True declination -	45	47	23.02	North.
Right aſcenſion or ſiderial time of tranſit from ditto, 1806 -	5^{h}	2^{m}	22.ˢ62	
$3\frac{3}{4}$ years annual variation add -	0	0	16.55	
True time of tranſit -	5	2	39.17	
Which ſubtract from ſiderial time of obſervation - - -	9	0	00.00	
And there remains the interval ſince the tranſit for the index to be put to	3	57	20.83	

Note, if the clock ſhews ſolar time, it muſt be converted into ſiderial time by problem VI. under our article CHRONOMETER, and then the work may be done as here directed.

Example 2.—Let it be required to find Arcturus on April 1ſt, 1810, when the ſiderial time is $10^{h}\ 30^{m}$?

Declin. of Arcturus 1806 -	20°	11′	59.″41	North.
$4\frac{1}{4}$ years annual variation ſubtract	0	1	19.85	
True declination -	20	10	39.56	North.
Right aſcenſion or ſiderial time of tranſit - - -	14^{h}	6^{m}	48.ˢ83	
$4\frac{1}{4}$ years annual variation add -	0	0	11.59	
True time of tranſit -	14	7	0.42	
Which take from the time of obſervation, borrowing 24^{h} - -	34	30	0.00	
The remainder is the place of the index	20	22	59.58	

In this obſervation Mr. M‘Kenzie uſed a table of meridian paſſages given in ſolar time, which required the acceleration of ſiderial or ſolar time to be uſed; but as the principal catalogues give the paſſages in ſiderial time, we have adapted his rule thereto.

Obſervation 4. *To find the right aſcenſion and declination of a planet, comet, or fixed ſtar.*—The equatorial circle being elevated, as before, to the complement of the latitude of the place, move the declination and equatorial circles till the planet or comet is in, or near the centre of the field of the teleſcope, then adjuſt the refraction piece, and bring the centre of the moveable wires to cover the planet, the vernier of the declination circle will then give you the declination of the planet, and the vernier of the equatorial circle will give you the hour of the planet, &c.; then your regulator or clock will give you the ſun's time or hour of the day. Take the difference between the ſun's time and the planet's time; and if the planet's time be leſs than the ſun's time, add that difference to the ſun's right aſcenſion at the time of obſervation, (which you find in the Nautical Almanac,) the ſum (rejecting 24 hours, if it exceeds that number) is the right aſcenſion of the planet, &c. Again, if the planet's time exceeds the ſun's time, ſubtract the difference from the ſun's right aſcenſion; the remainder (adding 24 hours to the ſun's right aſcenſion, if neceſſary,) is the right aſcenſion of the planet, &c.

Example 1.

Obſerved a ſtar whoſe time by the equatorial circle is - -	2^{h}	18^{m}	3'	P.M.
Sun's time as given by the regulator, *viz.* - - - -	9	44	40	P.M.
Difference between the two	7	26	37	
As the ſtar's time is leſs than the ſun's, add that difference to the ſun's right aſcenſion - - -	20	57	9	
Reject 24 hours from	28	23	46	
Right aſcenſion of the ſtar is	4	23	46	

Its declination (by the vernier of the declination circle) is 16° 2′ 50″ north.

Example 2.

Obſerved a ſtar whoſe time by the equatorial circle is 10^{h} A.M. (that is, aſtronomically) - - -	22^{h}	0^{m}	0^{s}
Sun's time as given by the regulator, *viz.* 5° 55′ 4″ A.M. (that is, aſtronomically) - - -	17	55	4
Difference between the two	4	4	56
As the ſtar's time exceeds the ſun's, ſubtract that difference from the ſun's right aſcenſion - -	10	38	58
Remains the right aſcenſion of the ſtar	6	34	2

Its declination (by the vernier of the declination circle) is 16° 25′ 1″ ſouth.

Obſervation 4. To find the longitude at land by the right aſcenſion of the moon.

Obſerved the centre of the moon on the moveable wire ſet vertical, either in or out of the meridian; time given by the equatorial or hour circle, ſuppoſe - - -	2^{h}	28′	2″
Sun's apparent time by the regulator	6	0	0
Difference between thoſe times	3	31	58
Add that difference to the ſun's right aſcenſion at 6 hours (becauſe the moon's time is leſs than the ſun's time, for had it been greater, the difference muſt have been ſubtracted)	8	25	27
And you have the moon's right aſcenſion at the place of obſervation at 6 hours - - - -	11	57	25

Another method of making the above obſervation.—The centre of the moon being obſerved in the ſame manner at ſix hours P.M. as before directed, let the inſtrument remain in the ſame poſition it was in (only altering the declination) till a known ſtar comes to the vertical wire, which will happen (ſuppoſe) in one hour after, *viz.* at 7 hours, then ſubtract that one hour of difference in time of tranſits, with the addition of 9″ 86^{dec} for the acceleration correſponding to one hour, that is, ſubtract 1^{h} 0′ 9″ 86^{dec} from the AR of the ſtar, ſuppoſed to be 12^{h} 57′ 35″, the remainder is the moon's AR at ſix hours P.M. at the place of obſervation.

Star's right aſcenſion - - -	12^{h}	57′	35″
Difference in ſiderial time, (ſee CHRONOMETER, Tab. I.) - - - - -	1	0	9.86
Moon's right aſcenſion at 6 hours P. M. at the place of obſervation. - - -	11	57	25.14

Then find, by the Nautical Almanac, at what time at Greenwich the moon has the ſame right aſcenſion as that now obſerved.

Moon's right aſcenſion at Greenwich at noon is	11^{h}	43′	20″
Ditto at midnight - - -	12	10	36
Difference in thoſe 12 hours -	0	27	16

Moon's right aſcenſion at Greenwich at noon	11^{h}	43′	20′
Moon's right aſcenſion at 6 hours, at the place of obſervation - - - - - - -	11	57	25
Difference between them	0	14	5

Proportion for finding the time at Greenwich.

As 27^{m} 16^{s} : 14^{m} 5^{s} : : 12^{h} : 6^{h} 12^{m} 0′

So that the time at Greenwich, when the moon has 11^{h} 57′ 25″ of right aſcenſion, is 6^{h} 12^{m} 0,′ that is, 12^{m} later than at the place of obſervation, which is therefore 12^{m} of longitude weſt from Greenwich.

Sir George Shuckburgh's fixed equatorial inſtrument.—A B, C D, E F, G H, (*Plate* XV. *of Aſtronomical Inſtruments,*) are four columns, ſays ſir George Shuckburgh, compoſed of hollow braſs tubes $3\frac{1}{2}$ inches in diameter, and five feet ten inches long; theſe, with two others, one of which appears in part at I K, and the other partially hidden behind E F, are firmly fixed, at their upper ends, to a circle of bell metal B D F H, and, at their lower end, to an inverted truncated hollow cone, L L L, of braſs, in height two feet, and in diameter, at the baſe A G, one foot nine inches. The croſs pieces, or tubes P, P, as likewiſe O, O, and O, O, ſerve to connect the columns more ſtrongly together, and prevent their bending. Theſe ſeveral parts conſtitute the principal axis of the inſtrument, the lower end of which terminates in a ſteel point or cone, reſting in a hollow conoid of bell metal, in ſuch manner that the apex of the former does not reach to the bottom of the latter, but the place of bearing, or of friction, is (it may be) about two tenths of an inch from the extremity of the cone; the other end of this axis finiſhes in a cylindrical pivot N, of about $1\frac{1}{4}$ inch long, and one inch in diameter, turning in a Y of bell metal. The entire length of this axis is eight feet four inches, the lower end being ſupported by an iron frame 3, 4, 5, 6, 7, 8, which is firmly fixed below the floor, into brick-work, and by means of two iron bars, one of which is ſeen at 28, and the other on the oppoſite ſide, not viſible in the drawing, is kept ſecure from any motion, eaſtward or weſtward; the lower part of this frame, to about one foot high, is incloſed by a mahogany box or caſe 9, 10, the top of which is entirely covered up, and ſerves as a die or baſe to this end of the inſtrument. The other extremity of this long axis, *viz.* the pivot N, reſts upon the ſtrong iron ſupport 29, 30, 31, ſtanding 10 feet above the floor, made of maſſive pieces of caſt iron, $2\frac{1}{2}$ inches wide, and $\frac{1}{2}$ an inch thick, and held firmly by bolts and nuts as in the figure: 32, and 33, are the places where two iron bars, nearly at right angles to each other, and at $\frac{1}{2}$ right angles to the meridian, are ſcrewed, to connect this upright ſupport with the walls of the building, and going through the bricks, are held faſt by iron collars and nuts on the outſide of the wall; theſe bars, or braces, not in the figure, reſiſt any tendency from the weight or preſſure of the inſtrument, to puſh the ſupporter 29, 30, and 31, out of its upright poſition; and being at right angles to each other, ſerve to keep it ſteady with reſpect to any lateral force that may accidentally be applied. The lower part is continued below the floor, and firmly fixed with mortar and lead into the brick work of an arch. The bottom is ſhut up in a box or plinth of mahogany, 34, 35, as has been mentioned in the deſcription of the frame ſupporting the other end of the axis at 9, 10. Near the lower end of the principal axis L N, are inſerted 10 concentric braſs cones, or radii, *a a*, *b b*, *c c*, *d d*, *e e*, carrying on their extremities a graduated braſs circle, of $49\frac{1}{2}$ inches dimeter, at right angles to the principal axis already deſcribed; this circle has two ſets of diviſions, one of points, and one of lines, each into degrees, and every ten minutes, and the intermediate minutes and ſeconds are read off by the microſcopes W and X, with a moveable wire, and micrometer ſcrew, ſuch as has been deſcribed in general Roy's account of his inſtrument for meaſuring horizontal angles. (See Philoſophical Tranſactions, vol. lxxx. p. 145.) The circle juſt mentioned, is incloſed by a circular frame, or rail of mahogany, 14, 15, which is ſupported by ten baluſters, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, (17 and 24 being concealed) and ſerves to protect the braſs circle from any accidental injury in paſſing by it, without depriving it of expoſure to the general temperature of the room. It at the ſame time affords means of ſupport to a ſmall lamp, 13, which, by reflection from the perforated ſpeculum at the bottom of the microſcopes, to be ſeen in that marked X, throws light upon the diviſions by night: 26, 26, and 27, are iron rods that, by being attached to the wooden caſe, 9, 10, give ſteadineſs to the upright baluſters, and the circular frame that they ſupport: 1 and 2 are large ſtout braſs cones firmly fixed into the frame, 3, 4, 5, 6, 7, 8, before mentioned, and whoſe uſe is to carry the microſcopes W, X. Any degree of pliancy or flexure in theſe cones would be readily diſcernible in the microſcopes, and extremely detrimental to the obſervations; they are therefore made as ſtiff as poſſible: ∂ is a plane forming the upper ſide of the frame, 3, 4, 5, 6, &c. and conſiſting of three plates, two moveable in grooves; and one fixed, furniſhed with ſuitable ſcrews, one giving the extremity of the axis a motion upward or downward, and the other a motion to the right or left. This latter is procured by a rod paſſing through the cone. 2, one end ſcrewing into the plate below L, near the centre, and the other turned by an occaſional handle fixed on, near X, the former motion, *viz.* of elevating or depreſſing the axis, is procured by a handle fixed on to a ſcrew near ε: Q R is another circle of the ſame dimenſions with the former, graduated in the ſame manner, and held together by eight conical radii, *f f*, *g g*, *h h*, *i i*, firmly ſcrewed to a circular centre-piece, which ſerves as a baſe to a large conical axis, two feet three inches long, one ſide of which is ſeen at U, and its exterior extremity near V, with its ſliding plate and ſcrews for adjuſtment. Cloſe behind the graduated circle, and at right angles to this axis paſſing through it, lies the teleſcope T S, $5\frac{1}{2}$ feet long. This circle is likewiſe furniſhed with two microſcopes and micrometers, as in the equatorial circle, one of which is ſeen at full length at Y, and Z, the eye-tube being at Y, and the object-glaſs, with the perforated ſpeculum, to throw light at Z; the other microſcope, on the oppoſite ſide of the circle, is not ſo prominent in the drawing, being ſomewhat fore-ſhortened at Z. Near T, α, α, α, α, α, α, is an hexagonal lozenge, compoſed of ſix braſs rulers, firmly fixed to the columns A, B, and E, F, and ſupporting the lower end of the microſcopes, as the pieces β β, β β, in like manner ſuſtain the upper end. By theſe means, the wire in the field of the microſcopes becomes a fixed immoveable index, and after proper adjuſtment, an exact diameter of the circle, whilſt the teleſcope, together with the circle, turns round the conical axis beforementioned. At P is a ſpirit level, paſſing through the centre plate of the conical axis at right angles to the teleſcope, ſupported by a cock at each end, one of which appears at *k*; this cock is placed on the cone U; and by means of a ſmall-toothed wheel and pinion, the level is made to revolve round its own axis, ſo that the ſame ſide of the level may readily be brought uppermoſt, whatever poſition the circle be put into; it is alſo furniſhed with all neceſſary adjuſting ſcrews. It will readily be ſeen, that a teleſcope thus fitted up, will have all the properties of a tranſit inſtrument, while the graduated circle will poſſeſs thoſe of a meridian quadrant. For this purpoſe *l m* is a ſtout braſs tube, incloſing a ſtiff iron rod, turning upon two fine ſteel points, adjuſted by proper ſcrews, parallel to the line of ſight of the teleſcope: this rod is attached to a ſpirit level of great ſenſibility, lying below it, which, with the rod, turns round upon the ſteel points juſt mentioned, and is in fact a hanging level of the beſt conſtruction. At the eye-end of the teleſcope S is a peculiar apparatus, to correct the effects of refraction and parallax, when an obſervation is made out of the meridian: it is compoſed of two levels, a ſmall quadrant of altitude *n o*, and a ſemicircle divided with its vernier to every 5′ on the breech plate of the teleſcope, the exterior eye-tube having a circular motion by a wheel and pinion at *o*, independent of the tube that carries the croſs wires; by this means the angle of the horary and vertical circles may at any time be found, together with the altitude of the object, and then by the reſolution of two right-angled triangles the refraction and parallax in right aſcenſion and declination will be obtained: *t*, *u*, are two handles to a Hook's joint at *x x*, which turning an endleſs ſcrew at *w w*, give a gradual motion to the teleſcope in right aſcenſion or declination; and this motion can at any time be reſtrained by a clamp at *q*: 11, 12, (the latter not ſeen,) are two ſupporters to the clamp and endleſs ſcrew. The handles *t*, *u*, are hung on to any part of the inſtrument by means of the line and wire *v*, *v*, and are thus kept within the obſerver's reach. Near *r* and *s* are two microſcopes, placed on oppoſite ſides of the circle Q R, and at right angles to the line of ſight of the teleſcope, but are hidden by the columns in our figure; they are of uſe only when the plumb-line, ſuſpended from the roof of the obſervatory, is uſed in preference to the level *l m* above deſcribed, either for adjuſting the inſtrument, or obſerving a meridian altitude, in which caſe the line muſt biſect the centres of both microſcopes: *y*, and *z*, are thin perforated braſs plates, attached to the cover that goes on the object-glaſs, and by occaſionally turning them over it, change the aperture to $\frac{1}{2}$ or $\frac{1}{4}$. The croſs wires, of which there are three vertical and one horizontal, within the eye-tube S, have all the requiſite adjuſtments by ſcrews, &c. as in a common tranſit inſtrument, and are enlightened at night by a lamp fixed near to one end of the declination axis U, *viz.* that oppoſite the end V ; but this part of the apparatus is hidden behind the axis and the teleſcope, except the weight *i*, which is a counterpoiſe. This lamp throws a light through the conical axis, which is perforated at that end on purpoſe, on a ſpeculum in the centre of the teleſcope, placed at $\frac{1}{2}$ right angles to the axis of the object-glaſs, and from thence reflected to the croſs wires. This ſpeculum, which is an elliptical diaphragm, is perforated to permit all the rays from the object-glaſs to paſs unobſtructed to the eye. The contrivance has been mentioned by Mr. Vince (Practical Aſtronomy, p. 80.) From what has been already deſcribed, it muſt now be evident that if the principal, or polar axis, as it has been called, L N, be elevated to the latitude, and adjuſted to the meridian of the place, if the line of ſight of the teleſcope be at right angles to the axis V U, and this latter at right angles to the polar axis L N, the braſs circle 14 and 15 will correſpond with the equator in the heavens, and the circle Q R will become an horary circle ; that is, if the centre of the wires in the field of the teleſcope be directed to any celeſtial object, on Q R will be had its declination, and on 14 and 15 its diſtance from the meridian, from whence, by knowing the hour, the right aſcenſion will be obtained, and conſequently its true place in the heavens.

Beſides the preceding parts of this expenſive inſtrument, there are ſome neceſſary appendages, as a ſtool marked 36, and ſome others deſcribed in the original account, with references to the accompanying plates, a minute detail of all which would lengthen this article too much ; we will therefore briefly enumerate them, and refer the more curious reader to the Tranſactions themſelves for the particulars. The appendages are, 1ſt, a lamp to illuminate the croſs-wires ; 2dly, the refraction-piece hereafter deſcribed ; 3dly, the plumb-line ; 4thly, the moveable roof of the obſervatory ; 5thly, a regulator or ſiderial clock which indicates degrees, minutes, and ſeconds of ſpace on the equator ; and, 6thly, the meridian mark, conſiſting of a ſmall adjuſtable light-houſe, placed on a brick pier at the diſtance of 2970 feet, which can be ſeen as well by night as day.

After a very rigorous examination of the two divided circles of this inſtrument, it ſeems that the greateſt error, including both the inequalities of the diviſions and the excentricity, never amounts to more than 2″ in either of them, and the author calculates that an obſervation of right aſcenſion, taken *out of* the meridian, may be depended on to the accuracy of 5″, allowing an error of 2″ for counting the beat of the clock, 1″ for the deviation of the meridian mark, and $\frac{1}{2}''$ for the error in reading the microſcope ; but that the error in polar diſtance may amount to 7″, including all the errors of the inſtrument, of the adjuſtments, and of the readings. This inſtrument, it will have been obſerved, has no azimuth circle, like moſt of the portable inſtruments, but if its axis were fixed perfectly vertical, its equatorial circle would then become an azimuth circle, and the inſtrument altogether would greatly reſemble Piazzi's great circular inſtrument made by Ramſden. From what we apprehend alſo from ſir George Shuckburgh's account of the variableneſs of the errors of adjuſtment, in different degrees of temperature, we are diſpoſed to attribute much of the imperfection of this inſtrument, in this reſpect, to the metallic ſupport of the upper pivot of the polar axis, which ſupport muſt naturally elongate and contract its dimenſions alternately, by changes of temperature ; and as it is compoſed of various parts differently placed, it affords no data for aſcertaining by calculation either the quantity or direction of deviation from the truth. Before we proceed to the adjuſtments of this inſtrument, it may be proper to deſcribe the refraction apparatus which is attached to it, and which is neceſſary to be underſtood in uſing the appended tables. *Fig.* 2. of *Plate* XI. exhibits a perſpective view of this apparatus on a larger ſcale than is exhibited in *fig.* 1. where "A B is a portion of the teleſcope ; C the eye-tube ; *a b c* a divided ſemicircle, *d* its vernier fixed to A B, ſhewing the angle of the horary and vertical circles ; *e* a ſmall ſpirit-level, attached to the plate on which this ſemicircle is engraved, and moving with it by means of the ſcrew *f*, which turns a pinion, that works in a toothed wheel, that turns the whole plate, together with the exterior eye-tube round its centre, but without moving the tube that carries the croſs-wires. From hence it may be underſtood, that by turning the ſcrew *f* till the level *e* ſtands true, the index *d*, which repreſents a point in the horary circle, will mark how much the diviſion zero, which repreſents the vertical, is inclined thereto : *l k* is a ſmall quadrant of altitude, that, by means of the level *g*, and ſcrew and pinion *h*, turning on a centre at *m*, gives the elevation above the horizon of any object in the field of the teleſcope : *i* is a ſmall aperture through which a key is fixed on, to give a lateral motion to the wires to adjuſt them ; and near *f* is another ſcrew, to adjuſt them parallel to the equator and declination-circle."

This apparatus, it will be ſeen, has not the refraction-circle, or micrometer and divided nut, to elevate or depreſs the horizontal wire, a quantity correſponding to the data thereby determined, in order to convert the apparent to the true place of a heavenly body ; it therefore indiſpenſably requires the aid of ſuch tables as we have ſubjoined to our preſent article ; but Ramſden's portable inſtrument deſcribed by the Hon. S. M'Kenzie, and by profeſſor Vince, whoſe accounts we have adopted, has the addition of the micrometer ſeen in miniature at P, in the figure of that inſtrument. To that inſtrument, therefore, as well as to Dollond's, the tables are otherwiſe unneceſſary, than as they ſerve as a check on the accuracy of the mechanical contrivances in queſtion.

Adjuſtments.— The three principal adjuſtments, according to ſir George Shuckburgh's account, are, 1ſt, to adjuſt the level P *k* parallel to the declination axis U V ; 2dly, to adjuſt this axis at right angles to the line of collimation of the teleſcope ; and, 3dly, to make this axis at right angles to the polar axis. The polar axis is placed nearly in the meridian, by means of a meridian mark previouſly verified, and elevated pretty nearly to the latitude of the place. This is to be done more accurately afterwards, by the ſliding plates and ſcrews at the bottom of the polar axis. The axis of the declination-circle is then brought nearly horizontal, by its proper level, *viz.* is turned round about the polar axis, till the bubble of the level ſtands true between the indexes ; the inſtrument is then turned half round about the polar axis, = 180°, ſhewn by the microſcope W. If the bubble then ſtand true it requires no correction, but if it do not, correct half the error, by moving the equatorial circle by its handle *t*, and the other half by the (inviſible) capſtan ſcrew, which we will call *a*, or end-ſcrew ; then turn the inſtrument back again to its firſt poſition, and ſee if the level ſtands true ; if not, repeat this operation till it does, correcting one half of the error by the equatorial handle, and the other half by the ſcrew *a*. The declination-axis will then be parallel to the level, and both of them to the horizon. It muſt be remarked that in this operation it will be neceſſary to move the declination-circle round its own axis a little, in order to bring the ſame ſide of the level uppermoſt; but this in no degree affects the reſult, for the imaginary line, round which this axis revolves, is what is meant all along by the axis, and is the line to which the parallelifm of the level is referred.

The declination axis remaining in an horizontal poſition, with the level above the axis, as in the *fig.* turn the declination-circle 180°, *viz.* till the level become below the axis; then, by means of the pinion for this purpoſe, reſtore the tube of the level to an upright poſition, and ſee if the bubble ſtand true; if not, correct $\frac{1}{2}$ the error by the ſide ſcrew, and the other $\frac{1}{2}$ by *a*, the end ſcrew. Now turn the declination-circle 90° each way from its laſt ſituation, and repeat the examination of the bubble, and correct as before, $\frac{1}{2}$ by the ſide ſcrew, at the oppoſite end of the tube, at right angles to the other ſide ſcrew; and $\frac{1}{2}$ by the end ſcrew, near the ſide ſcrew in queſtion; and if after all theſe corrections in every part of an entire revolution of the declination-circle round its axis, and of the level round its axis, the bubble ſtand true, it follows that the axis of the declination-circle, and of the level, are in every direction parallel to each other, both of them to the tangent of curvature, in the middle of the level, and all three to the horizon. This adjuſtment is therefore complete.

It remains to be ſeen whether the line of ſight of the teleſcope be at right angles to the declination-axis, and the latter to the polar axis.

Take the error of the collimation of the teleſcope in right aſcenſion, by a ſtar in the equator, *viz.* let the tranſit of a ſtar on the equator over the aſſumed meridian be obſerved with the declination-circle turned towards the eaſt, and alſo towards the weſt. If there be any difference in theſe obſervations, it will denote double the error of collimation in right aſcenſion, and half of it will be the deviation of the line of ſight from a line at right angles, to the axis of the declination-circle, and is correſpondent to a ſimilar adjuſtment of a tranſit inſtrument. The amount of this error being thus aſcertained, let it be corrected by the ſcrews, at the eye-end of the teleſcope, that move the wires to the eaſt and weſt. The declination-axis, by means of its level being reſtored to an horizontal poſition, let the centre wire of the teleſcope, (by which is always underſtood the line of collimation,) be brought to biſect the meridian mark, by means of the ſliding plate, and adjuſting ſcrew, below the polar axis; the teleſcope will then become a complete tranſit inſtrument; for, by the firſt operation, the declination axis is made parallel to the level and its axis, and both to the horizon; by the ſecond, the line of ſight is put at right angles to this axis; and, thirdly, it is adjuſted to the meridian.

Now, let the error of collimation in right aſcenſion in the ſame manner be obſerved with any ſtar out of the equator, by a circumpolar ſtar, (the nearer the pole the better,) ſuppoſe the pole ſtar. If any difference in minutes and ſeconds of a great circle, as aſcertained by the micrometer, ſhould be noticed in its paſſage with the circle eaſt or weſt, halve that difference, and it will be equal to the angle that the plane of the declination circle makes with the polar axis, if the obſerved ſtar were actually in the pole; if not, divide it by the ſine of its declination, and the true angle of the plane of this circle, (or of the line of collimation,) with the polar axis will be had. Again, if this operation be repeated with any other ſtars, and the error ſo found be divided by the ſine of their declination, the error of the plane of the declination circle at the pole, *viz.* its greateſt error, or angle with the polar axis, will be had. And note, if theſe obſervations are made with ſtars on each ſide of the equator, theſe quantities will be had in oppoſite directions. Finally, the ſame may be done by two land objects, one to the north, and the other to the ſouth, the north and ſouth meridian marks, for inſtance, proper conſideration being had to their declination; by this means the error will be thrown in contrary ſenſes or doubled, and from a variety of ſuch reſults a very correct mean quantity may ultimately be deduced; and when found muſt be corrected by the ſcrews at one end of the declination axis.

It has now been ſeen, that, 1ſt, the level and its axis are parallel to the axis of the declination circle: 2dly, the line of ſight is at right angles to this axis, and parallel to the polar axis; and, conſequently, the declination axis is at right angles to the polar axis: 3dly, the polar axis parallel to that of the earth. Theſe are the chief requiſites in the adjuſtment of this inſtrument. Thoſe that remain are ſecondary, and we ſhall take them in the following order: 1ſt, the adjuſtment of the croſs wires to the focus of the teleſcope: 2dly, the hanging level: 3dly, the line of collimation north and ſouth, as well as eaſtward and weſtward: 4thly, the index wires in the microſcopes: 5thly, the refraction apparatus: and, 6thly, the power and ſcale of the microſcopes.

Firſt, *the croſs wires.* Let the eye-tube be adjuſted to diſtinct viſion for parallel rays by ſome diſtant object, ſuch as Jupiter, Saturn, or Venus, by day-light; that done, obſerve, while one limb of either of theſe planets appears running along the equatorial wire, whether any motion of the eye, upwards or downwards before the eye-glaſs, alters the relative place of the image and the wire; if a motion of the eye upwards moves the planet in the *ſame* direction, the wires are too near the eye-glaſs, and muſt be puſhed in; and *vice verſâ*, till the image becomes fixed upon the wire, whatever be the motion of the eye. When this point is obtained, the eye ſtop, with its wires, muſt then be fixed, for that is their true place, *viz.* the correct focal point of the object-glaſs; and whatever indiſtinctneſs may be found from the diverſity of eyes of different obſervers, muſt be corrected by the motion of the eye-glaſs only. Another point to be ſecured is the permanency, as far as may be, in the poſition of the object-glaſs; for if this be not correctly centered, which is very rarely the caſe, and, indeed, never to be expected, that is, if its axis be not concentric with the axis of the cell, in which it is fixed, any motion of this latter, by ſcrewing or unſcrewing it, may not only change the place of the focus to which the wires are adjuſted, but will neceſſarily move the line of collimation both in right aſcenſion and declination. To obviate this, therefore, two correſponding marks ſhould be made with a graver, both upon the cell into which the glaſs is burniſhed, and alſo upon the tube of the teleſcope into which the cell is ſcrewed, or otherwiſe inſerted, that in caſe the object-glaſs ſhould ever be taken out to clean it, &c. it may be reſtored very nearly, if not exactly, to its former poſition.

The eye-glaſs, object-glaſs, and wires being thus ſettled in their reſpective places to each other, it will not be an improper time to meaſure the interval between the wires, which cannot be too accurately done, being of ſuch conſtant uſe; this may be either, 1ſt, by obſerving the paſſage of a ſtar in the equator, and making proper allowances for the rate of the clock, or by a ſtar out of the equator, and making proper allowances for the declination in the proportion of the radius to the coſine, or, 2dly, by means of the equatorial circle, and a fixed land object; and here the quantity muſt be diminiſhed in the ſame ratio as the radius to the ſine of the polar diſtance. We have made uſe of both methods as a confirmation of each other, and find the interval, which is equal in the three wires of my teleſcope, to be $7' \, 34''.5 = 30''.3$ ſiderial time; and theſe three wires divide the diameter of the field very nearly into four equal parts.

Second and third adjuſtments: *the hanging level.* By means of its proper handle *u*, move the declination circle about its axis, till the bubble of the hanging level *l m* reſts true between the indexes; there fix it by the clamp *w*, reverſe the level by taking it out of its pivots, and turning it end for end; if the bubble now ſtand true, the level is adjuſted; if not, correct $\frac{1}{2}$ the error by the declination handle, and the other $\frac{1}{2}$ by the ſmall ſcrew at the bottom of the level; then reverſe the level and repeat this operation till it does. The level, or rather a tangent to its curvature at its middle, will be parallel to the axis on which it ſwings, and both will be horizontal. At this time look through the teleſcope, and ſee what land object is covered by the horizontal wire; now invert the teleſcope by turning it 180° round the declination axis, and 180° round the polar, and bringing the level true, it will then point to nearly the ſame place; and if exactly the ſame object as before be now covered by the horizontal wire, the axis of the level is adjuſted parallel to the line of collimation in a vertical direction, if not, correct half the error by the little capſtan ſcrew at the bottom of the cock, or arm, that ſupports one end of the axis of the level, and the other half by the declination handle; invert the teleſcope, and repeat the operation, till the ſame object is covered in both poſitions, and the level is found true, then will the level and its axis be parallel to the line of collimation, and the object covered by the wire may be concluded to be in the horizon.

Fourth. *The index wires of the microſcopes.*—The line of collimation, with reſpect to eaſt and weſt, has been already adjuſted as above. Let then the declination axis, by its level, be reſtored to an horizontal poſition; at this time adjuſt the index wires in the two equatorial microſcopes W, X, to biſect the two oppoſite diviſions 360° and 180°, then will theſe wires be rectified to their proper place. That being done, bring 90°, or the diviſion that repreſents the equator on the declination circle, under its reſpective microſcope, and turn the whole inſtrument one quarter round on the polar axis, *viz.* till 90° on the equatorial circle be biſected by the micrometer; and, if at this time the bubble of the hanging level appear true, the index wire of the declination microſcope is correct; if not, correct $\frac{1}{2}$ the error by the declination handle *u*, and $\frac{1}{2}$ by the little ſcrews at the ſide of the hanging level, then reverſe the teleſcope, *viz.* turn it till 270° on the equatorial circle come under the micrometer wire, and if the level then reſt true the adjuſtment is complete; if not, repeat the operation, as before, till it does; then by its proper ſcrew bring the index wire of the declination micrometers to biſect the points 90° and 90°. The indexes of both circles will be then adjuſted, and the axis of the hanging level brought parallel to the line of collimation, with reſpect to eaſt and weſt, as well as with reſpect to north or ſouth. Note, this paralleliſm of the axis of the level, to the line of collimation in a direction eaſt and weſt, does not appear to be a very important rectification, but on ſome occaſions may have its uſe.

Fifth. *The refraction piece.*—After what has been done, this apparatus will be adjuſted. Bring the teleſcope, by means of its two levels P *k*, and *l m*, to point to the horizon, and in the meridian; then by the two points, *f*, *h*, *Plate* XI. *fig.* 2, of the refraction piece, bring its two levels *e* and *g* to reſt true; move the nonius *d*, of the little ſemicircle of the horary and vertical angles, *a*, *b*, *c*, to the middle of the diviſions, or 0°, 0′, and alſo that of the little quadrant of altitude, *l k*, to 0°, 0′, and this part is adjuſted.

Sixth. *The microſcopes.*—The magnifying power and ſcale of the microſcopes is all that remains to be conſidered. The magnifying power of a compound microſcope, as is well known, depends on the proportion between the diſtance of the object, and of its image from the object-glaſs, together with the proportion between the focus of the eye-glaſs and the ordinary focus of the eye looking at a ſmall object (ſuppoſe) of $\frac{1}{50}$th or $\frac{1}{100}$th inch. Theſe two ratios compounded give the power of the microſcope. The former is called magnifying by diſtance, and is a material part in the conſtruction of theſe microſcopes; the ſcale of the micrometer being regulated by this part of the magnifying power. For example, let the diſtance of the object from the glaſs be = 1, and the diſtance of its image = 4, its power will be 4; and conſequently the ſcale of the micrometer or motion of its ſcrew, to anſwer to 10′, (ſuppoſe) muſt be 4 times as great as the ſpace occupied by 10′, on the limb of the circle; and if the radius of the circle be two feet, an arc of 10′ will be equal to 0.07 inch nearly on the limb, and = 0.28 inch on the ſcale, *viz.* = to the ſame arc on a circle of 8 feet radius; and if each revolution of the micrometer ſcrew be intended to deſcribe 1′, the ſcrew muſt contain about 35 threads in an inch. But as it would be difficult to adjuſt the ſcrew exactly to the ſcale, the advantage of the conſtruction of theſe micrometers is, the ſcale may at any time be adjuſted to the ſcrew; for let the interval between any two neareſt diviſions = 10′ on the limb, be meaſured by the ſcrew, and, ſuppoſe, inſtead of being = 10′ or 600″, it appears only = 570″; it is evident that the ſcale is bigger than it ſhould be, or, which is the ſame thing, that the image is leſs by $\frac{30}{600}$ or $\frac{1}{20}$. In this caſe, increaſe the diſtance between the micrometer wires and the object-glaſs = $\frac{1}{20}$, by unſcrewing or drawing out the tube that carries the micrometer and eye-glaſſes, and the ſcale is adjuſted. It will, at the ſame time, however, be right to re-adjuſt the object-glaſs of the microſcope to diſtinct viſion, by the ſcrew of the cell that contains it, until the image and the wires have no relative change of place by any motion of the eye. This will again occaſion ſome ſmall alteration in the ſcale, and muſt be corrected by repeated trials, and the ſcale adapted to the diviſions on the arc; and if the moveable wire of the microſcope be now brought to coincide exactly with the fixed one, and the moveable index brought to zero on the ſcrew-head, the micrometer is completely adjuſted. This having been done with all the microſcopes, and the oppoſite ones being made to agree, each with the other, in ſuch manner, that the fixed wires may become a correct diameter, the whole inſtrument will have been completely adjuſted.

Before taking an obſervation of right aſcenſion and declination, the teleſcope muſt be adjuſted to the meridian mark, ſo as that the centre wire may exactly biſect it, in which ſituation care muſt be taken to make the index wires of the equatorial micrometers biſect the points of 360° and 180°, by means of the adjuſting ſcrew of the polar axis; and when an obſervation is made out of the meridian the altitude and angle of the horary and vertical circles muſt be taken by the refraction apparatus; then with theſe arguments, the refraction and parallax, in north polar diſtance, and in right aſcenſion, may be found by inſpection in the ſubjoined tables, by which any obſervation may be readily reduced to the meridian.

In this account of ſir George Shuckburgh, the reader may have obſerved, that the *order* of the adjuſtments propoſed is not that which is beſt in practice; as ſome of the *leading* adjuſtments muſt neceſſarily be deranged by the ſubſequent ones as he has deſcribed them, and indeed ſo as to tender new adjuſtments neceſſary; but we were unwilling to transform the baronet's directions that have met with the approbation of the Royal Society, though we cannot diſmiſs the account without this remark for the reader's conſideration; *viz.* the rectification of the teleſcope, levels, &c. ought certainly to *precede* the adjuſtments of the circles, that depend on *their* accuracy of poſition.

The Armagh equatorial inſtrument by Mr. Ed. Troughton.— The inſtrument which now claims our attention is repreſented in *Plate* XVI. of *Aſtronomical Inſtruments*, and, though ſimilar to its predeceſſor ſhewn in *Plate* XV, as to its uſe and properties, yet forms a ſtriking contraſt with it, in regard to compactneſs and beauty; too evident a contraſt indeed to be overlooked at the firſt glance of comparative inſpection. The arrangement of its principal parts is ſo novel, and at the ſame time ſo natural, as well as the connection of its ſmaller ones effected with ſuch ſymmetrical preciſion, that the mind is ſtruck with the contemplation of it, and ſpontaneouſly conſiders it as an inſtrument of a ſuperior order, that ſeems to place at a diſtance every other individual of its kindred: we therefore feel a peculiar pleaſure in concluding our article with the account of an inſtrument, which, though it comes laſt, ought in our eſtimation to ſtand firſt, as a model for future imitation. As the different component parts of the equatorial inſtrument are now become familiar to the reader, who has peruſed the preceding deſcriptions, we ſhall ſatisfy ourſelves with a brief detail, unaccompanied by alphabetical references to the drawing, which preſents a perſpective view of all the leading features.

The horary or equatorial circle, without centre or radii, occupies the middle part of the inſtrument; and is held in its proper place by eight conical tubes of braſs, four above and four below, which converge reſpectively towards the upper and lower poles, and which ſtand at the diſtance of a quadrant from each other. A ſtrong and light frame is thus formed of the ſhape of two ſimilar cones joining their baſes at the horary circle, and connected near their ſummits by two pieces of metal that terminate each with a hollow cylinder of about two inches diameter; this frame is further braced by croſs connecting tubes, as well as by ſide braces, or props, in the manner ſufficiently explained by the figure; and the whole frame, thus firmly united, ſupplies the place of a revolving axis, and carries the horary circle round with it, when it is made to turn on its cylindrical pivots. On theſe pivots the horary circle was finally turned true, after the frame was united and made faſt in all its parts, ſo that the excentricity of the circle, if it had any previouſly, was done away, by being turned on its own pivots. The inferior end of the polar axis or frame is ſupported by a ſolid ſtone, about 30 inches above the floor, with which it has no connection to produce unſteadineſs; this ſtone is capped by an apparatus of ſtrong braſs work, in which is produced the adjuſtment for bringing the inſtrument into the plane of the meridian, as well as that for giving the polar axis its proper elevation. This lower end of the axis terminates in a hemiſpherical button of hardened and finely poliſhed ſteel, which preſſes endwiſe againſt a plane of agate, and is kept centrical by two rollers that form an angle to receive it on the lower part of the apparatus; all which contrivances may be readily conceived without more minute deſcription. The ſupport for the elevated pole conſiſts principally of a ſtone pier, reaching from the ground to the centre of the inſtrument; but on it is firmly fixed a ſtrong frame of wrought iron, ſo conſtructed as to turn its edges towards the teleſcope hereafter deſcribed, in every direction; otherwiſe it would obſtruct the field of view in elevations below the upper pole. The upper gudgeon is received between two rollers ſimilar to thoſe below, except that theſe are perforated, as well as the gudgeons, in order that as little light as poſſible may be intercepted when the teleſcope is pointed to the pole. At about ſix feet diſtance from each other, in the eaſt and weſt line, upon the ſame ſolid foundation that ſupports the bearing ſtone and pier, are firmly fixed two pillars of ſtone, each nearly three feet high; and on the tops of theſe are placed faſt two ſtrong cones of braſs to ſupport the microſcopes for reading off the horary angles. The length of theſe two cones of braſs is ſo proportioned as to correſpond to the effective length of one half of the frame, or polar axis, in its inclined ſtate, in all changes of temperature, by which means the microſcopes preſerve their relative ſituations at the horary circle. This circle is divided into 5′ ſpaces, or ſpaces of 20 ſeconds of time, upon its extreme or exterior edge, which was made broad for this purpoſe, and the heads of the equatorial micrometers are ſo divided as to ſubdivide the ſaid ſpaces into tenths of a ſecond of time. The axes of the microſcopes of courſe are horizontal. At the tops of the conical parts of the pillars are adjuſtments for moving the microſcopes; one with reſpect to perpendicular height, another with reſpect to the diſtance of the exterior edges of the horary circle, and a third along its plane. An apparatus alſo for quick or ſlow motion is attached to each of the cones in queſtion, by means of which the inſtrument may be ſecurely fixed, either in the meridian, or in any other given poſition, as it regards the meridian. The declination circle likewiſe occupies the middle of the frame, and has its centre preciſely in the ſame point that is the centre alſo of the horary circle, theſe two circles being concentric, but having their planes exactly at right angles to each other, after the manner of the meridian and equatorial circles of a common ring-dial, when put into a ſtate for uſe. The declination circle is double, or compoſed of two complete circles united in ſeveral places by connecting pillars, and having each eight radii alſo connected in the ſame manner, after being inſerted into the common axis, which is of the ſhape of a double cone. The teleſcope paſſes through the baſes of the united cones of the axis, and has an aperture of 2¾ inches, conſequently the connecting pillars are long enough to admit ſuch a teleſcope between the united circles, in which ſituation it is not very eaſily diſtinguiſhable in the figure. Its eye-piece, however, is diſcernible juſt under the declination circle. It is 44 inches long, and revolves within the horary circle; conſequently requires a diagonal or reflecting eye-piece when directed to the equator, in which ſituation the aperture admits light enough, notwithſtanding the interpoſition of the horary circle. When the elevation is great, the head of the obſerver muſt neceſſarily be admitted between two out of the four lower conical pillars of the frame, which circumſtance points out the ſcale of magnitude on which an inſtrument of this conſtruction ought to be made, to be uſeful at all degrees of elevation of the teleſcope. The teleſcope has various magnifying powers, which may be uſed according to circumſtances. Two oppoſite quadrantal arcs of the horary circle have chord-bars parallel to each other, at the middle points of both which are ſockets for the gudgeons of the declination axis to work in as their ſupports: which bearings made the braces of the frame and horary circle eſſentially neceſſary to give ſtrength and firmneſs to the whole. The declination axis, which is about three feet long, has an adjuſtment at one end for ſetting it at right angles to the polar axis, and carries alſo a very ſenſible ſpirit-level parallel to itſelf; with another of which the teleſcope is likewiſe furniſhed, which it cannot be neceſſary to particularize further, after our former deſcriptions of ſpirit-levels, except that in thoſe the adjuſtment ſcrews had divided heads, whereas in theſe there are divided ſcales of ivory, by means of which the half differences can be accurately eſtimated to the *fraction of a ſecond.* The declination circle is divided into ſpaces of 5′, which are again ſubdivided by the microſcopic micrometers into minutes and ſingle ſeconds. One of theſe microſcopes is ſeen above the horary circle and the other below, but both are ſupported by it, and point horizontally to oppoſite points of the declination circle, as one of the others is ſeen at the top of one of the pillars pointing to the exterior edge of the horary circle. The apparatus for quick or ſlow motion, to govern the declination circle, is attached to the lower part of the frame, or polar axis, as repreſented in the figure. The excellence of this inſtrument has been fully eſtabliſhed in public eſtimation, by the uſe that has been made by Mr. Pond of the Armagh obſervations, taken with it in 1797, when he formed his catalogue of ſome of the principal ſtars, as we have already ſtated; in which catalogue (ſee our article DECLINATION,) it will be ſeen that the accuracy of its meaſures accord very nearly with the reſults derived from an average of the beſt modern inſtruments: and we may add, that the coincidence would doubtleſs have been ſtill more remarkable, had not the diviſions, which are by dots, been injured by an accident. An intenſe froſt, to which the inſtrument was expoſed at the top of the maker's houſe, covered it with black ſpots, and corroded its ſurface ſo as almoſt to obliterate the dividing points, which were neceſſarily enlarged by hand, and of courſe might be altered a little by this manual operation, however carefully performed. The diviſions of the other circle met alſo with an accident at the other ſide of the water, which, though of a different nature, has rendered the diviſions leſs correct than they were at firſt. Beſides which, two other circumſtances ought alſo to be named as drawbacks in this inſtrument, when compared with the circular inſtruments with which it has been contraſted, namely, its verifications were not made with a plumb-line; and its polar poſition may be conſidered as ſomewhat unfavourable for taking declinations with the utmoſt nicety; but notwithſtanding all theſe deductions, the accurate performance of the inſtrument has ſtood the teſt of a rigid compariſon with the inſtruments of three modern obſervatories.

Adjuſtments.—1. Turn the *wire-plate* round, if neceſſary, ſo as to make the middle vertical wire continue, throughout the whole field of view, on ſome diſtant and well defined point, while the teleſcope is elevated or depreſſed as it turns on the axis of the declination circle, to which the wire will in that caſe be perpendicular.

2. Slide the *object-glaſs* of the teleſcope in or out, while you view a ſtar of the ſecond magnitude, until the parallax of the wires is taken off, that is, until the viſion is as diſtinct as poſſible.

3. To adjuſt the *level* of the *declination axis.* By the motion round the polar axis bring the bubble of the level to the middle of the tube, and in this ſituation make its ſcales or indices to coincide with both its ends; turn the level, end for end, and if it now ſtand in the middle, as before, the axis is level; if not, alter one half of the deviation from the truth by a ſlight motion round the polar axis, and the other half by the ſcrews of the level itſelf; and repeat theſe rectifications till the bubble will ſtand always in the middle of the tube when its ends are reverſed. But the bubble of a hanging level may alſo require a lateral adjuſtment; to examine it in this reſpect, turn it round on its own axis a little, and if the bubble has a tendency to go to either end of the tube it muſt be rectified by the ſide ſcrews till this tendency is removed, and then if the bubble will yet bear reverſing, the level is properly adjuſted.

4. To adjuſt the *pivot-holes* of the level *parallel* to the *axis* of the declination-circle, and the *axis horizontal;* bring the bubble of the level to the indices on the tube, with the level above the axis, by moving the inſtrument round the polar axis; then turn the declination-circle half round till the level is under its axis, and if the bubble now ſettles to the middle, as pointed out by the indices, the level is right; if not, alter one half of the error by turning the polar axis round, and the other half by the two ſcrews that govern the pivot-hole; in the next place turn the teleſcope 90° round the declination-axis, and by the ſcrews that govern the other pivot-hole, bring the bubble to the indices, and the axis will be horizontal, as well as the pivot-holes parallel to it in all directions; for when the level itſelf is adjuſted, as above directed, it is evident that if the bubble keeps its place at the indices during a revolution of the declination-circle, the axis itſelf muſt neceſſarily be horizontal.

5. To ſet the *declination-axis* at *right angles* to the *polar axis*, we may uſe the level itſelf inſtead of the declination-axis, after it has been ſet parallel thereto as juſt directed; for this purpoſe, bring the bubble to the indices by moving round the polar axis, and biſect oppoſite points of the equatorial circle by the two wires of the microſcopes; turn the inſtrument exactly half round by the help of the microſcopes ſo adjuſted, and if the bubble now ſettles to the indices, the two axes are at right angles to each other; if not, alter one half of the error by the ſlow motion of the polar axis, effected by the equatorial tangent ſcrew, and the other half by the two ſcrews at one end of the declination-axis adapted for this purpoſe.

6. To ſet the *line of collimation* true in *right aſcenſion*, let the bubble be brought to the middle of the tube, or to the indices as in the laſt adjuſtment, and look at any well-defined ſmall object near the horizon, as biſected by the middle vertical wire; then having noted this mark, turn the inſtrument half round the polar axis, as indicated either by the level or equatorial microſcopes, which are now adjuſted to do the ſame thing; and when the teleſcope is turned back round the declination-axis, note if the ſame object or mark be interſected as before, if not, alter one half of the deviation by the equatorial tangent ſcrew, and the other half by moving the wires of the eye-piece in the teleſcope; thus when the ſame mark is biſected by the middle vertical wire, in reverſed poſitions of the teleſcope, the line of collimation will be right with reſpect to right aſcenſion.

7. To place the *indices* of the declination-circle to read *polar diſtances* truly. Before we deſcribe this adjuſtment, it may be proper to remark, that the microſcopes themſelves of this circle have each three ſeparate adjuſtments, the firſt, that which alters the power by altering the diſtance of the object lens, ſo as to make one minute on the circle equal to a revolution of the micrometer ſcrew; the ſecond, that which produces diſtinct viſion by varying the diſtance of the entire microſcope from the diviſions of the circle; and the third, that which places zero on the ſcale of minutes to agree with zero on the declination-circle, and alſo zero on the ſcale of ſeconds, to agree with zero on the ſcale of minutes, as effected by the head of the micrometer being made to turn independently of the ſcrew. Theſe minor adjuſtments being underſtood, point the teleſcope to any diſtant land object, and let the middle horizontal wire biſect it, and read off the polar diſtances ſhewn by the indices, and take half their ſum; make

the ſame obſervation when the inſtrument is turned half round the polar axis, and take another mean of the angles now ſhewn by the oppoſite indices; ſubtract the former mean from 180°, and add the difference to the latter mean, and *half of this ſum* is the angular diſtance from the pole of the inſtrument, to which quantity the indices muſt be put within the exactneſs of a minute or ſo, as this proceſs muſt hitherto be conſidered as an approximation only: repeat the operation we have deſcribed of obtaining two means of polar diſtances more accurately by uſing the ſcales of minutes and ſeconds; thus, read off by the indices the quantity to the diviſion next below the ſub-diviſions to be meaſured by the ſcales; then turn the micrometer head till the wire of the microſcope biſects the next following point, taking care to count the notches paſſed over as minutes, and the ſeconds and parts on the micrometer ſcale to be added to the quantity given by the indices alone; and the *ſupplement* of the mean of the two meaſures by the microſcopes, added to the mean read off in the ſame way, when turned half round the polar axis, being divided by two, will give the *true* angle from the pole of the inſtrument; and the ſcale of minutes, as well as ſcale of ſeconds on the micrometer head, muſt be finally adjuſted thereto.

8. To place the *declination-level parallel to the line of collimation* of the teleſcope, bring the declination-axis level, or nearly ſo, and let the bubble of the declination-level be brought to the middle of its tube, by the motion round the polar axis, and let the indices be put to its ends; turn the level a ſmall quantity round its own axis, and try if the bubble has any tendency to either end; if it has, adjuſt it laterally by the ſcrews that move one of its pivots ſideways, till it is right in this reſpect; now reverſe the level, and if the bubble does not ſtand in the middle, alter one half the error by moving the teleſcope in declination, by means of its ſcrew for ſlow motion, and the other half by the ſcrews that govern the pivots of the level, and the level itſelf will then be adjuſted. In this ſituation of things look for ſome object in the centre of the field of the teleſcope, and note it; turn the inſtrument half round the polar axis, and as much round the declination axis as to bring the teleſcope exactly to the ſame object again; if the bubble now ſtands in the middle, the adjuſtment is right, but if otherwiſe, one half of the error muſt be altered by the motion of the teleſcope in declination, and the other half by altering the pivot-hole of the level. Laſtly, turn the inſtrument the ſpace of *ſix hours* round the polar axis, and adjuſt the other pivot hole till the bubble ſtands in the middle of its tube, and the adjuſtments are all complete, provided the polar axis of the inſtrument be exactly parallel to the axis of the earth, which we have all along taken for granted, and which may be effected by its own adjuſtments as pointed out by an obſervation of a circum-polar ſtar, agreeably to our directions given under our article EQUATORIAL *Sector*.

EQUATORIAL.

Nº I. TABLE of the Effect of Refraction in North Polar Distance.

Refraction in Right Aſcenſion × Sec. of Declination.

This correction is − on the Eaſt, and + on the Weſt ſide of the Meridian.

EQUATORIAL.

Nº I. TABLE of the Effect of Refraction in North Polar Diſtance—*continued.*

This correction is always +

Explication and Uſe of the Tables.

The three firſt tables are particularly calculated for the uſe of a large equatorial inſtrument, for the purpoſe of clearing obſervations made with it from the effects of refraction and parallax, when neither Dollond's refraction apparatus is uſed, nor the micrometer circle of Ramſden's for adjuſting the wire uſed in taking altitudes; but the four laſt are adapted more peculiarly for portable inſtruments. They are copied from ſir George Shuckburgh's account in the Philoſophical Tranſactions, and, being adapted for all latitudes, are a ſuitable appendage to the deſcriptions we have given of the different inſtruments.

Table I. gives the correction of the refraction in north polar diſtance, by entering it with the altitude at the top, and the angle of the horary and vertical circles on the left hand ſide; and in the common point of meeting is found a quantity in ſeconds and decimal parts, that is in all caſes to be *added* to the *apparent* polar diſtance to give the *true*; but if it be entered with the angle of the horary and vertical circle in the right hand column, it will give the refraction in right aſcenſion, by multiplying the quantity here found by the ſecant of the declination to be found in Tab. IV., which is a readier operation than dividing by the coſine, and amounts to the ſame thing.

Table II. gives the effect of the ſun's parallax in right aſcenſion and north polar diſtance, and is to be entered with the ſame arguments as Tab. I.; and the parallax in right aſcenſion is to be multiplied by the ſecant of the declination as before; the ſun's horizontal parallax being aſſumed = 8.″6.

Table III. is a ſimilar table, only calculated to an horizontal parallax of 10″; ſo that whatever be the parallax of the ſun or planets, this correction may readily be found, almoſt by inſpection, *viz.* by multiplying the tabular number by the exact quantity of parallax of the body obſerved, and cutting off the decimal quantity.

Table IV. contains the natural ſecants to each degree, extracted from Sherwin's tables, to be ready for the operations required above.

Table V. gives the correction of the *time*; *viz.* of the ſun or ſtar's diſtance from the meridian, as aſcertained by a portable inſtrument not previouſly adjuſted to the meridian; this quantity alſo is to be multiplied by the ſecant of the declination.

Table VI. gives the correction of the meridian line in minutes and decimals, which may be near enough for portable inſtruments; but the quantity here found muſt be multiplied by the ſecant of the altitude.

Table VII. (like Table I.) is adapted to ſeconds of *time*, and gives the refraction in right aſcenſion in terms ſuited to ſuch inſtruments as have the equatorial circle divided into hours and minutes.

Table VIII., in like manner, gives the refraction in declination. The arguments are the ſame in all the tables.

Theſe tables were conſtructed by ſir G. S. in the year 1774, for his own uſe, and were founded on the principles explained by the Hon. S. M'Kenzie in *fig.* 4. of *Plate* XIII., where I F is a portion of a vertical circle = the refraction in altitude; C F a parallel to the equator; I C a portion of an horary circle = the refraction in declination, found by Tab. I and Tab. VIII., the angle C I F, the angle of the horary and vertical circle; C F the refraction in right aſcenſion, found by Tab. I. and Tab. VII.; D I (a parallel to the horizon) the correction of the meridian, found by Tab. VI.; and D F the correction of the time, found by Tab. V; and as I F will hardly ever be found to exceed 30′, theſe triangles have been conſidered all as plane; making due allowance, in the proportion of the ſine to the radius, for the diſtances of the arcs D I, F C, and D F, from their reſpective poles, which has been noticed at the foot of each table. The refraction in altitude was taken from Mayer's Tables, 1770, London; which is calculated for a denſity of the air expreſſed by 29.6 inches of the barometer, and 50° of Fahrenheit's thermometer.

EQUATORIAL *Micrometer*, is an apparatus applied to a teleſcope, that has an equatorial motion, for the purpoſe of meaſuring ſmall differences of right aſcenſion and declination of any two heavenly bodies, that paſs either ſucceſſively, or at the ſame time nearly, through the field of view, ſo as to be both viſible at the ſame elevation of the teleſcope. This method requires no graduated circles with verniers or compound microſcopes, and yet is capable of great accuracy within certain limits of difference between the relative ſituations of the bodies to be compared together; and if the right aſcenſion and declination of one of the two obſerved bodies be previouſly known with ſufficient accuracy, the place of the other can be determined therefrom by the obſerved differences. The common wire micrometer has been long in uſe as an appendage to the eye-piece of a teleſcope, and was uſed by Dr. Bradley in making aſtronomical obſervations, his manner of doing which was communicated to the Royal Society in the year 1772 (vol. lxii.) by Dr. Maſkelyne; but as the teleſcopes then in uſe were from ten to fifteen feet long, for want of the achromatic object-glaſſes, an equatorial motion was given, not from one centre, but by means of ſupporters at each end of the wooden tubes, ſo contrived as to be manageable both in altitude and azimuth; which apparatus is ſtill preſerved at the Royal Obſervatory. The wires of the micrometer have been adapted differently by different makers, ſome making only one moveable, and ſome more; but they all agreed in placing them in the focus of the eye-piece of the teleſcope. It is not, however, our intention to enter into a detail in this place of all the different conſtructions of the micrometer, as applied to various purpoſes, but to confine ourſelves to a notice of thoſe that have been more particularly applied to teleſcopes having an equatorial motion. For the other conſtructions, we refer to the article MICROMETER.

Soon after the diſcovery of the properties of the achromatic object-glaſs of a teleſcope had reduced the length of the aſtronomical teleſcope to a portable ſize, without diminiſhing either its power or ſize of its field of view, not only were equatorial inſtruments contrived of various conſtructions, as we have already deſcribed, but equatorial ſtands for ſimple teleſcopes were invented, and continue to be in uſe with the beſt teleſcopes to the preſent day. To theſe teleſcopes the micrometers are a very neceſſary and uſeful appendage, inaſmuch as they render it capable of being applied with advantage in aſcertaining the right aſcenſion and declination of a comet, planet, or other body out of the meridian, when they happen to be near enough to a known body to admit of being taken into the ſame field of view without altering the elevation. Though the wire micrometer was firſt invented, as applied to the focus of the eye-piece, and continues to be uſed in many inſtruments, yet ſince the invention of the achromatic object-glaſs, Dollond's object-glaſs micrometer has by ſome aſtronomers been preferred, or at leaſt deemed equally uſeful, particularly when the croſs wires are alſo uſed in conjunction, as deſcribed by Dr. Maſkelyne in his paper on this ſubject read to the Royal Society of London on Dec. 12, 1771, which was the year after Smeaton finiſhed his wire micrometer, that had been begun about forty years before. If we give an account of theſe two kinds of micrometers in ſucceſſion, the reader will perceive the varieties that may ariſe from them by ſlight deviations of conſtruction. We will begin with Smeaton's, as being of prior origin.

We are not aware that Mr. Smeaton has left behind him any perſpective drawing of his equatorial micrometer, though we have heard that there is an undeſcribed ſketch of one among his papers, at preſent in the poſſeſſion of Mr. Lloyd; but there is a ſection of one accompanying his paper read to the Royal Society of London on June 7, 1787, which is ſufficient for explaining the principle of its application. *Fig.* 3. of *Plate* XIII. of *Aſtronomical Inſtruments*, is the ſaid ſection, as viewed from the eye-end of the teleſcope. "This micrometer," ſays the author, "is furniſhed with five horary wires, denominated in their order, *a*, A, B, C, D, (B being the middle horary wire,) and the two declination wires are denominated A, B, each moveable by a ſeparate and independent micrometer-ſcrew, from the outſide of the field to the centre, and a little beyond it; ſo that each wire can be moved into the place of the other, when at or near the centre." The field of view was only 1° 17′, and the magnifying power as low as 20, with an eye glaſs of $1\frac{3}{4}$ inch focus, and a double object-glaſs of $34\frac{2}{3}$ focal length; notwithſtanding the author calculates that a difference of only $2\frac{1}{2}''$ may be read by ſuch apparatus, which he concluded was near enough for any inſtrument to read out of the meridian. In the conſtruction of the ſtand every thing was done to enſure ſtability of poſition at any given elevation, and the fruſtum of an hexagonal ſtone was uſed as a pedeſtal, detached from the floor of the obſervatory. With an apparatus ſo ſteady, it was not neceſſary to confine the obſervations to two bodies, to be compared, whoſe difference of right aſcenſion was only a few minutes, but even hours could be admitted of for the interval of the ſucceſſive tranſits, provided the difference of the declinations did not exceed the interval between the two adjuſtable croſs wires. The difference of the right aſcenſions was eaſily aſcertained by a regulator or chronometer, meaſuring the interval between the tranſits, and the diſtance between the bodies as meaſured by the interval between the croſs wires, gave the difference of the declinations. The firſt trial of the ſteadineſs and accuracy of this apparatus was made with Saturn and γ Capricorni, from which it was found that the ſtar had the ſame right aſcenſion and declination, determined on two ſeparate evenings, at the diſtance of 48 hours, though the inſtrument had not been touched during the interval. But the principal obſervations noticed in the memoir, are thoſe relating to the elongation of Mercury, as taken from Sep. 23, to Oct. 13, 1786, the reſult of which was, that at $5^h\ 22^m\ 35^s$ mean time on Sep. 23, A.M. Mercury's right aſcenſion, deduced from a compariſon with *a* Orionis, was 163° 59′ 21″, and his declination north 7° 44′ 25″. For the particulars of the calculations and the tables of the obſervations, ſee the Phil. Tranſ. of 1787. Alſo for the manner in which a ſimple teleſcope may be made to move in an equatorial direction, ſee our article Equatorial *Stand* of a teleſcope.

The object-glaſs micrometer of Dollond, of his moſt improved conſtruction, is repreſented by *fig.* 4. of *Plate* XII. agreeably to a drawing given in Mr. Dollond's pamphlet that accompanies his equatorial inſtrument. By the improvement, ſays the author, this micrometer has received, it is rendered capable of being applied to teleſcopes of ſmall aperture; the focal length of the object-glaſs being conſiderably increaſed, the ſcale by which the angles are meaſured is much enlarged. By this increaſe in the focal length of the object-glaſs of the micrometer, the perfection of the teleſcope is leſs injured; but the greateſt advantage that is derived from the improvement, is the length of the ſegments, which admit of the whole aperture of the teleſcope, even in meaſuring the largeſt diameters of the ſun or moon, and the object retains the ſame brightneſs in meaſuring the largeſt angles as in meaſuring the ſmalleſt.

Notwithſtanding theſe ſeveral advantages, the inſtrument is greatly reduced in ſize, as will appear by inſpecting the figure repreſenting the micrometer on the end of the teleſcope; the deſcription of which is as follows:—

a and *b* are two long ſegments of an achromatic object-glaſs, divided into ſeparate pieces by a diametrical line, and fitted into ſeparate frames, ſo that by ſliding one or both the ſegments, they may be made to form in effect either one object-glaſs or two, it being the property of half a well ground glaſs to give as diſtinct an image as the whole would do; the ſegment *a* is moved by turning the milled head *c*, and the ſegment *b* is moved by turning the handle *d*. When an obſervation is to be made, it is generally known what number of minutes the angle will contain nearly; ſuppoſe, for example, the diameter of the ſun were to be meaſured, which is known to be about 32′; move the ſegment *a* till the index *c* comes to 32 on the ſcale *ff*, then looking through the teleſcope, move the ſegment *b*, by turning the handle *a* till the circumferences of the two images, formed reſpectively by the two ſegments, are brought to touch one another externally, and the quantity that the ſegments have moved will be meaſured by the ſcale *gg*, and vernier *h*, by which an inch is divided into five hundred parts: the greateſt exactneſs is required in this ſcale, as the angle is abſolutely to be determined by the meaſure taken with it; the ſcale *ff* being only of uſe to ſet the ſegment *a*, ſo that in meaſuring the angle by moving the ſegment *b*, they may be both moved nearly the ſame quantity.

The handle *i* is to turn the micrometer round, to bring the line dividing the two ſegments of the object-glaſs into the plane paſſing through the two objects, whoſe diſtance is to be meaſured. It is neceſſary, in making obſervations with the micrometer, that the teleſcope, when the micrometer is on, be adjuſted to the *moſt perfect viſion* of the object to be obſerved, as a ſmall error in this reſpect may occaſion a conſiderable difference in the obſervation. To find if there is any error in the adjuſtment of the micrometer ſcale *gg*, turn the handle *d*, ſo as to make the two images perfectly unite, and the number ſhewn by the ſcale and vernier will be the error of adjuſtment, if there is any; this error may either be allowed for in the obſervations, or be corrected by the vernier ſcrews at *k*. The object proper to be uſed for adjuſting the focus of the teleſcope with the micrometer on, may be any of the celeſtial bodies, or ſome diſtant well defined land object; but for adjuſting the micrometer ſcale, the object may be nearer, ſuch as a printed paper at two or three hundred feet diſtance, provided the focus be firſt well adjuſted to this object. A table is uſually given with the micrometer, which ſhews the number of minutes and ſeconds anſwering to the diviſions on the ſcale. When the micrometer is on the end of the tube of the teleſcope, it is neceſſary that the ſcrew at the centre of motion be tight, otherwiſe, which is better, that there be a counterpoiſe at the eye-end to preſerve the equilibrium in any elevation. Alſo, as the object-glaſs of the micrometer is concave, the common focus of the object-glaſs of the teleſcope end of it is lengthened, which circumſtance requires the tube of the eye-glaſs to be longer than when the teleſcope is uſed without the micrometer.

The properties peculiarly aſcribable to the two kinds of micrometers we have deſcribed are, that the one at the focus of the eye-glaſs is adapted for meaſuring the differences of right aſcenſions and declinations of two bodies, one of which has its plane known; but the one placed at the object end of the teleſcope is calculated, by means of its graduated ſcale, to meaſure abſolute ſmall diſtances; and the accuracy of its ſcale may be brought to the teſt by a compariſon with a known interval between two ſtars or other diſtant bodies. Dr. Maſkelyne, in the paper we have already noticed, has however ſhewn how, by the addition of two croſs-wires in the focus, the differences of right aſcenſions and declinations may alſo be meaſured by Dollond's micrometer, thus: "Suppoſe it be required to meaſure the difference of right aſcenſion and declination of two ſtars, whoſe difference of declination does not exceed the extent of the ſcale of the micrometer, and the diſtance of the meridians paſſing through the ſtars does not exceed the ſemi-diameter of the field of view, turn the wires about till the weſtern ſtar runs exactly along the croſs-wire by the diurnal motion; then ſeparate the two ſegments of the divided object-glaſs to a convenient diſtance, and turn the micrometer about, by means of its proper handle, till the two images of the ſame ſtar, formed by the two ſegments of the object-glaſs, paſs the horary or vertical wire at the ſame inſtant. Laſtly, partly by the feet-ſcrews of the ſtand, and partly by the handle that ſeparates the ſegment, cauſe the ſouthermoſt image of the northermoſt ſtar, and the northermoſt image of the ſouthermoſt ſtar to appear both upon and run along the croſs or horizontal wire: the numbers ſtanding upon the ſcale of the micrometer will then ſhew the difference of declination of the ſaid ſtars; and if the times be noted when they paſs ſucceſſively the horary or vertical wire, the difference of the two times will give the difference of their right aſcenſions alſo." (See Phil. Tranſ. vol. lxi. article xlix.) It was one of Dollond's object-glaſs micrometers, attached to an 18 inch reflecting teleſcope by Short, and another attached to a two feet reflector, that lieutenant (afterwards captain) J. Cook, of the Endeavour, and Mr. Charles Green, formerly aſſiſtant at the Royal Obſervatory, uſed in obſerving the tranſit of Venus over the ſun's diſc on June 3, 1769, in King George's iſland, or Otaheite, in the South ſea, as recorded in the ſame volume of the Philoſophical Tranſactions.

For an account of the hiſtory of the micrometer, and its various conſtructions by different artiſts and ingenious men, ſee the article MICROMETER.

EQUATORIAL *Sector*, an inſtrument ſometimes uſed in *Practical Aſtronomy*. This inſtrument was invented by Mr. George Graham, F. R. S. for meaſuring greater differences of right aſcenſion and declination of a heavenly body, as compared with another body, than the equatorial micrometer alone will give, and may be made of any convenient dimenſions. One of theſe inſtruments made by Mr. Graham, is yet preſerved at the Royal Obſervatory at Greenwich, and is occaſionally employed to determine the right aſcenſions and declinations of a comet or other body out of the meridian, for doing which it is ſtill found to be ſerviceable. Doctor Robert Smith has deſcribed the principle and conſtruction of Graham's ſector, in the year 1738, and Mr. B. Martin copied the account verbatim in his magazine, from one or other of which authors the different dictionaries have their deſcription tranſcribed.

Graham's Equatorial Sector.—In juſtice to the contriver of the equatorial ſector, we propoſe to deſcribe it agreeably to its original conſtruction; but as we have cauſed the different parts of the drawings, as given by Dr. Smith, to be thrown into one perſpective inſtrument, it becomes neceſſary to vary the detail accordingly. *Fig.* 1. of *Plate* XIII. (of *Aſtron. Inſtr.*) is a perſpective view of the principal parts of the ſector lying in its inclined ſtand or bed, which we have ſuppoſed to be firmly fixed to a ſloping pedeſtal, exactly parallel to the earth's axis. This inclined bed, A B, is a ſtrong brazen plate or bar, turned up at the ends in a perpendicular direction at C and D; the lower end C has a ſcrew, entering it from below, ſtrong enough to bear the inferior end of the ſector's axis E F G, the conical hole made in the end of the latter at E, reſting on the conical point of the former; the upper end D has a ſlit in it, into which the axis is demitted at the cylindrical part F, below the circular plate H attached to the axis. The whole length of the axis is 18 inches, of which the ſquare part E F is 12. On the poſterior part of the bent end D of the inclined ſupporting plate A B, is a clamp I, turning on two pivots, ſo that it may be elevated or depreſſed without turning round in an equatorial direction; this clamp fixes the circular plate H, in any given place on its edge from turning round, but adapts itſelf to the plate, ſo as to preſs equally on both ſurfaces, by means of its vertical motion on pivots; conſequently the axis E F G, to which the plate H is attached, may have a motion like the polar axis of the earth when wanted, and may be firmly fixed by the clamp acting on its plate in any given ſituation. At the ſuperior end G of the axis is fixed another circular brazen plate K L on one of the flat ſides of the ſquared axis, and having a motion round a pin with ſcrews and a tightening collar; on this plate a croſs of braſs is ſcrewed faſt, compoſed of four bars at right angles to each other, two of which bars conſtitute an inverted cock, on the bent parts of this the long radial bar M N is fixed, which is made ſtrong by an edge-bar on its under ſide. Whenever, therefore, the circular plate K L moves round its central pin at G, the radial bar, carried by it, partakes of its motion, and *vice verſâ;* this plate has alſo a clamp O, ſimilar to the clamp I in every reſpect, by which it may be made ſteady in any given ſituation. The length of the radial bar is $2\frac{1}{2}$ feet, and its breadth at M and N $1\frac{1}{2}$ and 2 inches reſpectively: at N is a ſmall arch of a circle, 6 inches long and $1\frac{1}{2}$ broad, graduated into 10°, and ſubdivided into quarters, that read and are figured both ways. Upon this radial bar is mounted a teleſcope P, of $2\frac{1}{2}$ feet in length, moveable on the point M, as an axis of motion, near the object-end, and having a vernier near the eye-end with 16 quarters of a degree divided into fifteen equal parts, ſo as to read off exact minutes. This vernier is moved by the nut of an endleſs ſcrew Q, that is adapted as an apparatus for faſt or ſlow motion, in the uſual way. The diameters of the two circular plates are each 5 inches, and the plates are ſtrong enough to hold the teleſcope in any given poſition that an obſerved body may require.

The polar axis E F G of this inſtrument muſt be placed *truly* in the meridian and parallel to the earth's axis, which may be done by bringing the teleſcope parallel to the axis itſelf, and, after fixing it, by following a circumpolar ſtar therewith, and noting the apparent path as it reſpects the interſection of the croſs-wires of the teleſcope: the deviation above or below the croſs-wire will point out the error of elevation of the axis, and the difference in the times of the ſtar's paſſage through the two ſemicircles, eaſt and weſt reſpectively, will diſcover the deviation from the meridian line; then half theſe errors may be corrected by the ſcrews that fix the inclined bar A B to the pedeſtal, and the other half by altering the poſition of the teleſcope, till, after ſeveral ſucceſſive trials, the ſtar will accompany the interſection of the wires through its entire circle. It is neceſſary, however, that the polar axis be placed, by means of a ſmall quadrant or other ſuch contrivance, very nearly in its proper degree of elevation, as well as nearly in the meridian on the pedeſtal previouſly to the adjuſtment by a circumpolar ſtar. It is alſo neceſſary that the line of collimation of the teleſcope be parallel to the plane of the ſector, as well as the latter at right angles to the circular plate H, which repreſents the equator; the former may have its truth examined by a diſtant plumb-line ſuſpended in a vertical poſition; for if the interſection of the croſs-wires of the teleſcope will paſs along this line, when the plane of the ſector is vertical, and when the teleſcope derives its motion from the ſcrew of the vernier alone, it may be concluded that the line of collimation is parallel to the plane of the ſector; but the plane of the ſector itſelf muſt be previouſly ſet right, as it regards the equatorial plate H, by the ſcrews that fix it to the inverted cock of the croſs, attached to the circular plate K L. From a conſideration of this inſtrument, as we have deſcribed it, it is obvious, that, provided the teleſcope, thus having a polar motion and bearing a graduated ſector, be made perfectly ſteady, and placed in the true direction of an hour circle in the heavens, the difference of declination of any two bodies in the celeſtial regions, that does not exceed the extent of the ſector's limb, may be meaſured to the accuracy of a minute of ſpace, and that whether the two bodies paſs the teleſcope together or ſucceſſively, provided the elevation of the teleſcope does not vary in the mean time; and alſo the difference of right aſcenſion of any two bodies, ſimilarly ſituated, may be had by noting the difference of ſiderial time, (by a regulator,) of their paſſages over the horary wire; provided the ſituation of the ſector itſelf does not alter while the teleſcope is raiſed or depreſſed; but much of the accurary of the reſults will depend on the ſteadineſs of the parts that are clamped. Were the equatorial ſector to be conſtructed at this time, the reading by a microſcopic micrometer would greatly enlarge the powers of this inſtrument.

"But however well adapted this inſtrument may be to the purpoſes for which it was intended," ſays profeſſor Vince (Treatiſe on Pract. Aſtron. p. 141, and ſec. 7.) "yet it will not conveniently admit of a large teleſcope; Dr. Maſkelyne, therefore, thought of a conſtruction which would admit of one of a larger ſize, and which has, beſides, ſeveral other advantages in reſpect to the adjuſtments, as will be evident when we come to deſcribe them. The inſtrument was made by Mr. Siſſon, the conſtruction of which we will firſt deſcribe, and then proceed to its adjuſtments."

Equatorial ſector by Mr. Jonathan Siſſon.—A B, in *fig.* 1. of *Plate* XVII. (of *Aſtron. Inſt.*) is a polar axis, H I a circle fixed upon, and at a ſmall diſtance from it, on the centre of which is an axis, about which the teleſcope C D turns, carrying the indices *a*, *b*, each having a vernier which ſubdivides to minutes, and the circle is graduated to ſhew north polar diſtances; this, which is called the croſs axis, goes through A B into a fixed caſe E on the other ſide, and is moveable by a ſcrew *q* in order to fix it perpendicular to the polar axis: L M is an arc of 22° fixed upon A B, and concentric with H I; *v w* is a vernier whoſe arm K may be ſcrewed to the axis on which the teleſcope turns, and conſequently in that caſe will turn with it, but if the ſcrews be releaſed, the teleſcope will turn without it. N O P Q is a braſs frame, the two ends of which, O N, P Q, conſiſt of two pieces, one of which goes over the arc L M, and the other under, ſo that by means of two ſcrews at *y* and *x* to preſs them together, the frame may be fixed to the arc, in which caſe the ſcrew *c d*, paſſing through a nut at *s* on the arm K, will move the vernier *v w*; V is a braſs circle graduated on the edge, and moveable with the ſcrew *c d*, againſt which is fixed a piece of braſs *r* as an index; W is a piece of braſs fixed on an immoveable piece of wood, on which is another piece not ſeen to receive the end of the axis B, and in which it turns, and this piece is moveable eaſt or weſt by a ſcrew of adjuſtment; the end turns in a braſs ſocket *e f*, moveable by a ſcrew T in order to alter the inclination of the axis A B, and thence adjuſt it to the latitude; R S is an equatorial circle fixed perpendicular to A B, having a vernier *m n*; this circle is divided into 24 hours, and each hour into minutes, and the vernier ſubdivides into ſeconds.

The adjuſtments are three; firſt, to ſet A B parallel to the earth's axis; ſecondly, to adjuſt the line of collimation parallel to the circle H I; thirdly, to adjuſt the croſs axis perpendicular to the polar axis. The firſt adjuſtment conſiſts of two parts, to ſet the axis at the proper angle, and to place it in the plane of the meridian. Now to adjuſt the axis to an angle equal to the latitude of the place, the inſtrument is ſuppoſed to be at firſt fixed as nearly as poſſible to the true angle, and then the error is to be corrected by adjuſtment; to do which, turn about the polar axis until the circle H I becomes perpendicular to the horizon, and direct the horizontal wire of the teleſcope to the pole ſtar, or any other whoſe polar diſtance is known, when it comes above or below the pole; then turn the axis half round (which is ſhewn on the equatorial circle); in which caſe the circle becomes perpendicular to the horizon again; then if the axis be at the proper angle, it is manifeſt that the teleſcope is now directed to a point as much below or above the pole as it was above or below before, that is, to the polar diſtance of the ſtar increaſed or diminiſhed by the refraction of the ſtar at the firſt obſervation; hence, if we turn the teleſcope till the ſtar be again obſerved at the ſame wire, the indices *a*, *b*, will have moved over twice the refraction, ſuppoſing the ſtar to be ſo near to the pole, that the refraction may be conſidered the ſame both above and below; for if the ſtar be firſt obſerved above, its apparent place is above the true, and therefore if the teleſcope and ſtar revolve about the axis till they come below, the teleſcope is now directed to a point below the true place by the refraction, and as the apparent place is now above the true place by refraction, the teleſcope is directed to a point diſtant from the apparent place of the ſtar by twice the refraction; but if it do not move over twice that diſtance, then half the difference is the error of the angle of the elevation of the axis; move the teleſcope therefore through twice the diſtance which the indices *a* or *b* will ſhew, then turn the teleſcope, and bring it half way to the ſtar, and by the ſcrew T bring the ſtar to the wire, and the axis is adjuſted to an angle equal to the latitude of the place; in the ſame manner we determine whether the axis be in the plane of the meridian, by obſerving the ſtar in the equator, either in the eaſt or weſt, and then turning the axis half round, if the axis be rightly adjuſted to the meridian, the teleſcope muſt be moved 180° in order to bring the ſtar to the ſame wire; hence if the teleſcope do deſcribe 180° the axis is right; if not, half the difference is the error; move, therefore, the teleſcope through 180, and then by turning it bring it half way to the ſtar, and by the ſcrew at top out of ſight bring it the other half, and the polar axis is truly adjuſted. Secondly, to adjuſt the line of collimation parallel to the circle H I. Obſerve a ſtar in the equator, and note the time of its tranſit over the middle wire of the teleſcope by a clock, adjuſt it to ſiderial time, and note alſo the time ſhewn by the vernier $m n$ on the hour circle R S; turn the polar axis half way round according to the order of the figures on the hour circle R S, and the vernier ſhews a difference of 12 hours; now as the line of collimation is firſt directed to the equator, it muſt be perpendicular to the polar axis, and therefore by turning the polar axis about, it muſt continue to be directed to the equator, whether or not it be parallel to the plane of the circle H I; and if this could be done, and the teleſcope turned about, and the obſervation repeated without loſs of time, the ſtar would appear on the ſame wire, provided the line of collimation were parallel to the plane of the circle H I, for then the line of collimation in the ſecond obſervation being parallel to what it was in the firſt, it muſt be directed to the ſame point in the heavens, the teleſcope being turned half round; but as this operation will take up ſome time, the polar axis muſt be turned a little more than half round in order to bring the ſtar to the ſame wire, and the vernier would point out the ſame difference of times as the clock ſhews in the interval of the obſervations; but if theſe differences of times ſhewn by the clock and the hour circle be not equal, the line of collimation is not parallel to the plane of the circle, and half that inequality of times is the error, which muſt be corrected by the adjuſtment for that purpoſe. Thirdly, to adjuſt the croſs axis perpendicular to the polar axis, or to the line of collimation. By the laſt adjuſtment, the line of collimation was made to move in a plane; therefore, if that plane be adjuſted to the polar axis, the line of collimation will deſcribe a ſecondary to the equator. On this ſuppoſition, if we take a ſtar of any declination, and note the time of its tranſit over the middle wire by the clock, and alſo the hour on the hour circle; then turn the polar axis half round, and obſerve again as in the laſt poſition, and the differences of the times of the two obſervations ſhewn by the clock, and on the hour circle diminiſhed by 12, muſt be equal; but if the line of collimation do not deſcribe a ſecondary, the differences will not be equal. To correct, therefore, this error, let E Q, *fig.* 2. *Plate* XVII. be the equator, E P Q a great circle paſſing through the pole P, E F Q the great circle deſcribed by the line of collimation, and let the teleſcope be directed to a ſtar at b, and let $d b y$ be a portion of its parallel, take $a d = a b$, and draw the ſecondaries P $d m$, P $b c$. Now it is manifeſt, that if we turn the polar axis half round, the plane E F Q will then lie as much on the contrary ſide of E P Q; and, therefore, when the teleſcope is directed to the ſtar's parallel, it will cut it at d, and half m C, or E c, is the error of right aſcenſion. Note the time on the hour circle, and continue to turn (in the preſent inſtance) the polar axis until the ſtar, now at x, on account of its motion, be again brought to the middle wire, and note again the time on the hour circle, and we have the difference $m r$ ſhewn by the hour circle, from which ſubtract the time $c r$, ſhewn by the clock between the obſervations, and we have m C, the half of which is E c. Now the ſtar being on the middle wire, move the polar axis ſo as to cauſe the hour circle to move through an arc $r s$ equal to E c, and by the ſcrew q, *fig.* 1, alter the poſition of the croſs axis, and conſequently of the plane E F Q till the ſtar appears again on the ſame wire, moving, if neceſſary, the teleſcope on the circle H I to bring the ſtar into the field; and then as $y x = a b$, the line of collimation would have been corrected ſo as to make it paſs through P, and the adjuſtment would have been truly made, provided the ſtar had not moved in the time of this laſt operation. Correct again, therefore, and you will get the line of collimation to deſcribe a ſecondary to the equator, when the teleſcope is moved on the circle H I. Thus the inſtrument is adjuſted for uſe.

To find any object in the heavens, whoſe right aſcenſion and declination are known.—Find its diſtance, at the time required, from the meridian in the uſual way, and reduce it to ſiderial time, and turn about the polar axis, that way the object lies from the meridian, until the hour circle points out that diſtance of the teleſcope from it; then turn the teleſcope till the indices a, b, ſhew the polar diſtance, and the object will be in the field of view. By this means we direct the teleſcope to a comet, or any other body whoſe place is known, which is inviſible to the naked eye.

To find the true place of a body, and trace out its path in the heavens.—Screw the index K to the croſs axis of the teleſcope; bring the body upon the wire parallel to the equator, and take the time of its tranſit over the middle wire perpendicular to it, and note the degrees on the arc L M, pointed out by the vernier $v w$; then if there be any known fixed ſtar near its parallel, move the teleſcope on the circle H I (the polar axis remaining fixed) to the ſtar's parallel, wait till the ſtar enters the field of view, and make it run along the ſame wire as the body did, and take the time of its tranſit at the middle wire, and the difference of theſe times will give the difference of their right aſcenſions, and the difference of the arcs on L M, pointed out by the vernier $v w$ at the times of the tranſits, gives the difference of their declinations; hence the right aſcenſion and declination of the body is known. Continue theſe obſervations as long as the body is viſible, and you will get its path in the heavens. The utility and convenience of this method is, that we can at any time determine the place of a body without waiting for its coming to the meridian; where, beſides the inconvenience of waiting, an obſervation might be hindered by the badneſs of the weather, or the body might come to the meridian in the day-time, when it could not be ſeen.

An inſtrument, ſomewhat ſimilar in conſtruction, but with conſiderable improvements, was begun by Mr. Bird in the laſt year of his life, or the year preceding, for the obſervatory at Oxford, and was finiſhed by Mr. Troughton (the ſenior) about the year 1773, by order of Mr. Bird's executors. We regret that we have not had the means, in due time, of obtaining a perſpective drawing of this inſtrument, that we might have gratified our readers with a deſcription of it.

EQUATORIAL *Stand* of a teleſcope is a contrivance for making a common teleſcope follow a celeſtial body in its apparent path along, or parallel to, the equator; and anſwers the purpoſe of a polar axis of motion, while it adds but little to the expence of a ſimple ſtand for horizontal and vertical motions only. The thing required to be done to a common ſtand, was to give the horizontal motion an equatorial direction, and then the vertical motion, of itſelf, becomes a motion in declination, or in an horary circle, as well out of, as in the meridian. Various methods have been deviſed of effecting this purpoſe in the ſimpleſt way; but the contrivance invented by Mr. Smeaton, uſually called Smeaton's Block, and which has all the advantages of cheapneſs, ſtability and ſimplicity, has been preferred to all others, and in our opinion merits a place in our collection of aſtronomical inſtruments.

Fig. 5. of *Plate* XIII. of *Aſtron. Inſt.* is a repreſentation of an equatorial ſtand of Smeaton's conſtruction, in which the three legs are of mahogany, well braced together, and ſhortened at the lower extremities for the purpoſe of bringing them within the plate. The part *a b*, at the top of the legs, in the ſhape of a blunt wedge, is of mahogany, and is faſt to the legs; the other ſimilar part *c d*, above it, is alſo mahogany, and ſloped exactly like the part *a b*; the two parts taken together are called the *block*, the lower half of which is fixed, and the upper moveable on a ſtrong cylindrical piece of braſs fixed to the piece *c d*, at right angles to the line of ſection, or plane of contact, and paſſing through the piece *a b* ſo as to be fixed, when neceſſary, by a finger ſcrew below the block, and within the junction of the three legs. The plane of contact of the two halves of the block is ſo ſloped as to make an angle exactly equal to one half of the co-latitude of the place of obſervation, with a horizontal line, in which the under-face of the block is ſuppoſed to be by its poſition; but as the upper half of the block is exactly ſimilar to the under one, its face, when in the preſent equatorial poſition, makes an angle with the horizon equal to the whole co-latitude of the place; *i. e.* when in the meridian, is coincident with the plane of the equator. When the part *c d* is turned half round, ſo that the point *d* may coincide with the point *a*, and the point *c* with the point *b*, the ſlopes of the two halves of the block are then reverſed, and the face of *c d* becomes horizontal: hence it appears that a motion of the half block *c d* round its axis of motion, will carry any teleſcope *g*, or other body, placed on it parallel to its face, in the direction of the equator, provided it be placed in the meridian of the place when it has the greateſt elevation. Accordingly an axis of motion of a ſmall graduated equatorial circle *e* is attached perpendicularly to the face of the half block *c d*, round which the ſaid circle is moveable; and over this circle is mounted a graduated ſemicircle of declination *f*, or of altitudes, when the block is in its horizontal poſition, to which the teleſcope is made faſt. The circle *e* is divided into half degrees, or two minutes of time, and is ſubdivided by a vernier into $\frac{1}{30}$th of this quantity, that is, into minutes of ſpace, and four ſeconds of time; the declination-ſemicircle is alſo ſubdivided into minutes of ſpace by a vernier; and by enlarging the radii the ſubdiviſions might be rendered ſtill more minute; but the uſe of theſe graduations is merely to *find* a ſtar or planet, by its right aſcenſion and declination, to which purpoſe the inſtrument is quite competent. Mr. Troughton informs us, that he has made this ſtand an univerſal one ſometimes, by dividing the block diagonally by an angle of 45°, in which caſe it would take any degree of elevation from a horizontal to a vertical poſition, and one of the half blocks, being graduated into 360°, was read by a vernier fixed to the other, ſo as to aſcertain any given quantity of elevation; but as the conſtruction of the inſtrument does not admit of great accuracy in its adjuſtments and motions, he conſidered ſuch addition rather as curious than really uſeful in aſtronomy. Still, however, when the teleſcope is fitted up with the beſt micrometer for meaſuring the difference of right aſcenſions and declinations, and when the ſtand is made very ſteady, the inſtrument may be very ſerviceable in an obſervatory, and is often made a part of its furniture.

The ſliding tubes *h* are ſometimes ſuperadded to brace the eye-end of the teleſcope, and are found to anſwer a good purpoſe, when well made, and fitted to any pair of the legs that may happen to be turned towards this end of the teleſcope. Both the equatorial circle *e* and ſemicircle *f* have the uſual apparatus for quick or ſlow motion; and when the block is in the horizontal poſition, the teleſcope may be fixed, by the finger ſcrew under the block, to be conveniently uſed for viewing terreſtrial objects; in which poſition the inſtrument makes no contemptible theodolite, as well as equal-altitude inſtrument, when a level is added.

EQUEA, in *Geography*, a town of Africa, on the Gold coaſt.

EQUERY, or Ecury, a grand ſtable or lodge for horſes, furniſhed with all the conveniences thereof; as ſtalls, manger, rack, &c.

The word is formed from the French, *eſcurie*, which ſignifies the ſame thing. Some again derive *eſcurie* from the Latin, *ſcuria*, which not only denotes a place for beaſts to be put up in, but alſo a grange or barn. But a more probable derivation is from *equile*, a ſtable for horſes, of *equus*, horſe.

Some hold that the word ſtable, in propriety, relates only to bullocks, cows, ſheep, hogs, &c. and equery, to horſes, mules, &c.

A ſimple equery is that provided for one row of horſes; a double equery that provided for two, with a paſſage in the middle, or two paſſages; the horſes being placed head to head, as in the little equery at Verſailles.

Under equery are ſometimes alſo comprehended the lodgings and apartments of the equeries, grooms, pages, &c.

Equery, *eſcuyer*, is alſo an officer who has the care and management of the horſes of a king or prince.

EQUERIES, or Equerries, popularly called *querries*, are particularly uſed amongſt us for offices of the king's ſtables, under the maſter of the horſe, five in number, who, when his majeſty goes abroad, ride in the leading-coach, are in waiting, one at a time, monthly, and have a table with the gentlemen-uſhers during the time, and a ſalary of 300*l.* a year each: that of the firſt equerry and clerk-martial being 500*l.*

They uſed to ride on horſeback by the coach ſide when the king travelled: but that being more expenſive to them than neceſſary to the ſovereign, it has been diſcontinued.

Equeries *of the crown ſtable*, have that appellation, as being employed in managing and breaking the ſaddle-horſes, and preparing them for the king's riding.

The equerry of the crown ſtable has an annual ſalary of 200*l.* and is, or always ſhould be, in cloſe waiting at court; and when his majeſty rides holds the ſtirrup, while the maſter of the horſe, or one of the equerries in his abſence, aſſiſts in mounting him; and when his majeſty rides, they uſually attend him. To the eſtabliſhment of the queen's houſhold belong two equerries with a ſalary of 220*l.* each. There are alſo two belonging to the prince of Wales's houſhold. Officers under the ſame denomination form a part of the eſtabliſhed houſholds of the royal dukes, &c.

EQUES Auratus, is uſed to ſignify a knight bachelor, called *auratus*, q. d. *gilt*, becauſe anciently none but knights might gild or beautify their armour, or other habiliments of war, with gold.

In law this term is not uſed, but inſtead of it *miles*, and ſometimes *chevalier*.

EQUESTRIA, among the Romans, a place in the theatre where the equites or knights ſat.

EQUESTRIS, Equestrian, formed of the Latin, *eques*, knight, horſeman, of *equus*, horſe, a term chiefly uſed in the phraſe equeſtrian ſtatue, which ſignifies a ſtatue repreſenting a perſon mounted on horſeback.

The Fortuna equeſtris, in ancient Rome, was a ſtatue of the goddeſs on horſeback. We ſometimes alſo ſay, *equeſtrian* column, which ſee.

Equestrian *cohort*, in *Antiquity*. See Cohors *equitata*.

Equestrian *games*, *ludi equeſtres*, among the Romans, horſe-races, of which there were five kinds, the prodromus, or plain horſe-race, the chariot race, the decurſory race, about funeral piles, the ludi ſevirales, and the ludi neptunales.

Equestrian *order*, among the Romans, ſignified the order of the knights or equites.

EQUI, in *Ancient Geography*, a ſmall town of Africa Propria, near a lake in the vicinity of Utica. According to Diodorus Siculus it was taken by Agathocles.

EQUIANGULAR, in *Geometry*, is applied to figures whoſe angles are all equal; ſuch are the ſquare, and all regular figures.

All equilateral triangles are alſo equiangular.

An equilateral figure inſcribed in a circle is always equiangular; but an equiangular figure inſcribed in a circle is not always equilateral, except when it has an odd number of ſides. If the number of the ſides be even, then they may be either all equal, or elſe half of them will always be equal to each other, and the other half to each other; the equals being placed alternately. See Hutton's Math. Miſc. p. 272.

Equiangular is alſo applied to any two figures of the ſame kind, when each angle of the one is equal to a correſponding angle in the other, whether each figure, ſeparately conſidered, be an equiangular figure or not, that is, having all its angles equal to each other. Thus, two triangles are equiangular to each other, if, *e. g.* one angle in each be of 30°, a ſecond angle in each of 50°, and the third angle of each equal to 100°.

Equiangular triangles have not their like ſides neceſſarily equal, but proportional to each other; and ſuch triangles are always ſimilar to each other.

EQUICRURAL Triangle, is what we more uſually call an iſoſceles triangle.

EQUICULUS, Equuleus, or *Equus minor*, in *Aſtronomy*, a conſtellation of the northern hemiſphere. See Equuleus.

EQUIDIFFERENT, in *Arithmetic*. If in a ſeries of three quantities there be the ſame difference between the firſt and ſecond as between the ſecond and third, they are ſaid to be continually equidifferent; but, if in a ſeries of four quantities, there be the ſame difference between the firſt and ſecond as between the third and fourth, they are ſaid to be diſcretely equidifferent.

Thus, 3, 6, 7, and 10, are diſcretely equidifferent, and 3, 6, and 9, continually equidifferent.

EQUIDISTANT, in *Geometry*, a term of relation between two things which are every where at an equal or the ſame diſtance from each other. Thus, parallel lines are ſaid to be equidiſtant, as they neither approach nor recede.

EQUILATERAL, of *æquus*, equal, and *latus*, ſide, is applied to any figure whoſe ſides are all equal. Thus, an equilateral triangle is that whoſe ſides are of equal length. In an equilateral triangle all the angles are likewiſe equal. See Equiangular.

All regular polygons and regular bodies are equilateral. See Polygon, Regular, &c.

Equilateral *Hyperbola*, is that in which the conjugate axes, and every pair of conjugate diameters, are equal to each other. The aſymptotes are alſo at right angles to each other, and each of them forms a right angle with the axis. Such an hyperbola is alſo equal to its oppoſite hyperbola, and likewiſe to its conjugate hyperbola, ſo that all the four conjugate hyperbolas are mutually equal to each other.

Hence, as the parameter is a third proportional to the conjugate axes, they are all mutually equal; conſequently, if in the equation for the hyperbola $y^2 = \frac{p}{t} \times \overline{tx + x^2}$, or $= \frac{c^2}{t^2} \times \overline{tx + x^2}$, in which t is the tranſverſe axis, c the conjugate, p the parameter, x the abſciſs, and y the ordinate, t, c, and p being made equal, the equation for the equilateral hyperbola becomes $y^2 = tx + x^2$; differing from that of the circle merely in the ſign of the term x^2, which in the circle is —. See Hyperbola.

EQUILIBRIUM, or Equipoise, in *Mechanics*, means an equality of forces acting in oppoſite directions, ſo that they mutually balance each other. Thus, the ſcales of a balance are ſaid to be in equilibrio, when neither of them preponderates, in conſequence of which the beam of the balance remains perfectly horizontal. But, it muſt not be imagined, that the equality of weights alone determines the equilibrium of mechaniſms in general; for that is only the caſe when the velocities and directions are equal, as in the above-mentioned caſe of the balance, where the two arms of the beam being equal, the weights in the ſcales have equal velocities, ſuppoſing that the balance is made to vibrate, and move in vertical directions. Therefore, it has been ſaid above, that the equilibrium takes place, when the *forces*, which act in oppoſite directions, are equal; for the forces are eſtimated from the weight of the bodies, their velocities, and directions conjointly. Thus, in the common mechanical powers, the equilibrium takes place, when the power is to the weight as the velocity of the weight is to the velocity of the power. The equlibrium of ſolids forms a conſiderable part of the ſcience of ſtatics, and the equilibrium of fluids forms a conſiderable part of hydroſtatics.

Equilibrium is alſo uſed figuratively on other occaſions. A painter muſt take care to obſerve the equilibrium of his figures, *i. e.* diſpoſe them well on their centre of gravity, that they may not ſeem ill-ſupported, or ready to tumble. Thus, *e. gr.* if one arm be moved forward, the other muſt be proportionably backward to poiſe the figure.

In a picture there ſhould always be an equilibrium between one part and another; that is, the objects are to be diſtributed ſo as to balance and contraſt each other; and not too many, *e. gr.* be crowded on one ſide, and the other be left bare.

EQUIMULTIPLE, in *Arithmetic* and *Geometry*, is applied to ſimple magnitudes when multiplied equally, *i. e.* by equal quantities or multipliers.

Thus, taking A as many times as B, or multiplying them equally, there will ſtill remain the ſame ratio between the magnitudes thus multiplied, as between the primitive magnitudes before multiplication.

Now thoſe magnitudes, thus equally multiplied, are called equimultiples of the original ones A and B; whence we ſay, that equimultiples have the ſame ratio as the ſimple quantities. In arithmetic, we generally uſe the term equimultiples for numbers which contain equally or an equal number of times their ſubmultiples.

Thus 12 and 6 are equimultiples of their ſubmultiples 4 and 2, inaſmuch as each of them contains its ſubmultiple three times.

EQUINA Sella. See Sella.

EQUINOCTIAL, in *Aſtronomy*, a great circle of the ſphere, under which the equator moves in its diurnal motion.

The equinoctial is conceived by ſuppoſing a ſemidiameter of the ſphere produced through a point of the equator, and there, by the rotation of the ſphere about its axis, deſcribing a circle on the immoveable ſurface of the primum mobile.

The poles of this circle are the poles of the world. The ſphere is divided by it into two equal parts, the northern and ſouthern. It interſects the horizon of any place in the eaſt and weſt points; and at the meridian its elevation above the horizon is equal to the co-latitude of the place.

Whenever the ſun, in his progreſs through the ecliptic, comes to this circle, it makes equal days and nights all around the globe; as he then riſes due eaſt and ſets due weſt, which he never does at any other time of the year. And hence the denomination from *æquus* and *nox*, night, *quia æquat diem nocti.* All the ſtars that are under this circle, or that have no declination, do alſo riſe due eaſt and ſet due weſt.

The equinoctial, then, is the circle which the ſun deſcribes, or appears to deſcribe, at the time of the equinoxes: that is, when the length of the day is every where equal to that of night, which happens twice a year. (See Equinox.) From this circle is the declination in the heavens or latitude of places on the earth counted in degrees of the meridian. Upon this circle is reckoned the longitude, 180° weſt and 180° eaſt, in all 360°. Hence, 1° of longitude anſwers to 4′ of time; 15′ to 1′ of time; and 1′ to 4 ſeconds of time, &c.

The ſhadows of thoſe who live under this circle are eaſt to the ſouthward of them for one-half of the year, and to the northward of them during the other half; and twice in a year, *viz.* at the equinoxes, the ſun at noon caſts no ſhadow, being in their zenith.

Equinoctial *colure*, is that paſſing through the equinoctial points. See Colure.

Equinoctial *dial*, is that whoſe plane lies parallel to the equinoctial. See Dial.

Equinoctial *hours*, *line*, *orient*. See the ſubſtantives.

Equinoctial *points*, are the two points wherein the equator and ecliptic interſect each other: the one, being in the firſt point of Aries, is called the vernal point, or equinox; and the other, in the firſt point of Libra, the autumnal point, or equinox.

The equinoctial points, and, indeed, all the other points of the ecliptic, are found, by obſervation, to be continually moving backwards, or in antecedentia, *i. e.* towards the weſt. This retrograde motion is called the *Preceſſion of the equinoxes*; which ſee.

EQUINOX, in *Aſtronomy*, the time when the ſun enters one of the equinoctial points.

The equinoxes happen when the ſun is in the equinoctial circle, of conſequence the days are equal to the nights throughout the world, which is the caſe twice a year, *viz.* about the 21ſt of March, and the 22d of September, the firſt of which is the vernal, and the ſecond the autumnal equinox.

As the ſun's motion is unequal, that is, ſometimes ſwifter and ſometimes ſlower (from the cauſes already explained under the article Equation), it comes to paſs, that there are about eight days more from the vernal to the autumnal equinox than from the autumnal to the vernal, the ſun ſpending ſo much more time in travelling through the northern than the ſouthern ſigns.

According to the obſervations of M. Caſſini, the ſun is $186^{d}\ 14^{h}\ 53'$ in the northern ſigns, and only $178^{d}\ 14^{h}\ 56'$ in the ſouthern. The difference of which is $7^{d}\ 23^{h}\ 57'$.

The ſun, continually advancing forwards in the ecliptic and gaining a degree every day, makes no ſtay in the equinoctial points, but the moment he arrives in them he alſo leaves them.

Of courſe, therefore, though the day the ſun enters the equinoctial point is called the equinox, as being reputed equal to the night; yet it is not preciſely ſo, unleſs the ſun enter the equator at mid-day: for if the ſun riſing, ſhould enter the vernal equinox at ſetting, he will have departed from it, and have got northwards about 12′; conſequently, that day will be ſomewhat longer than 12 hours, and the night proportionably ſhorter.

The time of the equinoxes, *i. e.* the moment in which the ſun enters the equator, is found by obſervation, the latitude of the place of the obſervation being given.

Thus, in the equinoctial day, or near it, take the juſt meridian altitude of the ſun; if this be equal to the altitude of the equator, or the complement of the latitude, the ſun is that very moment in the equator: if it be not equal, the difference is the ſun's declination. The next day obſerve the meridian altitude as before, and find his declination; if the declination be of different kinds, *viz.* the one north and the other ſouth, the equinox has happened in the interval of time between them; otherwiſe, the ſun has not entered the equinoctial, or had paſſed it at firſt. From theſe obſervations a trigonometrical calculus gives the time of the equinox.

Thus, let D G (*Plate* XII. *Aſtronomy*, *fig.* 110.) repreſent the equator, A C the ecliptic, E the equinoctial point; the points A, B, C, the places of the ſun at the times of obſervation; the arcs A D, B F, C G, the correſponding declinations; in the right-angled ſpherical triangles C E G, B E F, the obliquity of the ecliptic, and the declinations are known; whence may eaſily be found E C, E B; then B C, the ſum or difference of E C, E B is the ecliptic arc deſcribed in 24 hours: then ſay as B C : B E :: 24 hours for B C : time for B E; and this time ſhews the diſtance of the equinox from the time of the middle obſervation.

EQUINUS Barbatus, a kind of comet. See Hippeus.

Equinus *ellipticus* and *quadrangularis*. See Hippeus.

Equinus *venter*. See Venter *equi*.

EQUIP, *To*, in *Naval Language*, a term borrowed from the French marine, and frequently applied to the buſineſs of fitting a ſhip for ſea, or arming her for war. See Fitting-out.

EQUIPAGE, in *Navigation*. See Crew and Fitting-out.

Equipage, *Camp.* Under this term we confine ourſelves entirely to what relates to the tents generally in uſe; remarking, that ſuch as ſuit admirably for a cold climate, would be found totally unſerviceable in higher latitudes, where the air, confined in a ſmall ſpace, under a vertical ſun, while probably not a leaf is in motion, could not fail to be unfit for reſpiration. Therefore, we ſhall give the regulation ſizes of tents, both according to the home ſervice, and to what is found neceſſary for troops employed in the Eaſt Indies.

Home Service, Laboratory Tent, with mallets, poles, pins, &c. ſhould weigh 3 cwt. 24lb.; and ought to be ſuſtained on poles of 14½ feet each in length; the ridge pole ſhould be 18 feet. Some of theſe are made with half-walls; that is, their flies, or canopies, do not come within three feet of the ground, but are there faſtened to a half-wall, or curtain, which being laced or hooked to the interior of the fly, hangs perpendicularly to the ground, to which it is ſecured by wooden pins, or pegs.

India Service, Laboratory Tent.—This claſs of tents is nearly ſimilar, but they have commonly extra flies, ſtanding at about a yard diſtant from the inner ſhell, which are ſometimes well ſoaked in oil, or ſlightly with tar, at leaſt ſufficiently to throw off rain. This occaſions them to be extremely ponderous; the poles being ſome feet longer, and the ſpread of canvas conſiderably greater; the average weight of a laboratory tent may here be taken at nearly half a ton. Such a weight could only be conveyed on an elephant, or on a cart, (the latter being far too dilatory for moſt ſituations,) were it not that the fly, the ſhell, and the walls, are all made to ſeparate. By this means two camels may conveniently bear one of theſe tents.

Home Service, Bell Tent, ſhould, according to the new conſtruction, have a pole of 9 feet long, and form a circular ſpread of 14 feet in diameter, ſo as to give ſhelter to twelve men. Since it has been found neceſſary to reduce the quantity of baggage attached to our armies, little or no uſe is made of any tents that are inadequate to the ſhelter of a certain number of perſons; conſequently thoſe bell tents, which were called "Bells of Arms," have in a manner ceaſed to be known in our arſenals, they being totally incompetent to any eſſential ſervice. The modern bell tent is, therefore, to be conſidered as a medium between the bells of arms, and the private tents formerly in uſe; they are extremely portable, and, in proportion to their weight, which ought not to exceed 45lb. are far more ſerviceable; as they cover twelve men better than the common infantry tents, that weighed 27lb., did five. The facility with which a tent, having only a pole, is raiſed, or ſtruck, the great ſafety it inſures from preſenting no flat ſide to the wind, and the paucity of pins, &c. requiſite for its uſe, give it a very conſiderable claim to preference.

Indian Service, Bell Tents, are made of very ſtout canvas, ſupported on poles of about 7 feet in length, and overlapping in their front, for the purpoſe of keeping the arms they contain perfectly dry. The muſquets, &c. are filed round the pole of a bell tent by means of two ſticks, about 18 inches in length, paſſing at right angles to each other, and to the pole alſo, through two holes made in the latter. Theſe, which may be drawn at pleaſure, form a croſs, in the four diviſions of which the arms of the company are filed. Average weight, when dry, 1 cwt.; when wet, 1 cwt. 1 qr. 14lb.

Home Service, Common Infantry (or Private) Tents, which are now leſs uſed than formerly, require two ſtandard poles, each 6 feet in length, and a ridge pole of 7 feet. They ſhould weigh *in toto* 27lb., and be capable of covering five men. It is obvious, that a tent of this deſcription muſt be leſs ſafe, and leſs comfortable to its inhabitants, than the bell tent now ſubſtituted

Indian Service, Private Tents, ſtand upon two poles, each 9 feet long, and have a ridge pole of 8 feet. Theſe tents are made of very ſtrong canvas, and are ſometimes lined ſeparately; whereby they are rendered tolerably cool. They ſhould be capable of ſheltering twelve men commodiouſly; but in hot weather not more than eight ought to be allotted to one tent. Conſiderable relief is afforded by the walls of theſe tents; which are generally about 30 inches high. The average weight of one, complete, may be about 2 cwt. 1 qr. when dry; but when wet, it will perhaps exceed 4 cwt.

Home Service, Officer's Marquee, ſhould have two ſtandard poles, each 8 feet high, and a ridge pole of 7 feet: the total weight about 130lb. This kind of tent has walls about 4 feet in height, and is generally furniſhed with a ſeparate lining throughout.

Indian Service, Marquees, are upon a very different conſtruction. The proportions are as follows; *viz.*

	Length.	Breadth.	Ridge Poles.	Standard Poles.
Captain's marquee on two poles lined throughout with gingham, and having walls of 5 ft. 6in.	23 feet.	15 feet.	10 feet.	12 feet.
Subaltern's tent on 1 pole	14 feet.	14 feet.	——	11 feet.

Theſe proportions may ſeem very great, but they are found to be actually neceſſary in that climate. The total weight of a captain's marquee may be eſtimated, when dry, at 4 cwt.; when wet, at 6½ cwt. A ſubaltern's marquee, when dry, 3½ cwt.; and when wet, 5 cwt.

With reſpect to the larger claſſes of tents, ſuch as are uſed by our colonels and general officers, they approach ſomewhat towards the conſtruction of what, in the Indian ſervice, are called field officers' ſleeping tents, which generally have from 12 to 14 feet between two poles of 14 feet in height. They are chiefly compoſed of ſtrong ſhells made of Ruſſia-duck, with flies of canvas, and are ordinarily lined with perpet. The weight of ſuch a tent may be computed at 5 cwt. when dry; and when wet at 7¼ cwt. State tents may meaſure about 18 feet in the ridge, and have ſtandards of full 16 feet in height. Their poles are generally made in two pieces, joining in their centres by means of a cylinder of iron; on the ſame principle as the ſliding ferrils in ladies' paraſols.

We have thus given ſome inſight into the proportions between the tents appropriated to the ſeveral claſſes, ſo far as they could tend to inſtruct the reader; who will, of courſe, underſtand, that in proportion as the ſtandards of a tent are lengthened, ſo will the ſeveral ſlopes of the fly be lengthened in a ſuitable ratio. The ordinary computation is, that the direct depth of the ſlope ought to be two-thirds the length of the poles where a full wall is to be attached; four-fifths where a half-wall is to be furniſhed; and that the pole ſhould be one-quarter, or even a third, leſs in length than the direct ſlope of the fly is deep, if no walls whatever are to be added. The climate will indicate the neceſſity for more or leſs ſteepneſs in the ſlope; for if little rain falls, leſs declivity will anſwer; whereas, if, as in India, the rains are abundant and heavy, ſuch a ſlope muſt be given as may inſure that the interior ſhould remain dry.

It is of the utmoſt importance, that all camp equipage ſhould be made not only conformably to a particular pattern, thereby to preſerve uniformity of appearance; but, as nearly as practicable, of the ſame kind of materials, and of a given weight; ſo that a very correct eſtimate may be formed both of the bulk and gravity of the whole, when about to be conveyed either by land or by water. Beſides, it is expedient, that the camp-colourmen, batmen, &c. ſhould have a perfect underſtanding of this branch of military economy, and have the whole of the tents handed to them, when about to be laden, or conveyed, packed in a regular manner; ſo as to occupy as little ſpace as poſſible; otherwiſe they never can ſtow to advantage, ſo as to be ſafe, and to afford as much ſpace as can be ſpared for other articles.

Equipage, in the *Military Art*, denotes all ſorts of utenſils, artillery, &c. neceſſary for commencing and proſecuting with eaſe and ſucceſs any military operations.

EQUIPOLLENCE, in *Logic*, is when there is an equivalence between any two or more terms or propoſitions; *i. e.* when they ſignify one and the ſame thing, though they expreſs it differently. Such propoſitions, &c. are ſaid to be equipollent.

EQUIPPE', in *Heraldry*, expreſſes a cavalier equipped, *i. e.* armed at all points.

EQUIRIA, in *Antiquity*, a feſtival inſtituted by Romulus, and celebrated on the 27th of February, in honour of Mars, at which there were horſe-races.

EQUISELIS, in *Natural Hiſtory*, the name of a large fly, of the ſize of a hornet, but having only two wings and no ſting: it otherwiſe much reſembles the common hornet in ſhape. This fly is found only in Macedonia. We have alſo in England flies which nearly reſemble the hornet, waſp, and bee, but in their wanting ſtings and having only two wings.

Equiselis, in *Ichthyology*, a name uſed by ſome authors for a ſea-fiſh, caught on the Spaniſh ſhores, and ſuppoſed by many to be the ſame with the *Dorado*, or *Coryphæna*, with the forked tail of Artedi. See Coryphæna.

EQUISETUM, in *Botany*, from *equus*, a horſe, and *ſeta*, a ſtrong hair or briſtle. Horſetail. Plin. Hiſt. Nat. lib. 26. cap 13. Linn. Gen. 559. Schreb. 753. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1102. Hedwig. Theor. 33. t. 1, 2. Juſſ. 17. Claſs and order, *Cryptogamia Filices.* Linn. *Cryptogamia Miſcellaneæ.* Schreb. Nat. Ord. *Filices ſpicatæ.*

Gen. Ch. *Fructifications* in an ovate-oblong terminal catkin, compoſed of whorled, ſtalked ſcales. Each ſcale peltate, ſomewhat orbicular, but with many ſides, bearing on its under ſide from four to ſeven tubular, angular, obtuſe ſheaths, parallel to and ſurrounding the ſtalk of two valves, burſting internally, containing numerous florets. *Stam.* Filaments four, coiled up round the germen, in a ſpiral manner, while moiſt, divaricated when dry; anthers terminal, ſimple, ſpatulate. *Piſt.* Germen globoſe, wrapped up in the ſtamens; ſtyle none; ſtigma obſolete, acute. *Seeds* globoſe, deciduous, accompanied by the ſtamens.

Eſſ. Ch. Catkin with peltate ſcales, fructifying on their inſide. Partial involucrums tubular, of two valves. Seeds numerous, naked, ſurrounded by four ſpiral ſtamens.

Many different opinions have exiſted concerning the fructification of this genus, but Hedwig's, as above given, ſeems to us the moſt ſatisfactory. In the artificial claſſification we retain it among the ferns, to which it is cloſely allied in natural affinity, though of itſelf a moſt natural and diſtinct genus; nor do we think Schreber's order, entitled *Miſcellaneæ*, leſſens in any degree the difficulties reſpecting this tribe.

Seven ſpecies of *Equiſetum* are found in Britain, and two or three foreign ones are imperfectly known beſides.

E. *ſylvaticum*, Engl. Bot. t. 1874, known by its compound drooping branches, is one of the pretrieſt. It occurs chiefly in mountainous countries, in moiſt, ſhady ſpots.

E. *hyemale*, Engl. Bot. t. 915, called Shave-graſs or Dutch ruſh, is remarkable for the callous roughneſs of the ribs of its naked ſtem, which renders it uſeful in poliſhing wood, ivory, and even braſs. Being rare in England, it has for theſe purpoſes been imported from Holland. Profeſſor Davy has detected a large proportion of flinty earth in the cuticle, to which its hardneſs and aſperity are owing.

E. *variegatum*, Engl. Bot. t. 1987, found on the ſandy ſea-coaſt of Scotland, by Mr. G. Don, and a native alſo of Sweden, Denmark, Switzerland, &c. is a ſmaller ſpecies, nearly related to the laſt, and having a ſimilar roughneſs.

Equisetum, in *Natural Hiſtory*, is the name by which ſome writers have denominated certain foſſil plants, (phytolithii,) which are found bearing ſome faint reſemblance to the recent plant called horſe-tail. Mr. William Martin, after deſcribing an organic remain of this kind in his "Petrificata Derbienſia," ſays, "there are other plants with ſtellate leaves, to which it might with as much propriety be referred: hippuris, aſperiala, and galium, for inſtance," and he continues, "we may here obſerve, that little has yet been done with reſpect to diſcriminating the original genera of foſſil plants: thoſe parts indeed, on which ſuch diſcrimination *muſt* be founded, are rarely, if ever, viſible in the petrified ſtate. The characteriſtic diſtinctions of the ſpecies are frequently attainable, if ſtudiouſly ſought after, by a diligent and careful compariſon of various ſpecimens; and the habit or general appearance of the foſſil often leads to the knowledge of the natural claſs and order of the recent plant: but its genus, for the moſt part, remains undetermined or doubtful." The great importance of the organic remains or *reliquia* in tracing and identifying the ſtrata, according to the new diſcoveries of Mr. Smith and his pupils, will, it is hoped, ere long, induce naturaliſts ſeriouſly to turn their attention to this neglected branch of ſcience.

EQUISONANCE, in *Muſic*, a name by which the ancients diſtinguiſhed octaves from other concords. Octaves being the only *paraphoni*, or concords, when doubled above or below. This is a diſtinction which would be as uſeful in modern muſic as in the ancient. All other concords, doubled, become diſcords.

EQUITANTIA, Folia, in *Botany*, is applied to leaves ſo folded at the baſe, as to embrace each other in two ranks. See Leaf.

EQUITATA Cohors, in *Antiquity*. See Cohors *Equitata.*

EQUITY, Æquitas, denotes juſtice or right, mitigated and tempered by the conſideration of particular circumſtances; or a correction and abatement of the ſeverity of ſome law; or a temperament, which, without being unjuſt, abates the rigour of ſome juſt law.

Equity, as Grotius defines it, is the correction of that, wherein the law (by reaſon of its univerſality) is deficient. For ſince in law all caſes cannot be foreſeen or expreſſed, it is neceſſary, that when the general decrees of the law come to be applied to particular caſes, there ſhould be ſomewhere a power veſted of defining thoſe circumſtances, which (had they been foreſeen) the legiſlator himſelf would have expreſſed. And theſe are the caſes which, according to Grotius, "lex non exacté definit, ſed arbitrio boni viri permittit."

This is what the Greeks call επιεικεια. The utmoſt ſeverity of a good law is frequently contrary to juſtice; it ſhould always have equity for its rule and guide. "Summum jus, ſæpe ſumma injuria."

The foundation of equity is not that there is any miſtake in the law, but that the law was laid down univerſally, becauſe all circumſtances could not be conſidered or taken in under one law.

For an inſtance, ſuppoſe it an expreſs law, that the city being now beſet with an enemy, the gates be all ſhut; and ſuppoſe it fall out that the enemy is then in purſuit after ſome of the citizens by whom it is defended, ſo that it would be highly prejudicial thereto not to open for them the gates; equity here decrees the gates to be opened, contrary to the expreſs words of the law.

As equity depends, eſſentially, upon the particular circumſtances of each individual caſe, there can be no eſtabliſhed rules and fixed precepts of equity laid down, without deſtroying its very eſſence, and reducing it to a poſitive law. And, on the other hand, the liberty of conſidering all caſes in an equitable light, muſt not be indulged too far; leſt we thereby deſtroy all law, and leave the deciſion of every queſtion entirely in the breaſt of the judge. And law, without equity, though hard and diſagreeable, is much more deſirable for the public good, than equity without law; which would make every judge a legiſlator, and introduce infinite confuſion, as there would then be almoſt as many different rules of action laid down in our courts, as there are differences of capacity and ſentiment in the human mind.

Equity is of two kinds, and thoſe of contrary effects; the one abridges, and takes from the letter of the law; and the other enlarges, and adds to it.

The firſt is defined the correction of a law, made generally in that part wherein it fails; as ſuppoſe a ſtatute made, "that whoſoever does ſuch a thing ſhall be a felon, or ſuffer death:" yet if a mad-man, or an infant, who hath no diſcretion, do the ſame, he ſhall neither be a felon nor ſuffer death.

The other is defined an extenſion of the words of the law to caſes which are not expreſſed, which yet come under the ſame reaſon: ſo that when one thing is enacted, all other things which are of the like degree are ſo too.

Thus, the ſtatute which ordains, that in action of debt againſt executors, he who appears by diſtreſs ſhall anſwer, extends by equity to adminiſtrators; and ſuch of them as ſhall appear firſt by diſtreſs, ſhall anſwer by the equity of the ſaid act, "quia ſunt in æquali genere."

Equity is alſo uſed for the virtue of juſtice. See Justice.

Equity, in our *Laws*, &c. is alſo frequently uſed for the Court *of Chancery*, (which ſee,) where controverſies are ſuppoſed to be determined according to the exact rules of equity and conſcience, by mitigating the rigour of the common law.

"Æquitas ſequitur legem," is an old maxim in law; but, from the great increaſe of ſuits in chancery, ſome have thought fit to give it this conſtruction, that in all caſes after a man has been at law, he muſt go to equity.

Judge Blackſtone has given a brief, but comprehenſive view of the nature of equity, as it is now underſtood and practiſed in our ſeveral courts of judicature. Equity, he ſays, in its true and genuine meaning, is the ſoul and ſpirit of all law; *poſitive* law is conſtrued, and *rational* law is made by it. In this, equity is ſynonymous to juſtice: in that, to the true ſenſe and ſound interpretation of the rule. But the very terms of a court of *equity*, and a court of *law*, as contraſted to each other, are apt to confound and miſlead us; as if the one judged without equity, and the other was not bound by any law. Whereas every definition or illuſtration to be met with, which now draws a line between the two juriſdictions, by ſetting law and equity in oppoſition to each other, will be found either totally erroneous, or erroneous to a certain degree. Thus, in the *firſt* place, it is ſaid, that it is the buſineſs of a court of equity in England to abate the rigour of the common law; but no ſuch power is contended for. The learned judge ſpecifies various caſes of poſitive law, in which the court of equity can give no relief, and in which theſe, as well as the courts of law, muſt ſay with Ulpian, "hoc quidem perquam durum eſt, ſed ita lex ſcripta eſt." Again it is ſaid, that a court of equity determines according to the ſpirit of the rule, and not according to the ſtrictneſs of the letter: but ſo alſo does a court of law. Both, for inſtance, are equally bound, and equally profeſs, to interpret ſtatutes according to the true intent of the legiſlature. In general laws, all caſes cannot be foreſeen; or, if foreſeen, cannot be expreſſed: ſome occur that will fall within the meaning, though not within the words of the legiſlator; and others, which may fall within the letter, may be contrary to his meaning, though not expreſsly excepted. Theſe caſes, thus out of the letter, are often ſaid to be within the equity of an act of parliament; and ſo caſes within the letter are frequently out of the equity. Here by equity we mean nothing but the ſound interpretation of the law; though the words of the law itſelf may be too general, too ſpecial, or otherwiſe inaccurate or defective. Theſe are the caſes to which Grotius refers in the paſſage cited above. But there is not a ſingle rule of interpreting laws, whether equitably or ſtrictly, that is not equally uſed by the judges in the courts both of law and equity; the conſtruction muſt in both be the ſame, or, if they differ, it is only as one court of law may alſo happen to differ from another, each endeavours to fix and adopt the true ſenſe of the law in queſtion: neither can enlarge, diminiſh, or alter that ſenſe in a ſingle tittle.

It has been further ſaid, that *fraud*, *accident*, and *truſt*, are the proper and peculiar objects of a court of equity. But every kind of *fraud* is equally cognizable, and equally adverted to, in a court of law. Many *accidents* are alſo ſupplied in a court of law. And, although a technical *truſt*, created by the limitation of a ſecond uſe, was forced into the courts of equity; and this ſpecies of truſts, extended by inference and conſtruction, has ever ſince remained as a kind of *peculium* in theſe courts; yet there are other truſts which are cognizable in a court of law. Moreover, it has been ſaid that a court of equity is not bound by rules or precedents, but acts from the opinion of the judge, founded on the circumſtances of every particular caſe. Whereas the ſyſtem of our courts of equity is a laboured, connected ſyſtem, governed by eſtabliſhed rules, and bound down by precedents, from which they do not depart, although the reaſon of ſome of them may perhaps be liable to objection.

In ſhort, if a court of equity in England did really act, as many ingenious writers have ſuppoſed it (from theory) to do, it would riſe above all law, either common or ſtatute, and be a moſt arbitrary legiſlator in every particular caſe. Formerly, indeed, our courts of equity arrogated to themſelves ſuch an unlimited authority as hath totally been diſclaimed by their ſucceſſors for more than a century paſt. But the ſyſtems of juriſprudence, in our courts, both of law and equity, are now equally artificial ſyſtems, founded in the ſame principles of juſtice and poſitive law; but varied by different uſages in the forms and mode of their proceedings; the one being originally derived (though much reformed and improved) from the feudal cuſtoms, as they prevailed in different ages in the Saxon and Norman judicatures; the other (but with equal improvements) from the imperial and pontifical formularies, introduced by their clerical chancellors.

The ſuggeſtion indeed of every bill, to give juriſdiction to the courts of equity (copied from thoſe early times) is, that the complainant hath no remedy at the common law. But he, who ſhould from thence conclude, that no caſe is judged of in equity, when the law might have given relief, and, at the ſame time, caſts his eye on the extent and variety of the caſes in our equity reports, muſt think the law a dead letter indeed. The rules of property, rules of evidence, and rules of interpretation, in both courts, are, or ſhould be, exactly the ſame; both ought to adopt the beſt, or muſt ceaſe to be courts of juſtice. Neither a court of equity nor of law can vary men's wills or agreements, or (in other words) make wills or agreements for them. Both are to underſtand them truly, and therefore both of them uniformly. The rules of deciſion are in both courts equally appoſite to the ſubjects of which they take cognizance. Such then being the parity of law and reaſon which governs both ſpecies of courts, it may be aſked what conſtitutes their eſſential difference? It principally conſiſts in the different modes of adminiſtering juſtice in each; in the mode of proof, the mode of trial, and the mode of relief. Upon theſe, and upon two other accidental grounds of juriſdiction, which were formerly driven into theſe courts by narrow deciſions of the courts of law, *viz.* the true conſtruction of ſecurities for money lent, and the form and effect of a truſt or ſecond uſe; upon theſe main pillars hath been gradually erected that ſtructure of juriſprudence which prevails in our courts of equity, and is inwardly bottomed upon the ſame ſubſtantial foundations as the whole ſyſtem of law. As to the mode of proof, when facts, or their leading circumſtances, reſt only in the knowledge of the party, a court of equity applies itſelf to his conſcience, and purges him upon oath with regard to the truth of the tranſaction; and, that being once diſcovered, the judgment is the ſame in equity as it would have been at law. But, for want of this diſcovery at law, the courts of equity have acquired a concurrent juriſdiction with every other court in all matters of account. From this compulſive diſcovery upon oath, the courts of equity have acquired a juriſdiction over all matters of fraud. As to the mode of trial, this is by interrogations adminiſtered to the witneſſes, upon which their depoſitions are taken in writing, wherever they happen to reſide. With reſpect to the mode of relief, the want of a more ſpecific remedy, than can be obtained in the courts of law, gives a concurrent juriſdiction to a court of equity in a great variety of caſes. Thus it is in executory agreements, and in various kinds of frauds, &c. The true conſtruction of ſecurities for money lent is another fountain of juriſdiction in courts of equity. The form of a truſt, or ſecond uſe, gives the courts of equity an excluſive juriſdiction as to the ſubject-matter of all ſettlements and deviſes in that form, and of all the law terms created in the preſent complicated mode of conveyancing. This is a very ample ſource of juriſdiction. Blackſt. Com. vol. iii.

Equity *of redemption*, on mortgages, is that right which a mortgagor has of redeeming his eſtate upon payment of the money borrowed. This enables a mortgagor to call on the mortgagee who has poſſeſſion of his eſtate to deliver it back, and account for the rents and profits received, on payment of his whole debt and intereſt; thereby turning the *mortuum* into a kind of *vivum vadium*. But on the other hand, the mortgagee may either compel the ſale of the eſtate in order to get the whole of his money immediately, or elſe call upon the mortgagor to redeem his eſtate preſently, or, in default thereof, to be for ever foreclosed from redeeming the ſame, that is, to loſe his equity of redemption without poſſibility of recall. And alſo in ſome caſes of fraudulent mortgages, (ſtat. 4 & 5 W. & M. c. 16.) the fraudulent mortgagor forfeits all equity of redemption whatſoever. This is done by proceedings in the court of chancery. But the chancery cannot ſhorten the time of payment of the mortgage money, where it is limited by expreſs covenant, though it may lengthen it; and then upon non-payment, the practice is to foreclose the equity of redemption of the mortgagor. 2 Vent. 364.

To foreclose the equity, a bill in chancery is exhibited, to which an anſwer is put in, and a decree being obtained, a maſter in chancery is to certify what is due for principal, intereſt, and coſts, which are to be prefixed by the decree, whereupon the premiſes are to be re-conveyed to the mortgagor; or, in default of payment, the mortgagor is ordered to be foreclosed from all equity of redemption, and to convey the premiſes abſolutely to the mortgagee. Law of Securities, p. 129. 133.

By ſtat. 7 Geo. II. cap. 20, after payment or tender by the mortgagor of principal, intereſt, and coſts, the mortgagee can maintain no ejectment, but may be compelled to re-aſſign his ſecurities.

Equity, in *Mythology*, ſometimes confounded with Juſtice, a goddeſs among the Greeks and Romans, repreſented with a ſword in one hand and a balance in the other.

EQUIVALENT, is underſtood of ſomething that is equal in value, force, or effect, to another.

Equivalence is of various kinds, in propoſitions, in terms, and in things.

Equivalent *propoſitions*. See Equipollence.

Equivalent *terms*, are where ſeveral words that differ in ſound have yet one and the ſame ſignification; as "every body was there," and "nobody was abſent," *nihil non*, and *omne*.

Equivalent *things*, are either moral, phyſical, or ſtatical. Moral, as when we ſay that the commanding or adviſing a murder is a guilt equivalent to that of the murderer. Phyſical, as when a man who has the ſtrength of two men is ſaid to be equivalent to two men. Statical, whereby a leſs weight becomes of equal force with a greater, by having its diſtance from the centre increaſed.

EQUIVOCAL, Equivocum, denotes a word or expreſſion that is dubious and ambiguous, or that may have ſeveral ſenſes, one true and another falſe.

Equivocal terms anſwer to what are otherwiſe called *homonyma*, or homonymous terms.

Such is the word *emperor*, which is both the name of a dignity, the proper name of a perſon, and the name of a plant. So alſo the Latin *gallus*, which ſtands indifferently for a cock and a Frenchman.

In theſe caſes, one word denotes two or more different ideas, or different ſorts of objects: whence that common definition of equivocals in the ſchools, "quorum nomen eſt commune ratio vero eſſentiæ ſecundum illud nomen diverſa." Philoſophers diſtinguiſh equivocals into active and paſſive; or æquivoca æquivocantia, and æquivocata.

Æquivoca æquivocantia, or thoſe that denominate and ſignify things, are words common to ſeveral things in a very different ſignification, *i.e.* to ſeveral things which have a ſimilar eſſence correſpondent to the ſimilar denominations. *E.gr.* The word *taurus*, which ſtands for a ſign, a mountain, and an animal; and in one ſignifies a lowing animal; in another, a heap of ſtones and earth; and in the third, a conſtellation or ſyſtem of ſtars.

Æquivoca æquivocata, or thoſe that are called or denominated, are the things ſignified by ambiguous names, *e. gr.* a ſign, a mountain, and an animal; which laſt ſpecies of equivocals alone Ariſtotle ſeems to have had in view in his definition, which agrees to theſe, and theſe only.

Equivocal *action and cauſe.* See Action and Cause.

Equivocal *generation*, is a method whereby animals and plants are ſuppoſed to be produced, not by the uſual way of coition between male and female, but by ſome ſuppoſed plaſtic power or virtue in the ſun, &c.

Thus, inſects, maggots, flies, ſpiders, frogs, &c. have uſually been ſuppoſed to be produced by the heat of the ſun warming, agitating, and impregnating the duſt, earth, mud, and putrified parts of animals.

This method of generation, which we alſo call *ſpontaneous*, was commonly aſſerted and believed among the ancient philoſophers; but the moderns, from more and better obſervations, unanimouſly reject it, and hold that all animals, nay, and vegetables too, are univocally produced; that is, from parent animals, and vegetables of the ſame ſpecies and denomination.

It were a thing, one would imagine, ſufficient to diſcredit the Ariſtotelian, or rather the Egyptian doctrine of equivocal generation, to find flies, frogs, lice, &c. to be male and female, and accordingly to ingender, lay eggs, &c.

The doctrine of equivocal generation we call an *Egyptian doctrine*, as having, in all probability, had its riſe in Egypt, to ſolve the hypotheſis of the original production of men, and other animals, out of the earth, by the help of the ſun's heat.

To prove which, the Egyptians, as Diodorus Siculus obſerves, produce this obſervation, that about Thebes, when the earth is moiſtened by the Nile, and afterwards impregnated by the intenſe heat of the ſolar rays, an innumerable ſwarm of mice come forth: whence he infers, that all kinds of animals might equally have ariſen out of the earth at the beginning of things; and from theſe biſhop Stillingfleet takes the other writers and adherents to the doctrine of equivocal generation, Mela, Pliny, Ovid, &c. to have borrowed the hypotheſis without inquiring into its truth. Derham's Phyſ. Theol. lib. iv. cap. 15. See Generation.

EQUIVOCATION, Æquivocatio, the uſing a term or expreſſion that has a double ſignification.

Equivocations are expedients to ſave telling the truth; and yet without telling a falſity. The fathers are great patrons of equivocations and mental reſervations, holding, that the uſe of ſuch ſhifts and ambiguities is in many caſes allowable.

St. Auguſtine, particularly, is reproached with endeavouring to vindicate Iſaac for ſaving his wife from a crime by an equivocation; "tacuit aliquid veri, & non dixit aliquid falſi." To advance a dubious propoſition, knowing it will be underſtood in a ſenſe different from that you give it in your mind, is an equivocation, and a breach of good faith and ſincerity.

In moral theology, it is ſtrictly underſtood of a term or phraſe with two different ſignifications, the common and obvious, the other more unuſual and remote; the latter of which being underſtood by the ſpeaker, but the former by the hearers, they conceive ſomething different from one another.

Of this we have an inſtance in St. John, chap. xi. where our Saviour is repreſented as ſaying, "Lazarus ſleepeth," for the diſciples who took the word ſleeping in the uſual ſignification, concluded that Lazarus, whom they had been told, was ſick, began to take reſt, and would ſoon recover; but Jeſus, uſing the word in a leſs direct and uſual ſignification, meant that Lazarus was dead.

When the equivoque conſiſts of ſeveral words, it is properly called an *amphibology*, (which ſee,) of which we have an inſtance in St. John, chap. ii. "Deſtroy this temple," ſays Jeſus, ſpeaking to the Jews, "and I will raiſe it again in three days."

The lawfulneſs of the uſe of equivocations has been greatly diſputed among the modern caſuiſts; many grave authors deny that it is allowable to uſe them on any occaſion whatever. Their reaſon is, that an equivoque is to all intents and purpoſes the ſame thing with a lie.

EQUIVOQUE, L', in *Muſic*, is when a ſharp, by extraneous modulation, becomes a flat, and *è contra*. As the chord of D♭ becoming the chord of C♯ with a ſharp 3d, &c. See Modulation, and Extraneous.

EQUULEUS, or Eculeus, in *Antiquity*, a kind of rack, or engine of torture, uſed for extorting the truth; at firſt chiefly on ſlaves, but afterwards turned againſt the Chriſtians.

The patient's arms and legs being faſtened on the equuleus with cords, he was hoiſted aloft, and extended in ſuch manner that all his bones were diſlocated. In this ſtate, red-hot plates were applied to his body, and he was alſo goaded in the ſides with an iron-forked inſtrument, called *ungula*.

The equuleus was of wood, and had holes at certain diſtances, with a ſcrew, by which the criminal was ſtretched to the third, ſometimes to the fourth or the fifth hole: at intervals, the ſcrew was ſlackened again, by which he had ſome reſpite; but then he was tormented with queſtions.

The equuleus in more ancient times was conſtructed in the form of a horſe; the criminal was laid on his back, and his arms were turned under the breaſt of the equuleus, his hands were bound, and his feet ſtretched out towards his tail. A rope faſtened to the feet was made to paſs over a ſmaller pulley between the hind-legs of the equuleus, and made to coil over another larger pulley fixed under the belly by means of a handle, which the executioner turned round till all the bones, &c. were diſlocated. See a learned diſſertation on the form and uſe of this inſtrument, by Dr. Ward, in the Phil. Tranſ. vol. viii. part iv. p. 32, &c.

Hieronymus Magius, when a priſoner among the Turks, wrote an expreſs treatiſe "De Equuleo;" and another of Bells, merely as it is ſaid from his memory, without any aſſiſtance of books. Sigonius had another treatiſe on the ſame ſubject.

Equuleus, *Equiculus*, and *Equus minor*, *equi ſectio*, the *Horſe's Head*, in *Aſtronomy*, a conſtellation of the northern hemiſphere, whoſe ſtars in Ptolemy's Catalogue are 4, in Tycho's 4, in Hevelius's 6, and in Mr. Flamſteed's 10. See Constellation.

Equuleus, in *Arts* and *Manufactures*. See Horse.

EQUUS, in *Zoology*, a genus of the Belluæ order. The fore-teeth in the upper jaw are ſix, erect, and parallel; the lower ſix, and more prominent; tuſks ſolitary, included, remote; teats two, inguinal.

Species.

Caballus. Tail with long flowing hair. *Equus cauda undique ſetoſa*, Linn. *Equus auriculus brevibus erectis, juba longa*, Briſſ. Ἵππος. Ariſtot. Ælian, &c. *Equus, equa, equiferus*, Pliny. Geſn. Aldr. &c. *Cheval*, Buff. *Roſs*, Geſn. *Horſe.*

Ferus. α. *equus ferus*, Haſſelq. *Wilde Pferde*, Gmel. Pallas. *Tarpany*, Rytſchk. Orenb. *Wild horſes*, Bell.

Domesticus. β. *equus domeſticus*. *Domeſtic horſe.*

This generous animal is cultivated in moſt parts of the earth, and is found in a wild ſtate in the deſerts of Great Tartary, in the ſouthern parts of Siberia, the banks of the river Don, and other parts of Aſia and Africa. See Horse.

Hemionus. Longitudinal dorſal ſtripe without humeral tranſverſe band; tail hairy at the tip only. *Equus hemionus*, Pallas Nov. Comm. Petrop. v. 19. Gmel. *Czigitai*, Buff.

This curious animal, deſcribed by Pallas in the Tranſactions of the Royal Academy of Peterſburgh, is ſuppoſed by that naturaliſt to be the hemionos of Ariſtotle, and which appears, if this conjecture be correct, to have remained almoſt unnoticed from the time of Pliny, who mentions it as a native of Cappadocia.

The *Czigitai*, or, as more commonly called, *Dſhiggetéi* in the Mongolian language, is a native of the deſert regions between the rivers Onon and Argun, in the ſouthern parts of Siberia, and eſpecially thoſe of Gobi, which extend even to the confines of China and Thibet. The name *Dſhiggetéi* ſignifies *Great Ears*, and is given to this ſpecies of wild horſe, becauſe its ears exceed in proportion the ſize of thoſe of the common kind. They are, nevertheleſs, ſtraighter and better formed than thoſe of the mule, to which the whole conformation of the animal bears much ſimilitude. His ſtature is that of a mule of the common dimenſions: the length being more than five feet, and his weight from four to five hundred pounds. The head is large, with an appearance of heavineſs, and the front flattened: the eyes moderate, with aſh-coloured irides. The mouth is furniſhed with thirty-four teeth. The neck is ſlender, and compreſſed with a ſoft, ſhort, erect mane, and on the fore-top a tuft of downy hair about two inches in length. The body is rather long; the breaſt large and protuberant; the back ſomewhat concave or depreſſed, with the flanks and poſterior part thin, as in the mule. The limbs are long and ſlender, with an oval callus within the fore legs; the hoofs like thoſe of the aſs; and the tail, which is two feet in length, correſponding with that of the cow, in being naked for half its length, and having the tip hairy.

During ſummer the prevailing colour of this animal is yellowiſh brown, with the upper part of the head and inner part of the limbs tawny, and ſometimes the inſide of the hind thighs and belly are ſaid to be whitiſh. The noſe is white; the mane and tail blackiſh; and the back marked with a line of cheſnut or deep black, extending from the mane to the tail. The dorſal line is rather dilated on the loins, and becomes narrower towards the tail. The ſummer coat is much ſmoother than that which it aſſumes in winter, for the hair during the latter ſeaſon is longer, and changes to a deeper or more ruddy hue, inclining at the tips to grey.

Theſe animals are of a ſocial diſpoſition among themſelves, living together in troops of twenty or thirty, or ſometimes an hundred. They prefer the open plains, abounding in ſalt marſhes; and never approach the foreſts nor mountainous ſituations. Each of thoſe troops is placed under the guidance of a leader, who is conſtantly on the watch while the reſt of the herd is at reſt, or feeding; and who, in caſe of danger, gives the ſignal of alarm, by leaping and looking ſteadfaſtly at the object which excites his fears. This vigilant leader is often killed, becauſe he is ſtationed at ſome diſtance from the herd, and oftentimes approaches ſtill nearer to the hunters, in order to watch them attentively; and when he falls the herd does not diſperſe till many of them are killed. When alarmed and put to flight the beſt horſes could not overtake them; their ſwiftneſs ſurpaſſes that even of the antelopes. They have the ſenſes of ſight and ſmell in exquiſite perfection In their manners they are naturally timid, but when cloſely preſſed by an enemy are very fierce, and defend themſelves both with their teeth and feet. Their neigh is more ſhrill than that of a horſe. The pregnant females are with young from Auguſt till the following ſpring, when each produces a foal, or rarely two.

The Czigitais would form an excellent race of ſmall horſes, could they be reduced to a ſtate of domeſtication, but ſuch is the untractableneſs of their diſpoſition, that the difficulties of training them for this purpoſe appear unſurmountable. The people of the vaſt deſerts which they inhabit purſue them only for the ſake of their fleſh and ſkin, the former of which they eſteem a delicacy.

Asinus. Tail briſtly at the extremity; a black croſs on the ſhoulders. Linn. The Aſs.

This animal is deſcribed at length under the article Asinus.

Zebra. Body pale buff, with perpendicular fuſcous bands; limbs tranſverſely ſtriped with fuſcous. *Equus zebra, faſciis fuſcis verſicolor*, Linn. *Equus indicus*, Jonſt. *Equus braſilienſis*, Jacob. *Zecora*, Ludolf. *Aſne de beauté extraordinaire*, Thevenot. *Indianiſch Maulthier*, Geſn.

The zebra is one of the moſt beautiful quadrupeds known; uniting to the grace of the horſe, and ſwiftneſs of the ſtag, a peculiar combination of colours, that renders its appearance admirable. This animal is rather larger than the common aſs, and bears ſome reſemblance to the mule. The head is of moderate ſize, and well formed, the ears long, the legs delicate, the body graceful, and the beauty of its ſhape heightened by the ſmoothneſs of the ſkin. The colour is either milk white, or faintly tinged with brown, or pale ferruginous, and the whole animal adorned with alternate pale and fuſcous bands diſpoſed with ſuch amazing regularity as to have rather the appearance of art than nature. The ſtripes run in a tranſverſe direction both on the body and limbs. The head is ſtriped with fine bands of black and whitiſh, forming a centre in the forehead. The neck is adorned with ſtripes of the ſame, running in the ſame direction as thoſe on the back, all which point perpendicularly towards the belly. The thighs and legs are faſciated tranſverſely with fuſcous. The tail is of moderate length, round, rather ſlender, marked with blackiſh bands, and terminated by a thick tuft of browniſh hair. The colours in the male are remarkably vivid, being ſometimes of a fine yellow or yellowiſh, with the ſtripes nearly black, the female is almoſt white, with the ſtripes brown.

Theſe animals are found in the hotter regions of Africa, from Ethiopia to the Cape of Good Hope; and are in particular met with in great plenty in the extenſive ſolitary mountainous waſtes of the latter tract of country. They live in large herds, and poſſeſs much of the manners both of the horſe and the aſs, are exceſſively ſwift and vigilant, and prefer ſubſiſting on the hard and dry herbage their ſterile haunts afford, to deſcending into the more fertile and more frequented plains. The diſpoſition of the zebra is more unmanageable than that either of the horſe or aſs; and even ſuch as have been taken when very young have evinced the ſame invincible degree of paſſion for liberty, when grown up, as thoſe caught at an age of maturity. The Dutch have taken great pains to train them for domeſtic purpoſes, but with little ſucceſs, and which is the more to be regretted as the domeſtication of theſe animals would be of eſſential utility to the colony. This is teſtified from the actual obſervations of many travellers.

The zebra, tranſported into the temperate climates of Europe, have been known to produce young; but their offſpring degenerates. It has been known to couple with the Arabian horſe, and to give birth to a ſmall mule not very unlike the hybrid creature formed between the horſe and aſs. According to Sparrmann, the zebra is hunted by the Hottentots for the ſake of its fleſh, which they deem excellent; but, in reality, it is in no reſpect ſuperior to that of the horſe. Le Vaillant deſcribes the manners of theſe animals: the cry of the zebra, according to this writer, is very ſingular.

Quagga. Above cheſnut faſciated with fuſcous, ſides ſpotted; belly, legs, and thighs white. *Equus quagga*, Gmel. *Opeagha*, or *quagga*, of the Hottentots. Maſſon's Travels, Phil. Tranſ.

The quagga approaches ſo nearly in reſemblance to the zebra, as to have remained till very lately confounded with it, and from various circumſtances to be conſidered as the female. This animal is inferior in ſize to the zebra. The prevailing colour reddiſh brown, and the upper part is marked with bands of black, but one of the principal differences conſiſts in the belly, legs, and thighs being white, and deſtitute of bands, as are alſo the flanks and buttocks. There is an obvious diſtinction between the two ſexes of this animal, the colours of the male being far more vivid than thoſe of the female.

The more ſolitary regions in the ſouthern parts of Africa are the haunts of this beautiful animal. They are of a ſocial diſpoſition, and in a ſtate of wildneſs, herd in troops of a hundred or more together; and it is obſerved that though they inhabit the ſame deſerts as the zebra they never aſſociate with that ſpecies. The quagga, unlike the zebra, is of a tractable nature: in ſize it is ſmaller, but ſtronger, and in proportion more robuſt. The attempts of the coloniſts of the Cape to reduce this animal to a ſtate of ſervitude, like the horſe, has been attended with ſome ſucceſs; an inſtance of this is mentioned by Sparrmann. Quagga, opeagha, and alſo *ewah*, or *kwah*, are the names by which the Hottentots diſtinguiſh this animal; its cry reſembles the barking of a dog, in which ſounds, ſimilar to the latter words, are frequently repeated. Its fleſh, which reſembles that of the zebra, is eaten by the natives.

Appendix.

Biſulcus. Hoofs cloven. Gmel. *Guémul*, or *Huémul*, Molina. Hiſt. Chili.

The cloven-footed, or Chileſe horſe, is an animal of very ambiguous character, and which, if our ſuſpicions be well founded, will be removed from the equus tribe whenever naturaliſts become better acquainted with this ſuppoſed ſpecies than they appear to be at preſent. The animal ſeems to have been unknown till obſerved by Wallis in the ſtraits of Magellan. Molina, in his "Storia Naturale del Chili," deſcribes it as a horſe, under the title of *Guémul* or *Huémul*, and, as later writers depend on the authority of Molina for their deſcription of this anomalous animal, it may not be amiſs to repeat the particular information his account affords us. The guemul is deſcribed by him as reſembling in different reſpects both the horſe and the aſs; it bears an affinity to both, but cannot appertain to either; the diviſion of the hoofs alone being ſufficient to remove it from theſe apparently congenerous animals. In point of ſtature and appearance, the texture of the hair, and colour, the guemul, according to Molina, reſembles the aſs. The form and diſpoſition of the teeth correſpond with thoſe of the horſe. The ears are not long, as in the aſs; they are ſhort, ſtraight, and pointed, as in the horſe; neither is the back or ſhoulders of the guemul marked with the black ſtripe by which the aſs is uſually diſtinguiſhed. The head is better formed than that of the aſs, the cheſt more elegant, and the tail and buttocks more graceful. The internal conformation affords the moſt obvious diverſity; and the voice, dependant, in a material degree, on this interior organization, rather reſembles the neighing of the horſe than the bray of the aſs. Gmelin is not correct in his tranſlation from Molina, when he deſcribes the "ſtructura interna," &c. as correſponding with that of the aſs; this point may be thought material to the developement of the true character of the animal, and ſhould be therefore mentioned; and the more eſpecially ſince the ſame miſtake prevails in all the Engliſh deſcriptions of this cloven-footed, or Chileſe horſe, that we have ſeen.

Molina ſpeaks of the guemul as an animal of a vicious nature, wild, and of ſurprizing velocity. It inhabits the heights of the moſt inacceſſible mountainous regions of the Andes of Chili; and it is ſaid, beſides, to be found in other Alpine tracts of South America.

The information upon which this animal is deſcribed appears to be not ſufficiently explicit. We think the guemul ought not to be retained with the horſe or equus tribe. Perhaps it is of the camelus tribe, or that, with ſtill more propriety, it ought to be allowed to conſtitute a new genus. An ingenious writer obſerves, that "if only a ſingle ſpecimen of this animal had been deſcribed, we might have heſitated as to admitting it otherwiſe than as an accidental variety." We could have wiſhed the other authorities alluded to had been adduced. The continental naturaliſts offer argument and ſpeculation dependant on the deſcription given by Molina only; any farther information would therefore prove acceptable. In the Gmelinian "Syſtema Naturæ" this animal is claſſed as a horſe. Sonnini conſiders it as allied to the lama, or camelus glama, and camelus vicugna. According to the character "pedes ungula indiviſa," eſtabliſhed by Linnæus for the equus genus, nothing can be more abſurd than a cloven-footed horſe. Its affinity to the camel appears rather more evident, or, as before intimated, if it be not of that tribe, it is not improbable that it may conſtitute a new genus.

Equus *Marinus*, in *Ornithology*, the *Fulmar* of Pennant and Latham, and the Procellaria *Glacialis* of other writers, which ſee.

Equus *Marinus*, in *Zoology*, a name given by ſome to an animal very different from the hippopotamus, or river-horſe, and more uſually known by the name of the *Morſe*. See Trichechus *Roſmarus*.

ERA, in *Chronology*. See Æra.

Era, in *Geography*, a river of Tuſcany, which runs into the Arno; 14 miles above Piſa.

ERABA, a town of Perſia, ſituated on the eaſtern bank of the river that anſwers to the Arabius of Alexander and Nearchus.

ERACLISSA, in *Botany*, ſo named by Forſkall, from the Greek village near which he gathered it, is according to Juſſieu, no other than *Andrachne telephioides* of Linnæus. See Forſk. Fl. Ægyptiaco-Arab. 208.

ERACTUM, in *Ancient Geography*, a town of European Sarmatia, in the country of the Baſtarnæ, according to Ptolemy. It has been thought to be the modern *Row*, a ſmall town of Podolia.

ERADICATIVE, in *Medicine*. See Radical.

ERÆ, in *Ancient Geography*, a ſmall maritime, fortified town of Aſia Minor, in Ionia, according to Strabo, who ſays that it was either founded or poſſeſſed by the Teians.

ERAGE, a town of Africa, in the Pentapolis, according to Ptolemy.

ERAGISA, Rajik, a town of Syria, in the Cyrrhaſtii territory, upon the banks of the Euphrates, according to Ptolemy, ſituated S. S. E. of Hierapolis.

ERAGROSTIS, in *Botany*, from ερος, *love*, and αγρωστις, *graſs*, the name of an elegant graſs, *Poa Eragroſtis* of Linnæus, called in Latin *Gramen Amoris*, and in French *Amourettes*. See Sm. Fl. Græc. Sib. t. 73, where the Linnæan *Briza Eragroſtis* is given as a ſynonym.

ERANA, in *Ancient Geography*, a borough of Aſia, in Cilicia; being the chief place of mount Amanus, upon which it was ſituated, on the ſame ſide with the altars of Alexander. Cicero ſays it reſembled a town rather than a village.

ERANARCHA, formed of ερανος, *alms*, *contribution*, and αρχη, *command*, a public officer among the ancient Greeks, whoſe buſineſs was to preſide over and direct the alms given, and proviſions made for the poor.

The eranarcha was properly the adminiſtrator or ſteward of the poor: when any perſon was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. this officer called an aſſembly of friends and neighbours, and taxed each, according to his means and eſtate, to contribute towards his relief. This is what we learn from Cornelius Nepos, in his life of Epaminondas.

ERANG, in *Geography*, a town of the iſland of Ceram.

ERANGELIA, in *Botany*, (Ηραγγελια, the herald of ſpring), a name given by Renealm in his Specimen Hiſtoriæ Plantarum, 97, to the Snow-drop. See GALANTHUS.

ERANNA, in *Ancient Geography*, a town of the Peloponneſus, in Triphylia, a province of the Elide. Strabo calls it *Erana*, and places it between Cypariſſia and Pylus.

ERANNOBOAS, or ERRANOBOAS, a river of India, according to Arrian; ſituated within the Ganges, into which it diſcharged itſelf near the town of Palibothra. This river was of the third degree of magnitude among the Indian rivers, and inferior to none but the Ganges and Indus. Major Rennell cannot apply the name Erranoboas to any particular river. Pliny certainly ſays, that the Jomanes (Jumnah) entered the Ganges by Palibothra, between Methora and Cliſobara (otherwiſe Caryſobora and Cyriſoborca): but it is equally true, that in another place he mentions the conflux of the Ganges and Jomanes, and in the very next article ſays that Palibothra is ſituated 425 miles below that very point of conflux. Strabo does not give the name of the adjoining river. See PALIBOTHRA.

ERANTHEMUM, in *Botany*, from ερα, *the earth*, and ανθος, *a flower*, according to Linnæus (Phil. Bot. 177.) who is the author of the name; but ſuch a derivation is, in the preſent inſtance, wholly deſtitute of any appropriate meaning. We ſhould have ſuppoſed it rather from ερος, love, on account of the beauty of the flower, which might well juſtify ſuch a denomination; and it is not impoſſible that Linnæus might have had this idea in his mind when he wrote the Flora Zeylanica, but forgot it when compoſing his Philoſophia Botanica. Linn. Fl. Zeyl. 6. Diſſ. Nov. Gen. Pl. 1. Am. Acad. v. 1. 384. Gen. Pl. ed. 4. 418. ed. 6. 11. Schreb. 15. Willd. Sp. Pl. v. 1. 51. Mart. Mill. Dict. v. 2. Juſſ. 110.

Gen. Ch. *Cal.* Perianth five-cleft, tubular, very narrow, erect, ſhort, pointed, permanent. *Cor.* of one petal, funnel-ſhaped; tube very long and thread-ſhaped; limb deeply five-cleft, (occaſionally four-cleft), flat, its ſegments obovate. *Stam.* Filaments two, very ſhort, in the mouth of the corolla; anthers nearly ovate, compreſſed, projecting beyond the tube. *Piſt.* Germen ovate, minute; ſtyle thread-ſhaped, reaching to the top of the ſtamens; ſtigma ſimple. *Peric.* and *ſeeds* not known. Linnæus adds, that he had ſeen only a ſingle ſpecimen, (which by the mark †, was a dried one), and therefore he left the genus to the attentive examination of other botaniſts.

Eſſ. Ch. Corolla five-cleft; tube thread-ſhaped. Anthers projecting beyond the tube. Stigma ſimple. Fruit ....

Such are the characters given by Linnæus, and copied by Schreber, but the plant whence they were taken being no other than a *Juſticia*, very near, if not the ſame with *J. pulchella*, Roxb. Corom. t. 177, *Eranthemum* falls to the ground. Linnæus indeed, in his own Gen. Pl. has made the following manuſcript corrections: that the two upper ſegments of the calyx are the ſhorteſt; ſegments of the corolla not obovate but oblong, two of them joined together; anthers within the mouth of the tube.—Whence theſe corrections were taken we have no knowledge; probably from ſome of the plants he ſubſequently referred to *Eranthemum*, for he certainly never again ſaw the ſpecimen he originally deſcribed from Herman's herbarium, nor had he in his own any thing to illuſtrate the ſubject. In the Species Plantarum one ſpecies only is mentioned, by the name of *E. capenſe*, ſaid to grow in Ethiopia, and to have the habit of a *Chironia*; yet he comprehends under it the plant of his Flora Zeylanica, which, as we have ſaid, is a *Juſticia*, and with this laſt the ſynonyms of Herman's Paradiſus, Amman and Ray have certainly no connection. In the thirteenth and fourteenth editions of the Syſtema Vegetabilium *Selago dubia* of Sp. Pl. having but two ſtamens and its fruit not aſcertained, is called *Eranthemum anguſtifolium*; while another ſpecies, called *parvifolium*, is adopted from Bergius, along with a ſynonym of Commelin, who figures it with four ſtamens and all the aſpect of a *Selago*; indeed Linnæus, in his own copy of Bergius, has expreſſed a ſuſpicion of its being ſuch. *E. ſalſoloides*, from Teneriffe, the only ſuppoſed ſpecies beſides is deſcribed in the Suppl. Pl. but wholly unknown to us. How far the above, and other ſpiked ſpecies of *Selago*, may conſtitute a genus by themſelves, as Juſſieu ſuſpects, we muſt leave in doubt; but if ſo, they cannot have any thing to do with the name or the above generic characters of *Eranthemum*. S.

ERANUSA, in *Ancient Geography*, a ſmall town of Italy, placed by Pliny near the promontory of Lavinium.

ERARIUM. See ÆRARIUM.

ERAS, in *Ancient Geography*, a town of Aſia Minor, in Ionia, in the vicinity of Epheſus, according to Thucydides.

ERASED, in *Heraldry*, expreſſes any thing that ſeems violently torn off from its proper place. It is uſed in contradiſtinction to couped, which ſignifies a thing clean cut off. The family of Card bears ermine, a demy lion rampant eraſed, azure, &c.

ERASINUS, in *Ancient Geography*, a river of the Peloponneſus, in Arcadia, according to Strabo, who ſays that this river had its mouth near Bura, in the gulf of Corinth.—Alſo, a river of Greece, in Eretria. Strabo.—Alſo, a river of Greece, in Attica, near Brauron. Strabo.—Alſo, a river of Aſia Minor, in Lycia.—Alſo, a river of the Argolide, towards the S. E. of Cenchrea, which formed a confluence with the Phryxus.

ERASISTRATUS, in *Biography*, a phyſician of great reputation among the ancients, but of whoſe parentage and birthplace, as well as of the æra in which he flouriſhed, different accounts have been tranſmitted to us by different writers. It appears moſt probable, however, that he was born at Julis, in the iſle of Cea or Ceos, (and not in Cos, the birthplace of Hippocrates, as has been aſſerted,) that he was the moſt diſtinguiſhed pupil of Chryſippus, the Cnidian phyſician, and had attained a high character in his profeſſion in the 123d olympiad. His fame acquired him the notice and eſteem of Seleucus Nicanor, king of Syria, at whoſe court he is ſaid to have evinced his ſagacity in the following manner. Antiochus, the king's ſon, was ſeized with a ſevere malady, and the moſt ingenious phyſicians of the time were unable to diſcover the cauſe of it; until Eraſiſtratus, obſerving the prince moſt attentively, remarked, that whenever Stratonice, his father's ſecond wife, entered his apartment, he became conſiderably agitated, a bluſh ſuffuſed his countenance, his voice grew more feeble, and his pulſe quickened:—whence the phyſician decided that his diſorder was the effect of a concealed paſſion for Stratonice. In order to inform the king of this delicate affair, he ſtated that

Antiochus's diſeaſe was the reſult of a paſſion, the more unfortunate as it could not be gratified. The king, ſurpriſed at the impracticability of gratifying the inclinations of his ſon, demanded eagerly who was the object of his love. "My wife," replied Eraſiſtratus, promptly. Seleucus having urged him ſtrongly not to occaſion the death of his ſon, by refuſing to give up his wife, Eraſiſtratus inquired, if he would give up Stratonice to ſave his ſon's life, were ſhe the object of his affection; with which the king expreſſed his ready compliance, and Eraſiſtratus avowed that this would be the only means of preſerving the life of Antiochus. Seleucus immediately declared him king of the provinces in Upper Aſia, and gave him Stratonice in marriage, although ſhe had already had one child.

The great character of Eraſiſtratus, however, is founded upon more ſolid ground than this anecdote diſplays. He may be conſidered as the father of anatomical ſcience, at leaſt conjointly with Herophilus. It ſeems to be clearly eſtabliſhed, that, before the time of theſe phyſicians, no one had dared to diſſect human bodies; anatomical examinations had been confined excluſively to the bodies of brutes. Human bodies had, indeed, been opened for the purpoſe of embalming, among the Egyptians, but no anatomical inquiry had reſulted from that practice. The Ptolemies, eſpecially Soter and Philadelphus, being deſirous that the arts ſhould be cultivated, and having ſurmounted the prejudices of the age, granted the bodies of malefactors to the phyſicians for diſſection, of which opportunity Eraſiſtratus and Herophilus availed themſelves largely, and made ſeveral important diſcoveries. To what extent theſe diſcoveries were carried, it is not eaſy to aſcertain, ſince the works of theſe phyſicians are loſt; and what we learn reſpecting them is chiefly through the medium of Galen, who deeming Eraſiſtratus in ſome ſort a rival of his idol, Hippocrates, ſeldom quotes him but to confute him. It is aſſerted by Celſus (De Medicinâ, Præfat.), that the monarchs above-mentioned took the condemned criminals from priſon, and gave them up to Eraſiſtratus and Herophilus, who diſſected them alive, in order to obtain a more accurate knowledge of the vital motions. (See EMPIRIC.) It has been doubted, however, whether they were guilty of this barbarous practice, in conſequence of their adoption of the opinion of Praxagoras, that the veins only received blood, and the arteries, and left ventricle, air; ſince, if they had opened the living body, they muſt have had ocular demonſtration of the exiſtence of blood in the latter: and this imputation is ſuppoſed to have been thrown upon them in a fabulous age; juſt as Medea is ſaid to have boiled living men, becauſe ſhe was the firſt who practiſed warm bathing. (See Eloy Dict. Hiſt.) It would appear, however, from the ſtatement of Galen, that the evidence of their ſenſes, upon this ſubject, was contravened by this ſort of ſubterfuge: "as ſoon as the left ventricle of the heart is opened," they obſerved, "the air is diſſipated, and the ventricle is inſtantaneouſly filled with blood." (Galen, an ſanguis ſit naturâ in arteriis.)

Eraſiſtratus and Herophilus were the firſt who diſſected the human brain accurately; according to the fragments preſerved by Galen, Eraſiſtratus deſcribed the brain minutely, its convolutions, the diviſion of cerebrum and cerebellum, its cavities or ventricles, with their paſſages of communication, and the origin of the nerves; and he inferred that the brain was the common ſenſorium, or ſource of all the vital actions and ſenſations, which were effected through the medium of the nerves. (Galen, De Hippoc. et Platon. decret. lib. vii. cap. 3.) He alſo examined minutely the ſtructure of the heart and of the great veſſels, and was the firſt to point out the valvular apparatus, and its peculiar form in each of the cavities of that viſcus. (Loc. cit lib. i. cap. 10. and lib. vi. cap. 6.) He affirmed that the veins divided in the liver, for the purpoſe of ſecreting the bile; and knew that the urine was ſecreted by the kidnies.

His phyſiology, in general, was not, however, very profound, and his pathology neceſſarily imperfect; although he attempted to explain the cauſes of diſeaſes from his knowledge of the ſtructure of the body. The function of reſpiration ſerved, in his opinion, merely to fill the arteries with air. "The thorax being dilated," he ſaid, "the lungs expand at the ſame time, and receive air: this air paſſed to the extremities of the diviſions of the trachea, and from them into the extremities of the pulmonary artery, whence it is pumped into the heart, by the dilatation of that organ, in order to be diſtributed to all parts of the body, by the great artery." He attributed digeſtion to attrition produced by the coats of the ſtomach; but he did not attempt to explain the particular manner in which the ſtomach accompliſhed ſuch attrition.

The hypotheſis, by which Eraſiſtratus attempted to explain the origin of inflammation, reſembled, in its leading feature, that modern ſuppoſition, which, ſanctioned by the name of Boerhaave, was generally received in the medical world for a long ſeries of years. (See ERROR *loci*.) He maintained, as we have already ſtated, that the great vein (*vena cava*) was the reſervoir of blood, and the great artery (*aorta*) the reſervoir of air. "Theſe reſervoirs are divided and ſubdivided," he affirmed, "until they arrive at the ſurface, where the ramifications become ſo minute, that the blood cannot paſs farther. Here the mouths or extremities of the arteries and veins cloſe to each other, but the blood continues within its proper bounds, and does not enter the arterial or air-veſſels, ſo that the body continues in the natural ſtate. But when any cauſe of violence occurs to diſturb this regularity, the blood is inſinuated into the arteries, and hence the origin of diſeaſes. Among the cauſes of diſturbance juſt alluded to, too great abundance of blood is the principal; for by it the coats of the veins are preternaturally dilated, and their extremities, which are ordinarily impervious, open, and admit of the paſſage of the blood into the arteries. This transfuſed blood becomes an impediment to the courſe and motion of the arterial ſpirit or air, which is ſent from the heart; and if the oppoſition of the two matters is direct, or if the blood be arreſted near a vital part, a *fever* is produced; but if the air repel the blood, ſo that it paſs not farther than the extremity of the artery, *inflammation* of that part is the conſequence." (Galen, de venâ ſect. adverſ. Eraſiſtratum.)

The practice of Eraſiſtratus, like that of his maſter Chryſippus, was extremely ſimple. He did not employ bloodletting, nor purgatives; conſidering the former as hazardous in the operation, and debilitating in its effects, and the latter as not bringing away the proper humours of the body, but humours in a ſort of corrupted ſtate. He ſometimes employed glyſters, but theſe of the mildeſt qualities. All theſe remedies operated, in his opinion, by reducing plethora, which might be effected more ſafely and naturally by faſting, or abſtinence in diet, eſpecially when aided by exerciſe. He adviſed his patients, therefore, to uſe ſuch articles of diet as contained little nutriment, as melons, cucumbers, and vegetables in general. He was exceedingly averſe from the employment of compound medicines, and eſpecially of the mixture of mineral, vegetable, and animal ſubſtances; and he exclaimed againſt the uſe of the antidotes of the phyſicians of his day, in which ſimplicity was altogether ſhunned.

From the fragments of his writings to be found in Galen and Cælius Aurelianus, it would appear, that Eraſiſtratus wrote an accurate treatiſe on the dropſy, in which he diſapproves of the operation of tapping; and that he had left other books on the following ſubjects:—*viz.* on the Diſeaſes of the Abdomen, on the Preſervation of Health, on wholeſome Things, on Fevers, and Wounds, on Habit, on Palſy, and on Gout.

Having lived to extreme old age, and ſuffering ſeverely from the pains of an ulcer in the foot, Eraſiſtratus is ſaid to have terminated his exiſtence by ſwallowing the juice of cicuta, or hemlock. See Le Clerc, Hiſt. de la Medicine, Eloy, Dict. Hiſt. Cælius Aurel.

ERASMUS, Desiderius, a man of great celebrity in the republic of letters, was born at Rotterdam on the 28th of October, 1467. He was the natural ſon of Gerard, a native of Tergou, by Margaret the daughter of a phyſician, whom he intended to marry, but being deceived by a report of her death, he entered into the church, and on this account Eraſmus has been called, by way of reproach, the ſon of a prieſt, though his father was not in orders at the time of his birth. When Eraſmus was about nine years old he was ſent to ſchool at Deventer, where he made very conſiderable progreſs in learning, and was particularly diſtinguiſhed by the excellence of his memory. His mother, who followed him to Deventer, to watch over his health, died of the plague when he was about 13 years of age. He was now left an orphan, and his guardians, forgetful of the ſacred truſt repoſed in them, forced him into the church with a view of embezzling his property. Eraſmus reſiſted their importunity for a conſiderable time, but at length, when he was nineteen years old, he entered among the regular canons in the monaſtery of Stein, near Tergou. He was of a delicate conſtitution, and his health was not ſufficiently robuſt for the life of a monk. His temper and ſentiments were likewiſe averſe from the habits of the profeſſion; he accordingly, with the leave of his ſuperiors, accepted, in his 23d year, an invitation to reſide with the archbiſhop of Cambray; but finding the patronage of that prelate not equal to his expectations, he went to Paris and ſtudied in the college of Montaigne. Here he ſupported himſelf by giving private lectures to thoſe who were leſs advanced in their learning than himſelf. His neceſſities required great exertion, and thus he acquired habits of induſtry which raiſed him to the higheſt pitch of literary excellence. Some of his pupils at Paris were the ſons of Engliſhmen of conſiderable conſequence, by whoſe liberality and earneſt requeſt he viſited their country, and contracted many valuable friendſhips. This was in the year 1497; from England he went to Italy, continued a year or more at Bologna, from thence to Venice, where he publiſhed his Adagia; afterwards to Padua, and at laſt he viſited the capital, Rome, where his reputation was very high, and where he might have ſettled to great advantage, had he not determined, at the entreaties of his friends, and by the expreſs invitation of Henry VIII. to return to England. Henry, while prince, had contracted a friendſhip and high reſpect for Eraſmus, and in a few months after he ſucceeded to the crown, we find Eraſmus at the court of London high in favour with the monarch, with Wolſey, with the archbiſhop of Canterbury, and with other perſons of diſtinction.

At firſt he lived with ſir Thomas More, under whoſe roof he wrote his "Moriæ Encomium," or "Praiſe of Folly," a witty and ſatirical compoſition. He afterwards went to Cambridge, and read lectures to the ſtudents in Greek and theology. For this he was remunerated with a living and many valuable preſents, though not of ſo ſubſtantial a nature as to ſatisfy his expectations. He wiſhed for an independency, and not being able to ſecure that in England, he went over to Flanders in 1514, and was ſhortly after created nominal counſellor to prince Charles of Auſtria, with a ſtipend. Soon after this he paid a viſit to Baſil, where he formed an intimacy with ſome valuable friends, which induced him to ſpend his latter days in that place. At Baſil he publiſhed, in the year 1516, his New Teſtament, in Greek and Latin, which was received with the utmoſt eagerneſs by all thoſe whoſe minds were turned to theological purſuits. It was dedicated to Leo X. In the courſe of the ſame year, his edition of St. Jerome, a favourite author, made its appearance, which he inſcribed to his generous patron, archbiſhop Warham. Eraſmus was ever inimical to that ſyſtem of war which in his time, as in ours, was but too much in faſhion among the ambitious rulers of mankind; he publiſhed, in 1517, a work entitled "Querela Pacis, undique gentium ejectæ profligatæque," which is written with much ſtrength of reaſoning and true eloquence. By his contemporaries he was charged with maintaining the unlawfulneſs of war on all and every occaſion: this, however, was a calumny invented by his enemies, of whom he had many, for, in the work alluded to, he expreſsly ſays he is ſpeaking only of wars undertaken on trifling and unjuſtifiable occaſions. "I think," ſays he, "very differently of wars, which are ſtrictly and purely defenſive, ſuch as with an honeſt and affectionate zeal for the country, repel the violence of invaders, and at the hazard of life, preſerve the public tranquillity." He was aware of the horrors and atrocities of a ſtate of warfare, and thought almoſt any ſacrifice might be made by wiſe princes to prevent it. He undertook to vindicate the cauſe of peace, whom he makes the ſpeaker on this occaſion. But the arguments which he puts into her mouth, and the perſuaſive eloquence with which ſhe addreſſes the ſovereign princes of thoſe dark times, as they are ſometimes called, would ſcarcely be borne by the monarchs of Europe in this enlightened age. His deſcriptions are vivid, and his reflections but too juſt: "Exuruntur vici, vaſtantur agri, diripiuntur templa, trucidantur immeriti cives, dum princeps interim otioſus ludit aleam, dum ſaltitat, dum delectat ſe morionibus, dum venatur, dum amat, dum potat. O Brutorum genus jam olim extinctum! O fulmen Jovis aut cæcum aut obtuſum." To whom this is particularly applied it does not appear, but the "Querela Pacis" was occaſioned by the following remarkable circumſtance:

It was a favourite project at this period to aſſemble a congreſs of kings at Cambray, conſiſting of the emperor of Germany, the kings of France, England, and the Low Countries; "of which," ſays the author, "I am a native. They were to enter into mutual and indiſſoluble engagements to preſerve peace with each other, and throughout Europe. This momentous buſineſs was very much promoted by William a Ciervia, and by one, who ſeemed to have been born to advance the happineſs of his country, and of human nature, John Sylvagius, chancellor of Burgundy. But certain perſons, who get nothing by peace, and a great deal by war, threw obſtacles in the way which prevented this truly kingly purpoſe from being carried into execution. After this great diſappointment, I ſat down and wrote, by deſire of Sylvagius, my Querela Pacis." This work was dedicated to Philip of Burgundy, biſhop of Utrecht, who was likewiſe a zealous promoter of peace, and who, ſo far from being offended with the free ſentiments of the book, thanked the author, and even preſſed him to accept a living, as a remuneration, which he civilly refuſed. Eraſmus ſought no preferment, though, ſays his biographer, he merited the higheſt: he ſought the happineſs of his fellow creatures, and felt himſelf abundantly rewarded by his own conſcience, and their approbation. The biſhop, however, in token of his high eſteem, ſent him a moſt beautiful ring, ſet with a ſapphire, which his own brother, his predeceſſor, in the biſhopric, had conſtantly worn, and which he deſired Eraſmus to wear for his ſake.

The commencement of the reformation, under Luther, was a circumſtance of conſiderable importance in the life of Eraſmus. He had ſhewn himſelf inimical to the ſuperſtitions of the times, he had arraigned the principles and practices of the monks, and had done much to undermine the whole ſyſtem of popery, and to expoſe the various frauds which had been attached to its obſervance by avaricious and licentious prieſts; yet he was not prepared to join the reformers as ſuch, his zeal was not ſufficient to enable him to endure perſecution: he did not wiſh to break openly from the church, nor was he quite ſatisfied with the doctrines of the reformers, and ſtill leſs was he diſpoſed to coaleſce with the rudeneſs, vulgarity, and contempt of polite literature which characterized ſome of that claſs of people. It has alſo been ſaid that he was very deſirous of being noticed by the great, that he had habituated himſelf to that degree of indulgence, which would render the proſpect of poverty and impriſonment abſolutely inſupportable to his mind. His income likewiſe aroſe almoſt entirely from penſions which he received from crowned heads, prelates, and men of conſequence belonging to the Catholic perſuaſion, which he would unqueſtionably have loſt had he gone over to the oppoſite ſide. Theſe are the reaſons which have been aſſigned why Eraſmus did not come boldly forward in defence of the reformation; but with theſe deductions there is enough in his character to challenge the admiration and gratitude of the friends to liberty and the human race. He was ever the undaunted advocate of free enquiry, and perpetually waged war againſt the ignorance and bigotry that characterized the age in which he lived. On theſe accounts he was, in the firſt years of the reformation, highly regarded by Luther, and it was owing to ſome unadviſed, and, probably, unwarranted attacks made upon Eraſmus, about the year 1520, by the zealous reformers, that he was driven to enliſt among the defenders of the church of Rome.

In the year 1522, he publiſhed his "Colloquies," which, though apparently intended for young perſons, were generally read, and are ſuppoſed to have been very efficacious in promoting the principles of the reformation. As ſoon as their tendency was diſcovered, the clergy attempted to ſtop their ſale, but it was then too late; more than twenty thouſand copies of them were diſpoſed of in Paris, beſides a number of editions which were printed and ſold in other places.

In 1524, Eraſmus publiſhed his treatiſe, "De Libero Arbitrio," which was an avowed attack upon Luther's opinion concerning predeſtination, but the author, in his zeal, ſpoke againſt reformers in general; Luther replied, and had unqueſtionably the beſt of the argument: in ſome paſſages he ſeemed to commiſerate the caſe of his antagoniſt, and to regret the neceſſity that he was under of expoſing him. "We ſaw," ſays he, "that the Lord had not conferred upon you the diſcernment, the courage, and the reſolution to join us in oppoſing thoſe monſters, and therefore we dared not to exact from you that which greatly ſurpaſſes your ſtrength and capacity." He then refers to the motives of worldly intereſt by which Eraſmus had ſuffered himſelf to be ſwayed from the path of rectitude. The controverſy increaſed in violence, and much unjuſtifiable acrimony proceeded from the pens of the diſputants. Under the article Reformation we ſhall have occaſion to enter more at large into this ſubject, and alſo into the controverſy between Eraſmus and Melancthon.

Another antagoniſt with whom our author had to contend was Julius Cæſar Scaliger, who had put himſelf at the head of thoſe who were ſo faſtidious in the uſe of pure Latin as to reject every word not to be found in the works of Cicero, and who on that account had aſſumed the title of "Ciceronians." Eraſmus, ſuperior to this pedantry, employed new words for new ideas, and in juſtification of his conduct publiſhed, in 1528, a dialogue entitled "Ciceronianus," in which he attacked the ſect both with argument and ridicule. Scaliger wrote againſt him with all the malignity that human wit and learning could deviſe, and he was backed in his ſcurrility by others of the Ciceronians leſs able in the warfare, but not leſs inveterate than their maſter. The nature of this controverſy is fairly exhibited in the notes on the life of Eraſmus by Bayle.

Eraſmus, wearied, perhaps, by diſputation, publiſhed, in a ſhort time after his "Ciceronianus" had made its appearance, a treatiſe of much ability and learning, entitled "De Recta Latini Græcique ſermonis Pronunciatione." In the year 1529, Eraſmus left Baſil for Friburg, in order to ſhew his attachment to the church which had for ſome years been loſing ground in Baſil, and ſo completely had the reformed religion gained an aſcendancy there at this period, that all the images were taken from the town-houſe and other public places and burnt, which was ſuppoſed to have been the means of putting an end to the differences among the common people. Eraſmus was now advancing in life, and ſeemed, more than ever, fearful of being thought friendly to the reformation, and to ſhew his zeal for the oppoſite ſyſtem he wrote and publiſhed an epiſtle againſt ſome "who falſely call themſelves Evangeliſts," and as they, from his former works, had produced his authority againſt perſecution, he began to maintain that there were certain caſes in which they might lawfully be puniſhed capitally as blaſphemers and ſeditious perſons. Such were the unworthy ſteps to which he was led by an anxiety to keep on good terms with his patrons and protectors.

In 1535 he returned to Baſil, and ſo highly was he eſteemed by the church of Rome, that there was an intention to give him a place in the college of cardinals; but it was too late for him to accept of the high honour. His health rapidly declined, and on July 12, 1536, he died of a dyſentery at the age of ſixty-nine. He was buried with great funeral pomp in the cathedral church of Baſil, where his tomb ſtill remains. By his will he left legacies to ſeveral friends, and the reſidue of his property he devoted to charitable purpoſes. In perſon he was below the middle ſize, well-ſhaped, of a fair complexion, with a chearful countenance, a low voice, and agreeable elocution. He had aſſumed the name of Eraſmus in conformity with the pedantic taſte then prevailing among men of letters of taking names of Greek or Latin etymology; he tranſlated his name of "Gerard," ſignifying "Amiable," into the equivalent ones of "Deſiderius" in Latin, and "Eraſmus" in Greek, making uſe of both, but the latter was his common and perpetual appellation.

Eraſmus was a voluminous writer; and his works were publiſhed in nine volumes folio. They conſiſt of numerous tranſlations from the Greek; of grammatical and philological pieces; of poems, declamations, and orations; of a collection of adages and apophthegms; of works in divinity on various topics, moral, didactic, and controverſial; of a verſion of the New Teſtament, paraphraſes of the goſpels and the epiſtles, and commentaries on ſome other parts of ſcripture; and of apologies, epiſtles to correſpondents, &c. A new and handſome edition of his works was publiſhed in Holland by Le Clerc in eleven volumes folio,

1703. Dr. Jortin, the biographer of Eraſmus, ſpeaking of his Latin ſtyle, ſays, it "is that of a man who had a ſtrong memory, a natural eloquence, a lively fancy, and a ready invention, who compoſed with great facility and rapidity, and who did not care for the trouble of reviſing and correcting; who had ſpent all his days in reading, writing, and talking Latin; for he ſeems to have had no turn for modern languages, and perhaps he had almoſt forgotten his mother-tongue. His ſtyle, therefore, is always unaffected, eaſy, copious, fluent, and clear; but not always perfectly pure and ſtrictly claſſical."

No one contributed ſo much as Eraſmus to throw diſcredit upon the barbariſm and ignorance of the ſchools, or to make literature agreeable, and connect it with good ſenſe and ſolid criticiſm. He was a great public benefactor; and therefore he is juſtly regarded as one of the principal glories of his age and country. His memory is equally honoured at the place of his birth and of his death. Several of his relics are preſerved at the latter place, and at the former, the houſe in which he was born, is marked with an inſcription, and his ſtatue decorates the great ſquare. Jortin's life of Eraſmus. Bayle. Complaint of Peace. 1802.

Eʀᴀsᴍᴜs, in *Geography*, a mountain of the iſland of Ceylon; 30 miles N.W. of Trincomaly.

ERASTIANS, in *Eccleſiaſtical Hiſtory*, a religious ſect or faction, which aroſe in England during the time of the civil wars, thus called from their leader, Thomas Eraſtus, a German divine of the ſixteenth century, whoſe diſtinguiſhing doctrine was, that the church had no right to diſcipline, that is, no regular power to excommunicate, exclude, cenſure, abſolve, decree, or the like.

According to the founder of this ſect, the paſtoral office was only perſuaſive, like a profeſſor of the ſciences over his ſtudents, without any power of the keys annexed. The Lord's ſupper and other ordinances of the goſpel were to be free and open to all. The miniſter might diſſuade the vicious and unqualified from the communion, but might not refuſe it, or inflict any kind of cenſure; the puniſhment of all offences, either of a civil or religious nature, being reſerved to the magiſtrate. The pretended advantage of this ſcheme was, that it avoided erecting *imperium in imperio*, or two different powers in the ſame civil government; it effectually deſtroyed all that ſpiritual juriſdiction and coercive power over the conſciences of men, which had been challenged by popes, prelates, preſbyteries, &c. and made the government of the church "a creature of the ſtate." Moſt of our firſt reformers adopted theſe ſentiments ſo far as to maintain, that no one form of church government is preſcribed in ſcripture as a rule for future ages, as Cranmer, Redmayn, Cox, &c. and archbiſhop Whitgift, in his controverſy with Cartwright, delivers the ſame opinion. The Eraſtians formed a party in the Aſſembly of Divines in 1643, and the chief leaders of it were Dr. Lightfoot, Mr. Colman, Mr. Selden, and Mr. Whitlock; and in the houſe of commons there were, beſides Selden and Whitlock, Oliver St. John, eſq., ſir Thomas Widdrington, John Crew, eſq., ſir John Hipſley, and others of diſtinguiſhed reputation. In the aſſembly, the Eraſtians did not except againſt the preſbyterian government as a "political inſtitution," proper to be eſtabliſhed by the civil magiſtrate, but they were againſt the claim of a "divine right." Accordingly the clauſe of divine right was loſt in the houſe of commons. Neale's Hiſt. Purit. vol. ii. 4to.

ERASTUS, Tʜᴏᴍᴀs, in *Biography*, a phyſician, was born, in 1523, at Auggenen, a village in the diſtrict of Badenweiller, in Switzerland. He ſtudied at Baſil, where he was ſeized with the plague in 1542, and narrowly eſcaped death. He ſuffered a long and tedious convaleſcence, which, together with his poverty, threw an almoſt inſurmountable impediment in the way of his ſtudies; but he fortunately found a generous protector, who opened the door of the ſciences to him, and furniſhed him with the means of travelling to Italy. He took up his reſidence at Bologna, where his proficiency in the ſtudy of philoſophy and medicine was ſuch, that he obtained the honour of the degree of doctor of theſe two ſciences. Finding himſelf in a ſhort time holding a diſtinguiſhed ſituation among the men of learning, he followed the cuſtom of the times by changing his name; giving a Greek turn to his original name, which was Lieber, (beloved,) he called himſelf Eraſtus. Under this appellation he became a teacher of medicine at Heidelberg, where he obtained conſiderable reputation; and in 1581 he was called to fill the medical chair in the univerſity of Baſil. But this honourable ſituation he did not long enjoy; he died on the 1ſt of January, 1583.

He left many works behind him, of which ſome were printed during his life, and others have been publiſhed ſince his death; their contents, however, are not particularly intereſting; the following is a liſt of their titles and editions. "Diſputationum de Medicina nova Phillippi Paracelſi," p. i. Baſil, 1572, p. ii. ibid. 1572, p. iii. ibid. 1572, p. iv. et ultima, ibid. 1573, all in 4to. In theſe volumes he refutes the doctrines which Paracelſus had previouſly taught at Baſil, and had committed to writing. 2. "De Cauſa Morbor. Continente," 4to. 1572. 3. "De Occult. Pharmacor. Poteſtatibus," 4to; ibid. 1574; Francofurti, 1611. 4. "Diſputat. de Auro Potabili." 4to. Baſil, 1578, 1594. 5. "De Putredine Liber," 4to. ibid. 1580; Lipſiæ, 1590. 6. "Epiſtola de Aſtrologia Divinatrice," 4to. Baſil, 1580. 7. "De Pinguedinis in Animalibus Generatione et Concretione," 4to. Heidelbergæ, 1580. 8. "Comitis Montani, Vicentini, novi Medicorum cenſoris, quinque Librorum de Morbis nuper Editorum Viva Anatome," 4to. Baſil, 1581. 9. "Ad Archangeli Mercenarii Diſputationem de Putredine reſponſio," 4to. ibid. 1582. 10. "Varia Opuſcula Medica," folio, Franc. 1590. See Eloy Dict. Med. Biog. Dict.

ERATO, from εραω, *I love*, in *Mythology*, the name of one of the nine Muſes who preſided over love-poetry. "By Erato," ſays Callimachus in his epigram on the nine Muſes, "the pious hymn was made." To this Muſe ſome have aſcribed the invention of the lyre and lute; but particularly the pſaltery or long lyre of nine ſtrings; and ſhe is repreſented with a garland of myrtles and roſes, holding a lyre in one hand, and a bow in the other, and at her ſide a Cupid with his torch. In the portraits of Apollo and the Muſes, dug out of Herculaneum, Erato is exhibited holding a plectrum or bow in her right hand, and ſeeming to play with the fingers of her left. The pſaltery, or lyre, is more than twice the length of that in the hand of Terpſichore. (See Mᴜsᴇs.) There is alſo a Nereid of the ſame name.

ERATONOS, in *Ancient Geography*, iſlands of the Arabic gulf. Pliny deſignates their aridity by the epithet *Sitientes*.

ERATOSTHENES, in *Biography*, an eminent Greek mathematician, philoſopher, and chronologiſt, was born at Cyrene in the ſecond year of the 126th olympiad, or 275 B. C. He was educated under Ariſto, the philoſopher of Chios, and Callimachus, the poet; and he himſelf had ſeveral diſciples who were eminent, and among the number was Ariſtophanes of Byzantium, one of the moſt celebrated grammarians of his time. Such was the fame of Eratoſthenes as a man of extenſive erudition, that he was denominated πενταθλος, *i. e.* victorious in five conteſts, alluding to the five prizes of the Olympic games, and expreſſing his pre-eminence in all kinds of literary purſuits. He was alſo ſtyled the coſmographer and father of chronology, the meaſurer of the univerſe, and the ſecond Plato. On the invitation of Ptolemy Euergetes, he removed from Athens to Egypt, and ſucceeded Zenodotus in the office of librarian to the famous library at Alexandria. This office he retained under three ſucceſſive princes, diſcharging his truſt with ſingular honour, and acquiring high reputation for literature and ſcience by his writings and diſcoveries. Availing himſelf of the multitude of hiſtorical memoirs, which the library furniſhed, he was both prompted and enabled to determine the dates of many diſtinct facts, by laying down certain chronological canons, for which ſee CHRONOLOGY. He alſo employed his eminent abilities and learning, with equal ſucceſs, in reducing geography to a regular ſyſtem, and laying its foundation upon clear and ſolid principles. He likewiſe firſt introduced into his map a regular parallel of latitude, which was a geographical outline traced over certain places, whoſe longeſt day was obſerved to be exactly of the ſame length. He began it from the ſtraits of Gibraltar, and it thence paſſed through the Sicilian ſea, and near the ſouthern extremities of Peloponneſus, and was continued through the iſland of Rhodes and the bay of Iſſus, and then entering Cilicia, and ſo croſſing the Euphrates and Tigris, was extended to the mountains of India. By means of this line he endeavoured to rectify the errors in the ancient geographical map, ſuppoſed to be that of Anaximander. In drawing this parallel, he was regulated by obſerving when the longeſt day conſiſted of 14½ hours, which Hipparchus afterwards determined to be the latitude of 36°. The running of this parallel through Rhodes was a happy thought of Eratoſthenes, becauſe it not only encouraged him to trace upon his map other parallels at certain intervals from his firſt, ſuch as one through Alexandria, another through Syene, and another through Meroe, but he undertook to trace at right angles to theſe a meridian paſſing through Rhodes and Alexandria down to Syene and Meroe. His progreſſion this way enlarged his ideas with regard to the ſciences of geography and aſtronomy, and induced him to attempt a more arduous taſk, which was that of determining the circumference of the globe by an actual meaſurement of one of its great circles, making his computation upon the whole by uniting certain accurate obſervations made in the heavens with a correſponding diſtance carefully ſurveyed, and taken upon a meridian of the earth. The ſegment of the meridian which he fixed upon for this purpoſe, was that between Alexandria and Syene, the diſtance of which was meaſured, and found to be 5000 ſtadia, and the angle of the ſhadow upon the ſcaphia, or ſun-dial, which was obſerved at Alexandria, was equal to the 50th part of the circle; for at Syene there was no ſhadow from the gnomon at the mid-day of the ſummer-ſolſtice; and that this might be more accurately taken, they dug a deep well, which being perpendicular, was completely illuminated at the bottom, when the ſun was vertical. The ſubſtance of this account was taken from Cleomedes, who ſeems to have extracted it from Eratoſthenes's original work, entitled Μετρήσεις. (See Fabr. Bell. Græc. vol. ii. p. 477.) And it is publiſhed as ſuch at the end of the Oxford edition of Aratus in 1672, though under the title of Μέτρον τῆς γῆς περιφερείας. By this account Eratoſthenes made the circumference of the earth amount only to 250,000 ſtadia, whereas a multitude of original authors, (ſuch are Strabo, Geminus, Vitruvius, Macrobius, Pliny, Capella, and Cenſorinus,) have uniformly given the numbers to be 252,000. In order to reconcile theſe differences, Dr. Murdoch (Enquiries concerning Meaſures of length, prefixed to Buſching's Geography, vol. i.) has ingeniouſly ſuppoſed, that inſtead of 7° 12′, the difference of latitude was 7° 8½′, which was the $\frac{1}{50\frac{2}{5}}$th of the circumference, which would bring the calculation to 252,000 ſtadia, and that Cleomedes neglected the ſmall fractional part of the denominator; but that the principal miſtake was in meaſuring the diſtance, and finding it to be 5000 ſtadia. Eratoſthenes, by making the circumference to be 250,000 ſtadia, allowed 700 ſtadia to a degree, which, by the reduction of 8 ſtadia to a Roman mile of 5000 feet, amounted to 87½′ Roman miles to each degree. We ſhall return from this digreſſion, after obſerving, that the map of Eratoſthenes appears to have contained little more than the ſtates of Greece, and the dominions of the ſucceſſors of Alexander, digeſted from preceding ſurveys. He had ſeen indeed, and has quoted the voyages of Pytheas into the great Atlantic ocean, which gave him ſome faint idea of the weſtern parts of Europe: but they were ſo imperfect, that they could not be realized into the outline of a chart. Strabo tells us that he was extremely ignorant of Spain, Gaul, Germany, and Britain, as well as of the Gæti and Baſtarni; he was equally ignorant of Italy, the coaſts of the Adriatic, of Pontus, and of all the countries towards the north. And he mentions in another paſſage, that Eratoſthenes had made the diſtance from Epidamnus, or Dyrrhachium, on the Adriatic, to the bay of Thermæ on the Ægean ſea, quite acroſs Epirus, to be only 900 ſtadia, when it was really above 2000 ſtadia; and in another inſtance he had enlarged the diſtance from Carthage to Alexandria to be 15,000 ſtadia, whereas it amounted to no more than 9000 ſtadia.

Eratoſthenes alſo obſerved the obliquity of the ecliptic, which, in the year 230 B. C. he makes 23° 51′ 20″. (See ECLIPTIC.) In an epiſtle to king Ptolemy he gave a ſolution of the problem for the duplication of the cube; and he invented a convenient method of diſcovering the primary numbers, that is, ſuch as have no common meaſure but unity, which has been called the ſieve of Eratoſthenes. He wrote alſo numerous treatiſes in grammar, aſtronomy, hiſtory, and geography, together with dialogues on the philoſophical ſects, and poems. Fragments merely of his different pieces have reached our times, ſome of which were publiſhed at Oxford in 1672, with brief annotations, in 8vo. Theſe fragments were alſo printed in the Uranologium of Petavius at Paris in 1630, and afterwards at Amſterdam in 1703. The moſt valuable remnant of his works is his "Catalogue of the kings of Thebes in Egypt, from Menes, who firſt peopled Egypt after the deluge, to the time of the Trojan war." This contains a ſeries of 38 kings in a direct line of ſucceſſion, taken not only from the records in the Alexandrian library, but from the ſacred archives in Dioſpolis, or Thebes itſelf, and probably intended for ſupplying the defects, and correcting the errors of Manetho's dynaſties. This has been uſed by ſome of our ableſt chronologers as an authority for ſettling the Egyptian chronology. Eratoſthenes died at the advanced age of 80 or 81, having, as ſome authors report, ſtarved himſelf to death, becauſe he was unable to bear the depreſſion of ſpirits occaſioned by the decay of his ſight. Suidas. Voſſ. de Hiſt. Græc. Fab. Bib. Græc. Moreri. Anc. Un. Hiſt. Gen. Biog.

ERBACH, in *Geography*, a ſmall town of Germany, in the circle of Franconia, anciently called Erdtpach, with an old caſtle, belonging to the counts of Erbach, who, before the diſſolution of the German empire, had two voices at the diet of Ratiſbon, in the college of the imperial counts of Franconia. The whole county is about 25 miles in length, and 20 miles in breadth; its population does not exceed the number of 30,000 individuals. It is a mountainous country, but tolerably fertile, and producing both corn and wine; of the latter, that of Schonberg, near the Bergſtraſſe, is reckoned the beſt.

ERBAT, a town of Aſiatic Turkey, in the province of Diarbekir; 58 miles S.E. from Diarbek.

ERBAZ, a town of Aſiatic Turkey, in the province of Natolia; 36 miles W.S.W. from Degnizlu.

ERBITA, in *Ancient Geography*, a town of Sicily, written Herbita by Cicero. It is thought to be the modern *Nicoſia*.

ERBLSPACH, or ERLSBACH, in *Geography*, a town of Germany, in Lower Bavaria; 34 miles E.S.E. from Ingolſtadt.

ERCABUM, in *Ancient Geography*, a town of European Sarmatia. Ptolemy.

ERCE', in *Geography*, a town of France, in the department of the Ille and Vilaine, and diſtrict of Bain; 5 miles E. from Bain.

ERCEUS, of ερκος, *ſeptum*, in *Mythology*, the name by which thoſe who were appointed to guard the walls of a city invoked Jupiter. This appellation, ſometimes written *Herſæus*, was given to Jupiter, becauſe his altars, eſpecially in the houſes of princes, ſtood under the open air in places incloſed with walls.

ERCHEE, in *Geography*, a town of Perſia, in the province of Adirbeitzan; 60 miles E.N.E. of Tauris.

ERCILLA Y ZUNIGA, DON ALONZO DE, in *Biography*, an eminent Spaniſh poet, was born at Madrid in 1533. His father, deſcended from a noble family, purſued the profeſſion of the law, but dying while Alonzo was an infant, the child and his mother were received into the houſehold of Iſabella, wife of Charles V. Alonzo, as ſoon as his years permitted, was made page to the infant don Philip, whom he attended in his progreſs through the Low Countries, and part of Germany and Italy. He afterwards accompanied the ſame prince to England, to celebrate his marriage with queen Mary. During their ſtay here intelligence was received of a revolt in Chili, upon which troops were immediately ſent off, with whom Ercilla embarked and proceeded to Lima. His duty required him perſonally to engage in a ſubſequent war with the Araucanians, whoſe courage and love of liberty he admired, and even applauded, though he was under the neceſſity of uſing all his efforts in ſubduing them. The intervals of warfare he employed in recording, in heroic verſe, the intereſting ſcenes to which he was witneſs. After he had eſcaped the dangers of the expedition, he had nearly loſt his life at a tournament exhibited in honour of the acceſſion of Philip II. During the fête a diſpute aroſe between Ercilla and another gentleman; ſwords were drawn, and many joined in the conflict, which being conſtrued into a plan of mutiny by the governor, he haſtily, and without examining into the matter, condemned the principal diſputants to be beheaded. Ercilla was led to the ſcaffold, and his innocence was demonſtrated but juſt in time to ſave him from an ignominious death. He returned to Spain with his health very much impaired, in his twenty-ninth year; but after a very ſhort ſtay at home, he commenced a tour through various parts of Europe; but with what particular view has never been aſcertained. In 1570 he married, and was made gentleman of the bed-chamber to the emperor Rodolph II. Ten years after this, he was found reſiding at Madrid, in retirement and poverty. The king whom he had ſerved, and to whom he dedicated his poem "Araucana," made him no requital for his ſervices, and little more is known of him, than the mention made by a contemporary of his being engaged, in 1596, in celebrating the victories of the marquis of Santa Cruz, in a poem that has never been publiſhed.

The "Araucana" is an hiſtorical poem, containing a narrative of real events, interſperſed with fabulous circumſtances. It contains 37 cantos, is formed on no regular plan, but is an unconnected ſeries of adventures. The verſe is ſaid to be flowing and ſpirited, though ſometimes it is proſaic and inſipid. Mr. Hayley, in his Eſſay on Epic Poetry, has taken pains to make Ercilla known to the Engliſh reader, by tranſlations of ſelect parts, and an analyſis of the whole poem. Gen. Biog. Hayley on Epic Poetry.

ERCTA, in *Ancient Geography*, a mountain of Sicily, near mount Erix. Diod. Sic. Polybius.

ERCYNA, a river of Greece, in Bœotia, not far from the cave of Trophonius.

ERDENI-TCHAO, in *Geography*, a town of Chineſe Tartary, in the country of the Eluths; 680 miles N.W of Pekin.

ERDER, a town of Germany, in the circle of Weſtphalia, and country of Lippe; 12 miles N.N.E. from Lemgow.

ERDMANSDORF, a town of Germany, in the circle of Upper Saxony, and circle of Erzgeburgh; 5 miles E. of Chemnitz.

EREBENNUS, ερεϐεννὸς, a name given by Galen and ſome other of the Greek writers, as a diſtinctive epithet for the black chamæleon thiſtle, which was eſteemed poiſonous, and was by this word diſtinguiſhed from the ægleus, or ἄιγλὴς, or white chamæleon, which was an eſculent plant, and uſed by ſome as an antidote. It has happened, however, that the white chamæleon thiſtle has been by ſome called a poiſon, as well as the black; but this is only owing to a miſtake of Pliny, in ſuppoſing the effects of birdlime to have been attributed to this plant, becauſe of its yielding a viſcous, but ſafe gum, at its root. It was called by ſome *ixias chamæleon*. See IXIAS.

EREBINTHUS, in *Botany*, (ερεβινθος, an ancient Greek name for ſome kind of vetch or legume), was applied by Mitchel to a ſuppoſed new genus of his own, which is the *Galega virginiana* of Linnæus. The latter in his Sp. Pl. inaccurately quotes Mich. Gen. which ſhould mean Micheli, and profeſſor Martyn, under his *Galega*, ſp. 4, has Mant. Gen. both which would be unintelligible without an explanation

EREBUS, Ερεϐος, from ערב, *night*, in *Mythology*, a term denoting darkneſs. According to Heſiod, Chaos engendered Erebus and Night, from whoſe mixture was born æther and the day. Ariſtophanes, ridiculing ſome ancient ſyſtem of theogony, in his comedy of the Birds, introduces one of his actors as ſaying, that in the beginning were the Chaos, the black Erebus, and the vaſt Tartarus; but as yet there was neither earth, nor air, nor heavens. Night, with her ſable wings, laid the firſt egg in the womb of Erebus, whence ſprung, after ſome time, beneficent love, adorned with golden wings. From the union of love with chaos, aroſe men and animals. This was alſo the name of part of the inferi among the ancients: they had a peculiar expiation for thoſe who were detained in Erebus.

Erebus was properly the gloomy region, and diſtinguiſhed both from Tartarus, the place of torment, and Elyſium, the region of bliſs: according to the account given of it by Virgil, it forms the third grand diviſion of the inviſible world beyond the Styx, and comprehends ſeveral particular diſtricts, as the limbus infantum, or receptacle for infants; the limbus for thoſe who have been put to death without cauſe; that for thoſe who have deſtroyed themſelves; the fields of mourning, full of dark groves and woods, inhabited by thoſe who died for love; and beyond theſe, an open champaign country for departed warriors. *Æn.* lib. vi. p. 427. &c.

EREC, or Erech, in *Ancient Geography*, a town of Chaldæa, which is mentioned in the book of Geneſis (ch. x. v. 10.) as one of the places in which Nimrod began to eſtabliſh his kingdom. This was probably the Aracca, placed by Ptolemy in Suſiana, on the river Tigris, below its confluence with the Euphrates. Ammianus calls it Arecha. From this city the Arectæan fields, which abound with Naphta, and ſometimes take fire, derive their name.

> "Ardet Arectæis aut unda per hoſpita campis."
>
> Tibull.

Erec, a province of Aſia, which extended on both ſides along the common bed of the Tigris and Euphrates, from their junction to the ſea.

ERECT Flowers, in *Botany*, are ſuch as grow upright, without hanging or reclining the head. See Flower.

Erect *leaf*, *erectum folium*. See Leaf.

Erect, in *Fortification*. The defences of a face, in fortification, are ſaid to be erect when the ſeveral works bear directly and regularly upon the approaches, in ſuch manner as to tend uniformly towards the capital, from which they are drawn reſpectively. Thus, when the two baſtions which defend a curtain are equal and ſimilar, and the raveline, with all its dependencies, ſtands evenly upon the line, or capital, of that face, without obliquity, or curve, the whole of ſuch defences are ſaid to be erect. It will be readily underſtood, that in every regular fortification the whole of the defences will be of this deſcription: and that in all irregular fortifications there will probably be a mixture of erect and of oblique defence. The latter is by no means to be conſidered a defect; ſince innumerable caſes might occur in which the prolongation, or the curtailment of any particular part, ſuch, for inſtance, as the face or flank of a baſtion, might be indiſpenſably neceſſary, either to make way for ſome natural advantage, or to prevent that kind of weakneſs which might otherwiſe be entailed by the proximity of ſome height, whence enfilading might be ſucceſsfully practiſed. When, therefore, the two baſtions are diſſimilar, or when they are unequal, ſo as to render the flanked angle of either leſs diſtant on the capital, if a line of defence were to be drawn upon, and formed from, the two extremities of ſuch unequal baſtions, the raveline muſt either ſtand a little obliquely, or the baſtions muſt be unequally protected by it. This kind of obliquity is extremely rare, and is often neglected where great acceſſion of ſtrength might otherwiſe, by its adoption, be given to weak parts: it is peculiarly appropriate to fortreſſes, of which only one or two faces are underſtood to be ſubject to approach.

Erect *Viſion*, in *Optics*. See Vision.

Erect, *direct*, and *declining*, &c. *dials*, &c. See Dial.

ERECTHEUS, in *Biography*, is reckoned the 6th king of Athens, from Cecrops its founder, and is ſuppoſed to have ſucceeded his father Pandion about the year 1397 B. C. Some have referred to this reign the arrival of Ceres in Attica, after the rape of her daughter Proſerpine, who taught the cultivation of corn, about the year 1383 B. C. and the inſtitution of the Eleuſinian myſteries. Erectheus reigned 50 years, and was ſlain in a battle with the Eleuſians.

ERECTHIA, in *Ancient Geography*, a municipal place of Greece, in Attica, belonging to the Egeid tribe, and deriving its name from king Erectheus. It was the native place of the orator Iſocrates.

ERECTION, the act of raiſing or elevating a thing in a right line.

The erecting of a perpendicular on a line given, is a popular problem in geometry. See Perpendicular.

The term erection is alſo uſed figuratively; as the erection of a marquiſate into a duchy; biſhoprics can only be erected by the king.

Erection, in *Phyſiology*, is the change in the ſtate of the male penis, by which that organ is rendered capable of entering the vagina of the female, for the purpoſes of ſexual intercourſe. See Generation.

ERECTOR, in *Anatomy*, a name given to two muſcles ſuppoſed to poſſeſs the power of bringing the organs with which they are connected into an erect ſtate. They are the erector penis of the male, and erector clitoridis of the female ſubject. See Generation.

ERECTUM, Folium, in *Botany*. See Leaf.

ERECTUS, Caulis, an upright ſtem. See Caulis, *n.* 6.

EREGEM, in *Geography*, a town of Flanders; 10 miles S.W. of Bruges.

EREGMOS, from ερεικω, *I break*, a word uſed by the ancients to expreſs a bean decorticated and broken into ſmall pieces, in order to be boiled in ptiſans; and alſo applied indifferently to all the leguminous fruits broken in the ſame manner.

EREKLI, in *Geography*, a town of Aſiatic Turkey, in the province of Caramania; 60 miles E. of Cogni.

EREMEGIKE, a town of Aſia, in Thibet; 25 miles S. of Tourfan.

EREMIT. See Hermit.

ERES, or Eris, in *Geography*, a town of Perſia, in the province of Schirvan, on the borders of Armenia; 80 miles S.W. of Derbend, and 120 S.E. of Teflis.

ERESIA, in *Botany*, a name given by Plumier to a new American genus, Nov. Gen. 8. t. 25, in honour of the Grecian botaniſt Theophraſtus Ereſius; but Linnæus, and all ſucceeding writers, have, with the greateſt poſſible propriety, called the plant *Theophraſta*, which ſee.

ERESMA, in *Geography*, a river of Spain, which runs into the Duero, between Simancas and Tordeſillas.

ERESÓS, in *Ancient Geography*, a town of the iſland of Leſbos, which was the native place of Theophraſtus.

ERESUS, or Ebusus, a town of the iſland of Ebuſus, founded by a colony of Carthaginians. Its harbour was commodious, its walls very large, and its houſes well built.

ERETENUS, a river of Italy, in Venetia, famous, according to Ælian, for its excellent eels, and ſuppoſed to be the preſent Retona.

ERETHISMUS, (from ερεθιζω, to *irritate*, or *excite*). Medical writers extend the general meaning of this term to every kind of irritation which has a tendency to weaken and deſtroy the vital powers.

In this article we intend to take particular notice of a dangerous affection of the conſtitution, well known among ſurgeons by the name of the *mercurial* erethiſmus.

Mr. Pearſon acquaints us, that on his firſt ſucceeding to the ſituation of ſurgeon to the Lock hoſpital, he had occaſion to remark, that almoſt every year one, and ſometimes two inſtances of ſudden death occurred among the patients of that charity. No cauſe could be aſſigned for theſe events, but the ſubjects were commonly obſerved to be men who had either nearly, or completely finiſhed a courſe of mercury. Meſſrs. Bromfield and Williams, on being conſulted by Mr. Pearſon, concerning theſe extraordinary caſes, confeſſed themſelves ignorant of the cauſe, mode of prevention, and treatment, and explained, that they had never been able to detect any diſeaſed appearances in the bodies of ſuch perſons as had died in this ſudden and unexpected manner.

Mr. Pearſon at length aſcertained, that theſe unfortunate accidents were to be aſcribed to mercury acting as a poiſon on the ſyſtem, quite unconnected with its operation as a remedy; and that its deleterious qualities were neither in proportion to the inflammation in the mouth, nor to the actual quantity of mercury abſorbed into the conſtitution. The diſordered ſtate of the ſyſtem, implied by the mercurial erethiſmus, comes on after a long employment of mercury, and tends to a fatal termination. According to Mr. Pearſon, it is characterized by great depreſſion of ſtrength, a ſenſe of anxiety about the præcordia, irregular action of the heart, frequent ſighing, partial or univerſal trembling, a ſmall, quick, and ſometimes an intermitting pulſe, occaſional vomiting, a pale contracted countenance, a ſenſe of coldneſs; but the tongue is ſeldom furred, and the vital and natural functions are not much diſordered.

Mr. Pearſon obſerves, that when theſe, or the greater part of theſe ſymptoms are preſent, a ſudden and violent exertion of the animal power will ſometimes prove fatal. Walking haſtily acroſs the ward; riſing up ſuddenly in the bed to take food; or ſlightly ſtruggling with ſome of the other patients, are circumſtances noticed by the above gentleman as having commonly preceded the ſudden death of ſuch perſons as have died of the mercurial erethiſmus.

In order to avert the perilous effects of this peculiar affection, Mr. Pearſon ſtates, that the employment of mercury is, at all events, to be diſcontinued, whatever may be the ſtage, extent, or violence of the venereal ſymptoms. Every conſideration muſt yield to the great object of extricating the patient from a ſtate of impending deſtruction; nor would a perſeverance in the uſe of mercury, under theſe circumſtances, be of any avail, in regard even to the ſyphilitic complaints.

The patient ſhould be expoſed to a dry, cool air, without being ſubjected to any more fatigue than can be avoided. Mr. Pearſon contends, that ſitting in a room with a window open is not ſufficient, but that the patient ſhould go into a field or garden, and live as much as poſſible in the open air, till the above ſymptoms have diſappeared. This plan ſhould be conjoined with a generous diet. In this way patients have often been ſufficiently relieved in the ſhort ſpace of ten or fourteen days, to re-commence the employment of mercury, and to bear its exhibition effectually, without any bad conſequences.

The gradual approach of the mercurial erethiſmus is commonly indicated (according to Mr. Pearſon's account) by paleneſs of the countenance, a ſtate of general inquietude, and frequent ſighing: the reſpiration becomes quicker, ſometimes accompanied with a ſenſe of conſtriction acroſs the cheſt; the pulſe is ſmall, frequent, and often intermitting, and there is a ſenſe of fluttering about the præcordia. In this early ſtage the further progreſs of the mercurial erethiſmus may be frequently prevented by the exhibition of the camphor mixture with large doſes of the volatile alkali, the employment of mercury being at the ſame time ſuſpended. Alſo, when the ſtomach is not oppreſſed by ſarſaparilla, this medicine is productive of infinite benefit to perſons afflicted with the mercurial erethiſmus. See Pearſon on the "Effects of various Articles of the Materia Medica in the cure of Lues Venerea," edit. 2. p. 155 to 159.

ERETRIA, in *Ancient Geography*, a town of Greece, in the Phthiotide, a country of Theſſaly.

Eretria, a town of the iſland of Eubœa, ſituated on the ſea-coaſt at ſome diſtance to the ſouth-eaſt of Chalcis, oppoſite to the mouth of the Oropus, which, on the continent, ſeparates the limits of Bœotia from thoſe of Attica. This town was probably built by the Athenians, as Strabo ſays, before, but according to Herodotus, after the war of Troy. It was for a long time a conſiderable place, and remained in a flouriſhing ſtate under the reign of Darius, ſon of Hyſtaſpes. It was deſtroyed by the Perſians in the war of Greece, but was afterwards rebuilt, became very rich, and ſubſiſted in the time of Strabo. It was amply furniſhed with pictures, ſtatues, and ſuch ornaments. We cannot trace any remains, except a perſuaſion that it exiſted in a place called by the modern Greeks *Gravelinas*.

Eretria *terra*, *Eretrian earth*, in the *Materia Medica*, the name of a very peculiar kind of alkaline bole, dug in the Negropont, near the ancient Eretria, and once in great uſe as an aſtringent and a ſudorific.

The ancient writers in medicine all mention the Eretrian earth, and Dioſcorides and Galen deſcribe two kinds of it, a grey and white. The grey is what is properly diſtinguiſhed by this name, being an earth of a different kind from all the other boles. The white, though the ancients ſeem not to have obſerved it, yet was plainly, from their own deſcriptions, the ſame with the white bole armenic, though found in a different place. Hill's Hiſt. of Foſſ. p. 5.

The grey or genuine Eretrian earth is a fine and pure greyiſh white earth, moderately heavy, naturally of a ſmooth ſurface, of a friable texture, eaſily crumbling to pieces between the fingers, but not ſtaining the ſkin in handling; it ſticks firmly to the tongue, but melts to a butter-like ſubſtance in the mouth; it burns to a perfect ſnow-white, and efferveſces violently with aqua-fortis. But what abundantly diſtinguiſhes it from all other earths is, that if a little be wetted, and drawn over a plate of braſs or copper, ſo as to mark a line, the mark will in a little time appear blueiſh. This is recorded of it ſo early as in the writings of Dioſcorides, and experiment proves it to be true. It ſeems plainly to be owing to an alkaline quality in the earth; this it plainly manifeſts by its fermenting ſo ſtrongly with acids; and it is as well known that alkalines draw a blue tincture from copper.

The ancients all eſteemed it a great medicine, and were particularly careful in their way of preparing it for uſe, by frequent waſhing. It is now unknown in the ſhops, but its highly alkaline quality, in which it is ſo much ſuperior to all the earths in uſe, might make it worth the bringing into uſe again; and it may ſtill be had in its old place, in almoſt any quantities.

ERETRIAC School, in the *Hiſtory of Philoſophy*. See Eliac *School*.

ERETRUM, in *Ancient Geography*, a town of Italy, in the country of the Sabines, N. E. of Rome, and S. W. of Cures. Strabo preciſely marks its ſituation, when he ſays that it was on the Via Salaris, and that the Via Nomentana terminated there. It was at a ſmall diſtance from the Tiber, near the 18th mile ſtone, according to the tables of Antonine and Peutinger.

EREUATIS, a town of Aſia Minor, in Lycia.

EREUM, a town in the iſland of Sardinia.

EREWASH-Canal, in *Geography*, is the parliamentary name of an important line of canal navigation, which nearly divides the counties of Derby and Nottingham for about twelve miles, of which an account has been given under our article Canal, to this it may be neceſſary to add, that by the act of the 29th George III. for Cromford canal, the tolls on this canal for all articles, except coals and coke, were lowered to one-half of thoſe mentioned in the original act, it being provided that no ſupplies of water to the canal ſhould be taken for the uſe of the Cromford canal, except at thirty feet below the ſummit level of this. Upon this canal the very important experiment was tried, at Ilkerton common, of ſuffering the coal-owners to work their coal under the canal inſtead of paying large ſums in order to have the ſame left, as the act had provided, and a great length has been thus excavated and the ground ſettled, with only a trifling and temporary inconvenience to the canal, in raiſing the banks: on the Nottingham canal the ſame was alſo ſucceſsfully tried, even under the locks, on the recommendation of Mr. Thomas Walker; ſee *Nottingham canal.* A rail-way branch conducts from the head of this canal to Beggarlea and another to Old Brinſley collieries in Nottinghamſhire; and another, conſtructed in 1808, to the new collieries in Cotmanbury-wood in Derbyſhire.

EREZEE, a ſmall town of France, in the department of the Sambre and Meuſe, chief place of a canton in the diſtrict of Marche, with a population of 640 individuals. Its canton has a territorial extent of 272½ kiliometres, 13 communes, and 4519 inhabitants.

ERFA, a town of the iſland of Corſica; 25 miles N.N.W. of Baſtia.

ERFURT, or Erfort, anciently called *Erpes,* or *Erpisfurt,* a very old town of Germany, in Thuringia, on the river Gera, 60 miles N. by E. of Coburg. N. lat. 51° 6′. It appears to have been founded in the beginning of the fifth century. The emperor Lewis held a diet at Erfurt in the year 852. The emperor Henry I. did the ſame in 935, and Rudolph I. in 1289. The laſt diet of the empire held at Erfurt was that of the year 1566. Erfurt was not an immediate free imperial city, but it enjoyed ſeveral conſiderable lordſhips and immunities, firſt under the protection of the landgraves of Thuringia, then of the princes of Brunſwick, and laſtly, from the year 1483, of the electoral houſe of Saxony: but the archbiſhops of Mentz claiming the ſovereignty over Erfurt, it was at laſt agreed, in 1667, that they ſhould keep a governor in the city, on the expreſs condition that the Proteſtant doctrine and worſhip ſhould be reſpected. The profeſſors' chairs of the univerſity, which had been eſtabliſhed in 1392, were allowed to be filled half with Roman Catholic and half with Proteſtant teachers. In 1754 an academy of ſciences was founded, to which were ſubſequently added a botanical garden, an anatomical theatre, an aſtronomical obſervatory, a riding ſchool, and a ſociety of natural hiſtory. The beſt public libraries are thoſe of the Jeſuits, of the Scottiſh convent, and of the Lutheran miniſtry, which contained ſome valuable ancient manuſcripts of the Hebrew bible.

The moſt remarkable public building at Erfurt is its cathedral church, which is reported to have been built in the year 752. Its celebrated great bell weighs 275 cwt. In more ſuperſtitious times, pilgrims uſed to flock to Erfurt from all parts of Germany on a particular day, to dance the *dance of Death* (den Todtentantz.)

At the peace of Luneville, in 1801, the city of Erfurt, its territory and dependencies, and all the rights of ſovereignty poſſeſſed by the eccleſiaſtical elector of Mentz, or Mayence, were ceded to the king of Pruſſia, as part of the indemnities to which this monarch was entitled for his loſſes on the right ſhore of the Rhine. The population of Erfurt and its territory, together with the Eichsfeld, was, in 1802, reckoned at 121,200 individuals, and in the territory of Erfurt in particular, incluſive of the town, there were 3517 individuals to the German ſquare mile. The city of Erfurt, without the garriſon, contained 16,500 inhabitants.

But Pruſſia having declared war againſt France in 1806, Erfurt was one of the firſt towns which ſurrendered to the French after the unfortunate battle of Jena or Auerſtädt, in October 1806. The fort of Peterſberg, which protects the city, and which had always been conſidered as very ſtrong, did not even attempt a defence. At the peace of Tilſit, in 1807, Pruſſia was ſtripped of all the new acquiſitions and old poſſeſſions beyond the Elbe; and Erfurt, by the conqueror's decree of the 18th of Auguſt, 1807, was to form part of the new kingdom of Weſtphalia. But the French emperor having had a conference with the emperor Alexander I. of Ruſſia at Erfurt in the month of October, 1808, this city was again transferred, by way of compliment, to the Ruſſian emperor's brother-in-law, the preſent duke of Saxe-Weimar, who is a member of the Confederation of the Rhine. There is at Erfurt a conſiderable manufacture of ribbands, which employs above 500 individuals.

ERGALIA, of εργον, *opus,* a word uſed by the *Alchemiſts,* to expreſs that part of their treatiſes which explains the inſtruments employed in their operations.

ERGANE, in *Mythology,* the *Inventreſs,* an epithet of Minerva, becauſe to her was aſcribed the invention of ſeveral arts; ſince, beſides that of the art of war, Lucian aſcribes to her that of architecture; the art of ſpinning, of making cloth, tapeſtry, ſilk and woollen ſtuffs, is alſo aſcribed to her by the ancients. She was alſo reckoned the firſt who taught man to plant and cultivate the olive. She is likewiſe honoured with the invention of chariots, and of the uſe of trumpets and the flute, &c.

ERGASIMA, a name given by Dioſcorides and other of the ancients to a very foul and coarſe kind of myrrh.

ERGASTERIUM, a word uſed by the writers in *Chemiſtry,* ſometimes to expreſs the whole elaboratory, and ſometimes that part of a furnace on which the bottom of the retort, copel, or crucible, is to reſt in an operation.

ERGASTINÆ, Εργαστιναι, in *Antiquity,* a ſelect number of virgins employed in weaving Minerva's peplos or robe, which was carried in proceſſion at the Athenian feſtival Panathanæa. See Peplos, and Panathanea.

ERGASTULUM, among the *Ancients,* a houſe of correction, or workhouſe, where ſlaves, by the private authority of their maſters, were confined, and kept at hard labour for ſome offence. It was likewiſe called ſophroniſterium.

ERGATIA, Εργατια, in *Antiquity,* a Laconian feſtival, in honour of Hercules.

ERGAVIA, in *Ancient Geography,* a town of Spain, in the Tarragonenſis. Ptol.

ERGAVICA, a town of Hither Spain, S. of Bilbilis. This appears to have been a conſiderable place when it was taken by Gracchus in his campaign. Several medals were ſtruck here, which repreſented Auguſtus and Tiberius, with an ox upon the reverſe.

ERGENE, in *Geography,* a river of European Turkey, which runs into the Mariza, near Demotica, in Romania.

ERGERS, a river of France, which runs into the Ill, about two miles eaſt from Griſpoltheim, in the department of the Lower Rhine.

ERGETIUM, in *Ancient Geography,* a town of Sicily. Ptol. and Steph. Byz.

ERGINUS, a river of Thrace, in the vicinity of the Athyras, which ran before Sarpedon.

ERGITIUM, a town of Italy, in that part of Magna Græcia called Apulia, ſituated on the Appian way, between Teanum N.W. and Sipontum S. E.

ERGOT, in the *Manege,* is a ſtub, like a piece of ſoft horn, about the bigneſs of a cheſnut, placed behind and below the paſtern joint, and commonly hidden under the tuft of the fetlock. To diſ-ergot, or take it out, is to cleave it to the quick with an inciſion-knife, in order to pull up a bladder full of water that lies covered with the ergot. This operation is ſcarcely practiſed at Paris, but in Holland is frequently performed upon all four legs, with intent to prevent watery ſores and foul ulcers.

ERGOT, in *Agriculture*, is a vegetable diſeaſe which affects different ſorts of grain, and other crops, ſhewing itſelf, according to the author of Phytologia, by the ſeeds growing out into large horns, having a black appearance without, as in ſea-cale, rye, and in carex. It very often attacks the rye in France, and occaſionally in this country in ſuch ſeaſons as are very moiſt; the grain in theſe caſes becoming conſiderably elongated, being either ſtraight or crooked, containing a black meal along with the white; and is aſſerted to have the appearance of being pierced or perforated by inſects, which are believed by ſome to be the cauſe of the affection. It has frequently other different appellations, ſuch as clavus, or the ſpur, and horn ſeed. No certain remedy or method of preventing it has, we believe, been yet diſcovered. See next article.

ERGOT, in *Medicine*, a term originally applied, as we have ſeen, to a peculiar diſeaſe of corn, eſpecially of rye, from the reſemblance of the grains thus affected, to the ſpur of a cock: and, by metonymy, uſed to denote a diſeaſe in the human body, occaſioned by taking this diſeaſed, or *ergoted* rye as food.

The earlieſt account of this diſeaſe of rye, and of its pernicious influence on the human body, with which we are acquainted, is contained in a letter from M. Dodart to the editor of the Journal des Savans, publiſhed in March, 1676. (See vol. iv. part ii. p. 79.) The facts were communicated a few years before by the phyſicians and ſurgeons of Sologne, in which diſtrict the diſeaſe had been very prevalent. The grains of rye, affected by the ergot, according to M. Dodart, are of a blackiſh colour externally, but white within, and when dry, they are harder and of a more compact ſubſtance than the natural grains, and have no bad taſte. They are conſiderably longer than the other grains, ſome of them being fourteen or fifteen lines in length, and two in breadth; and ſeven or eight of them are ſometimes ſeen in one ear. They are obviouſly not foreign ſubſtances engendered between the grains of rye, M. Dodart adds, but the true grains, ſurrounded with their proper coats, in which the place of the germ is diſcernible. Theſe grains were called *ergots*, *ſpurs*, in Sologne; in Gaſtinois, where they alſo were known, they were termed *bled cornu*. In various other places this diſeaſed rye has been called ſecale cornutum, or corniculatum, ſecale luxurians, clavus ſecalinus, mater ſecalis, or *mutterkorn*, (by the Germans), &c. It is ſtated by Tiſſot, on the authority of Haller, that the ergot affects rye only, or two or three other Alpine plants of the graſs-kind. (See Philoſ. Tranſact. vol. lv. for 1765, p. 110. A minute deſcription of the ergot was publiſhed by C. N. Langius in 1717, the ſubſtance of which may be found in the Acta Eruditorum for 1718, p. 309.)

The learned Tiſſot, in his letter to ſir George Baker, juſt referred to, ſtates that there are two other diſeaſes which affect rye and wheat, and which have been confounded with each other, as well as with the ergot, or ſecale cornutum, *viz.* the *rubigo*, or mildew, and the *uſtilago*, *bruſure*, or blight; the former being characterized by the appearance of a reddiſh yellow powder, of a glutinous nature, adhering to the ſtalk and head of the corn; and the latter by a blackneſs and degeneration of the corn. (See Fontana on this ſubject, and ſir Joſ. Banks on the diſeaſes of corn.)

The ergot was particularly obſerved in rye in wet ſeaſons, and more eſpecially when a wet ſpring was ſucceeded by exceſſive heat. M. Dodart remarks that the bread, which was made of ergoted rye, did not differ from ordinary bread in point of taſte; that this rye was moſt particularly pernicious when new; but that its effects were not obſerved until it had been eaten for a conſiderable time. M. Noel affirms that it loſes its deleterious qualities altogether after being kept a few months in ſheaf. (See a letter in Queſnay's Traité de la Gangrène, ſeche, p. 407, Paris, 1749.) And writers in general agree in ſtating, that the diſeaſe, which the ergoted rye induces, is prevalent only at the concluſion of harveſt, and ceaſes before the commencement of winter; and that it was chiefly obſerved among the poor, who were unable to procure wheaten bread in thoſe ſeaſons of humidity and ſcarcity. (See Muller in Comment. Lipſiæ, anno 1752, p. 634, &c.)

The ſymptoms of the ergot in the human body are deſcribed ſomewhat differently by different writers; but they coincide in repreſenting a dry gangrene, and ultimately death, as the ordinary reſults of the diſeaſe. It commences with a laſſitude and debility, but with little interruption to the functions in general. A degree of torpor in the lower extremities is then obſerved, accompanied, according to ſome of the writers, with a ſenſe of prickling, and of the creeping of inſects (formicatio) upon the ſkin; a ſlight degree of ſwelling, but without inflammation, enſues, often accompanied by the moſt excruciating pains, and with a ſenſe of burning heat; ſoon ſucceeded by that of extreme cold; the ſkin of the feet and legs becomes ſhrivelled, and of a dark hue, as if dried in ſmoke, afterwards black and deſtitute of feeling; in fact the limb dies, or is gangrenous, but in a dry ſtate, which has been compared to that of a mummy. By degrees the dead parts ſeparate from the living, as if they had been deſtroyed by cauſtic. In this mutilated condition, deprived of one, ſometimes of both legs, more rarely of the hands or arms, ſome individuals have ſurvived for months, or even years.

Beſides this ſpontaneous gangrene of the limbs, another ſpecies of diſeaſe has been aſcribed to the uſe of *ergoted* rye by Hoffmann, Tiſſot, and ſome other writers; but with what juſtice or propriety may perhaps admit of a queſtion. The diſeaſe alluded to was a febrile diſeaſe, ſaid to be of a contagious and malignant nature, and to be accompanied and principally characterized by various ſpaſmodic and convulſive ſymptoms, by which, or by a general epilepſy, the patients were frequently carried off. This diſeaſe is ſaid to have been epidemic in Heſſia, Weſtphalia, and other parts of Germany, at ſeveral different periods, in the 16th and 17th centuries; and a deſcription of it by the profeſſors of the univerſity of Marpurg, in the year 1597, is generally referred to, as the firſt complete account of the diſeaſes. But in that account, of which a tranſlation is given by Gregorius Horſtius, no alluſion whatever is made to the ergot, or ſecale cornutum; bad bread is mentioned only among other ſorts of crude and unwholeſome aliment, to which the diſeaſe (occurring in a time of dearth) is there aſcribed. The whole of what is ſaid reſpecting the exciting cauſes of that epidemic is contained in the compaſs of theſe few lines. "Cauſas hujus affectus quod attinet, ex ægrotantium relatione ſcire licet, quod externa cauſa communiter in alimento, ad nutriendum minus idoneo et improportionato, conſiſtat, dum pauperes rebus ad vitam neceſſariis deſtituti, panem impurum et male coctum longo tempore, in ſummâ famis urgentiâ, devorant, interdum etiam poma acerba et auſtera, fungoſque et ſimilia deglutientes, ſeſe eduliis crudis, immaturis, et aſtringentibus ingurgitant, de quorum depravatâ concoctione cruditates obortæ, &c." (See Greg. Horſt. Opera, vol. ii. lib. viii. obſ. xxii.) A ſimilar ſtatement, reſpecting the origin of this epidemic, is given by Sennertus in his chapter, "De febre Malignâ cum Spaſmo," probably upon the authority of the Marpurg profeſſors. The diſeaſe he ſuppoſed to be excited by a malignant vapour or humour, vellicating the brain and nerves. "Malignus autem ille vapor et humor ortum habuit ex victu pravo, dum, ob annonæ caritatem, panem non bonum, fructus corruptioni obnoxios, fungos, et id genus alia, ad explendam famem, pauperes devorabant. Ex quo victu pravo vitioſos humores in corpore colligi neceſſe eſt, &c." (Sennert. de Febribus, lib. iv. cap. 16.) The diſeaſe, therefore, is obviouſly conſidered by the original writers as originating from defect of nutritious food, and the ergot is not in any way alluded to. The ſymptoms of this fever, which was called by the Germans *die kriebel-kranckheit, oder ziehende ſeuche*, the convulſive peſtilence, are thus briefly enumerated by Hoffmann. "The diſeaſe in its commencement occupies the limbs and the extremities of the hands and feet, in which a ſenſe of formication is felt. In ſome inſtances it begins with ſickneſs and vomiting. Then follow violent ſpaſmodic contractions of the fingers and toes, which at length alſo attack the knees, ſhoulders, elbows, and even the face, eyes, and lips, accompanied by an intolerable pain, and ſometimes with a ſenſe of extreme coldneſs, ſometimes with that of a burning heat. Theſe ſymptoms return at ſtated periods, and ſometimes continue for ſeveral weeks. As the pains diminiſh, the patients fall into a ſtate of drowſineſs and torpor, often into an alienation of mind, and are affected with giddineſs and deafneſs, the limbs remaining ſtiff, and deſtitute of the power of motion. In the extremities of the limbs large veſicles, filled with ſerum, often appear, and ſometimes other tumours, which paſs into a gangrenous condition, but by a very ſlow progreſs, by which ultimately even the bones have been gradually deſtroyed. A ſtate of general convulſion, or epilepſy, occaſionally ſupervenes, and proves fatal, eſpecially in children." (Hoffmann. Med. Rat. vol. ii. par. ii. cap. 9. § xvi.) A more detailed account of the ſymptoms is given by Sennertus, loc. cit. Dr. Cullen has followed Linnæus and Vogel in denominating this diſeaſe *Raphania*; (See Amœn. Academ. vol. vi.) but queſtions whether it be the ſame diſeaſe as the *Necroſis uſtilaginea*, by which term Sauvages has deſignated the ergot. (See Cullen Noſol. Meth. gen. 52. Sauvage Noſol. Meth. claſs x. gen. 39.) There is, in fact, much confuſion in the accounts of authors upon this ſubject; and it ſeems probable that the true effects of the ergoted rye are to be found only in the dry gangrene, and not in the epidemic fevers, which have been aſcribed to it.

It was long ago known that corrupted corn was poiſonous to the animal body. Galen remarked, that the ſeeds of colium temulentum mixed with wheat, or the degenerated grain, called black wheat, would produce fever, head-ache, delirium, and gangrenous ulcers. (De Aliment. facultat. lib. i. cap. 37.) Moſt of the writers on the ſubject, from M. Dodart downwards, have ſtated, that the ergoted rye, when given to fowls, hogs, and other animals, as food, produces the ſame ſymptoms as in man, and deſtroys life. More lately the Abbé Teſſier made a ſeries of experiments upon this ſubject, and has given a minute deſcription of the ergot in rye. He found that by feeding or cramming turkies and other animals with this diſeaſed rye, he could produce in all of them the dry gangrene and death. (See Memoires de la Soc. Roy. de Medecine for 1776, p. 303. Hiſt. de l'Acad. des Sciences for 1710. Acta Erudit. Lipſ. 170 et 1752. Saviard Obſ. Chirurg. The Treatiſe of M. Teſſier, &c.

The dry gangrene occurs from other cauſes than the ergoted rye. An account of a whole family conſiſting of eight perſons, who were ſeized and mutilated or deſtroyed by gangrene of the lower extremities, preceded by pain and ſome ſwelling, at Wattiſham in Suffolk, is given in the Philoſ. Tranſ. vol. lii. part ii. The ſtate of the family, three months after the commencement of the diſeaſe, is thus repreſented: "1. Mary, the mother, æt. 40. The right foot off at the ancle; the left leg mortified, a mere bone, but not off. 2. Mary, æt. 15. One leg off below the knee; the other perfectly ſphacelated; but not yet off. 3. Elizabeth, ætat 13. Both legs off below the knees. 4. Sarah, æt. 10. One foot off at the ancle. 5. Robert, ætat. 8. Both legs off below the knee. 6. Edward, ætat 4. Both feet off at the ancles. 7. An infant, four months old, dead." The father alſo ſuffered ſlightly in the fingers. Although the ſymptoms were exactly thoſe of the ergot, yet, in this caſe no rye was eaten, nor could any other circumſtance in the diet or economy of the family be diſcovered, to which the gangrene could be attributed. See GANGRENE.

ERIACH, in *Antiquity*, the name of a recompenſe aſſigned by the Iriſh Brehon law, in caſe of murder, to the friends, or to the child or wife of him that was ſlain, as a kind of compoſition between the murderer and his proſecutors.

ERIAMBO, in *Geography*, a river of Ruſſia, which runs into the Oby; 30 miles above Obdorokoi.

ERIANTHUS, in *Botany*, from εριον, *wool*, and ανθος, *a flower*, Michaux Fl. Boreali-Amer. v. 1. 54. A genus of graſſes eſtabliſhed by Michaux, in its character very near *Saccharum*, but more naturally allied to *Andropogon*, to which, if the character of that genus were reformed, Michaux himſelf ſuſpects the preſent might be referred. *Andropogon* indeed ſeems to require a thorough inveſtigation, and probably a diviſion into more than two genera.

ERIBANUM, in *Ancient Geography*, a town of Italy, in Campania, upon the Vulturnus. Polybius.

ERIBŒA, a town of Macedonia, in the country of the Parthæans. Ptol.—Alſo, a mountain of Macedonia, in the ſame country.—Alſo, a town of Aſia, in Bithynia.

ERIBOLUM, the port of Nicomedia, a town of Bithynia.

ERIC, king of Denmark, in *Biography*. There were ſeveral princes of this name, though but few of them have any claim to notice in this place. Eric the Firſt was poſſeſſed of ſo many virtues that he was ſurnamed the "Good." A muſician, celebrated for his great ſkill on the harp, aſſerted that he could deprive his hearers of their underſtanding by the powers of his inſtrument. Eric challenged him to the trial, and in the paroxyſm of phrenzy into which the performer threw the monarch, he killed four of his guards. Grieved at what he had done, he made all the recompenſe he was able to the relations of the deceaſed, and to do penance for the bloody deed, he determined to undertake a pilgrimage to the Holy Land. His ſubjects remonſtrated againſt his deſign, but he was not to be diſſuaded from his purpoſe, ſet out on his journey, and died at the iſle of Cyprus. This event took place in the year 1107.

ERIC X., king of Sweden and Norway, as well as of Denmark, the ſon of Wratiſlaus VII. duke of Pomerania, was declared ſucceſſor to the crowns of Denmark and Norway in the year 1388, by his great aunt, queen Margaret; and when, in 1396, ſhe annexed the crown of Sweden to her dominions, Eric was, by the treaty of the "Union of Calmar," declared ſucceſſor to that alſo. This celebrated treaty conſiſted of three articles 1. "That the three kingdoms of Denmark, Sweden, and Norway, ſhould thence forward have but one king, who ſhould be choſen alternately by each of them, and approved in a general aſſembly. 2. That the monarch ſhould divide his reſidence equally between the three kingdoms, and appropriate the revenues of each to its particular exigencies. 3. That each kingdom ſhould retain its own laws, cuſtoms, ſenate and privileges; and that the ſubjects of the one ſhould not be elevated to offices of profit or power in another." Theſe conditions ſeemed, at firſt ſight, to have been dictated by wiſdom, but they proved to be the ſource of wars that continued to rage during a whole century between the three kingdoms. On the death of the queen in 1412, Eric ſucceeded without oppoſition to the three united crowns. He had married the daughter of Henry IV. king of England, with whom he had a large portion, and thus might be regarded as one of the moſt potent kings of his time. Eric was ſoon involved in a war with the princes of Holſtein, which for ſome time was carried on with doubtful ſucceſs, but in 1424 the whole of South Jutland, including Sleſwick and Gottorp, was adjudged to the Daniſh crown. This award, which was made by the emperor Sigiſmund, at Buda, determined Eric upon a pilgrimage to the Holy Land. During the expedition, he was made captive, and obliged to pay a large ranſom for his liberty. His abſence from home was attended with other evils. From his acceſſion he had diſpleaſed the Swedes by refuſing to call a general diet for the confirmation of their liberties, which excited much diſcontent, that at length broke out into open rebellion. In 1435 he met the Swediſh diet at Stockholm, and agreed to a full redreſs of grievances. His promiſes, however, were of little avail to his people, who, after enduring much from his miſconduct, depoſed him in 1439, and choſe, in his ſtead, his nephew Chriſtopher of Bavaria. For ten years he made many attempts to regain his ſituation, but without ſucceſs. After this he employed himſelf in compiling a hiſtory of Denmark from the public regiſters, comprizing the period from the commencement of the monarchy to 1288. He afterwards repaired to the iſle of Rugen, where he died in 1459. Eric poſſeſſed quick natural parts, and was a lover of learning; but he was ambitious, deſpotic, irreſolute, and inſincere, qualities which led him into many difficulties, and which rendered his reign truly diſaſtrous. Univer Hiſt.

Eric XIV., king of Sweden, ſon of Guſtavus Vaſa, aſcended the throne of Sweden in 1560, at the age of twenty-ſeven, and was poſſeſſed of all the accompliſhments proper to his elevated ſituation. He ſpoke the modern languages, danced gracefully, ſhewed animation in all his actions, and was eloquent and polite. But he ſuffered himſelf to be hurried away with guſts of paſſion, which ſometimes obliterated every trace of reaſon, and rendered him furious. His father, who had witneſſed theſe fits of rage, had once formed the deſign of excluding him from the throne, and of conferring the crown on his ſecond ſon. For the ſame reaſon he refuſed to permit him to viſit England to pay his court to the princeſs (afterwards queen) Elizabeth: but negotiated the buſineſs by means of his ambaſſador and ſecond ſon John. Eric, however, almoſt immediately after his acceſſion, determined to obtain an interview with Elizabeth, and ſet ſail with a large fleet and ſplendid train, but the veſſels being overtaken by a violent ſtorm, were driven back upon his own coaſt, where he ſuffered ſhipwreck, and for a time relinquiſhed his matrimonial project. He next ſent propoſals of marriage to Mary queen of Scotland, and almoſt before he could obtain any anſwer, ſolicited from the emperor the hand of the princeſs of Lorraine, daughter of Chriſtian II. with whom he was enamoured by the deſcription of ſome of his courtiers. He received a favourable anſwer, but in the mean time he had changed his mind in favour of Elizabeth. His political conduct was as capricious as his amours, and involved him in continual quarrels with his neighbours, and a confederacy was formed againſt him by Muſcovy, Poland, Denmark, and Lubeck. His brother John, who had married Catharine, daughter of the king of Poland, fell under his ſuſpicion, and was driven to an open rupture. John was cited to Stockholm, to vindicate his conduct, and refuſing to appear, an army was ſent into Finland with orders to ſeize him and his wife, and to bring them to the capital. He was immediately thrown into priſon, accompanied by his wife, who voluntarily choſe to ſhare in his ſufferings. It is ſaid that the king went frequently to the priſon with the deſign of murdering his brother, but that on ſeeing him he felt his heart ſo moved with pity, as to prevent him from ſtriking the fatal blow. Sometimes with tears in his eyes he would confeſs the ſanguinary deſign which had prompted his viſit, and added, "I know that the crown of Sweden is intended for you, and I requeſt that, when you are in poſſeſſion of it, you will pardon my errors." This circumſtance ſtrongly diſplays the violence of contending paſſions in the mind of Eric, and has been brought to prove his inſanity.

The early years of his reign were ſpent in wars chiefly with Denmark, carried on with vigour on the part of Eric, though without any permanent advantage. Domeſtic troubles at length withdrew his attention from foreign wars, and his capricious conduct deſtroyed all reſpect for him in the breaſts of his ſubjects. Diſappointed in his matrimonial projects, he entertained a number of concubines, one of whom, a peaſant's daughter, gained ſuch an aſcendancy over him that he married her. He was under the influence of his miniſters and domeſtics of mean rank, who frequently excited his jealouſies of the great families. He entertained a particular hatred of the Stures, an illuſtrious family, deſcended from the ancient regents. Eric had taken one of them into favour, though he had, on a former occaſion, diſgraced him, and made him contemptible in the eyes of the populace. He now ſent him in the quality of embaſſador to Stralſund, but he became once more the object of the king's abhorrence, who conceived that he was conſpiring againſt his life and crown. The king took pains to convince the ſtates that Sture carried on dangerous intrigues at Stralſund, and he ſuborned witneſſes to accuſe him of treaſonable deſigns. An infamous favourite, named Peerſon, perſuaded Eric to extirpate the whole family; ſentence of death was accordingly pronounced againſt thoſe unfortunate men, together with twenty-ſix nobles, who were the pretended accomplices of a conſpiracy laid to their charge. A public trial was afterwards allowed them, in which the Stures were able to vindicate their cauſe ſo completely, and to prove their innocence ſo undeniably, that the king himſelf apologized to them for their detention and long impriſonment: nevertheleſs, in a very ſhort time, he ſtabbed Nils Sture with his own hand. The unfortunate man drew the dagger from his breaſt, and preſented it to the monarch, who, with the moſt ſavage barbarity, ordered his guards to accompliſh that which he had failed to perform himſelf. The reſt of the priſoners were alſo cruelly murdered at the ſame time. No ſooner was this bloody ſcene over than Eric felt the pangs of a wounded conſcience. He grew frantic, and, as if purſued by the avenging furies, fled into the woods, where he wandered for many days like a wild beaſt, refuſing to take food or repoſe. On his return he endeavoured to compenſate for his cruelty, by beſtowing large ſums upon the friends and relations of the victims; and by giving up Peerſon to the hands of juſtice, who was condemned but not executed. Being threatened by the king of Denmark, Eric ſet at liberty his brother John, to whom and to his other brother he propoſed aſſigning lands in Livonia, in lieu of thoſe left them by their father Guſtavus. Shortly after he formed a deſign of putting them to death, and of conciliating the friendſhip of the czar of Muſcovy, by delivering him the wife of duke John, to whom that prince had paid his addreſſes before her marriage. His intentions were diſcovered in time to defeat the purpoſe, and the brothers began to raiſe forces in their own defence. Eric made a ſtand, and an accommodation was effected, but by the treaty he bound himſelf to give up Peerſon, his favourite, who, being put to the torture, confeſſed a plot contrived by himſelf and the king, of pillaging Stockholm, burning part of the ſhips in the harbour, and proceeding with the reſt loaded with ſpoil to Narva. The dukes now felt themſelves juſtified in breaking the treaty, and they obliged Eric to capitulate in the citadel. He was put under confinement, ſolemnly depoſed by the ſtates, and duke John elected in his ſtead. His children were declared incapable of ſucceſſion, and himſelf was condemned to perpetual impriſonment. His keepers were appointed from among the relations of thoſe whom he had cruelly maſſacred, and who did not fail to ſubject him to various inſults and indignities, and not unfrequently to the evils of cold and hunger. After nine years impriſonment, he finiſhed a wretched life in 1578, in conſequence, it was ſuppoſed, of a doſe of poiſon adminiſtered by order of his brother John, who dreaded the poſſibility of his being liberated, and again ſet upon the throne. Eric was not deficient in talents; and he poſſeſſed great perſonal bravery: under his conduct the Swediſh troops repeatedly diſtinguiſhed themſelves in contending with and overcoming the Daniſh armies, and it has been thought that he would never have ſubmitted to the hard conditions which Denmark at length impoſed on his ſucceſſor. (See JOHN.) Univer. Hiſt.

ERICA, in *Botany*, ερεικη of Dioſcorides, the ſame name, variouſly corrupted, being applied to the ſeveral ſpecies of this genus among the modern Greeks at preſent, according to Dr. Sibthorp. See Prod. Fl. Græc. 256, 257.—Heath or Ling.—Linn. Gen. 192. Schreb. 258. Willd. Sp. Pl. v. 2. 356. Ait. Hort. Kew. v. 2. 14. Sm. Fl. Brit. 417. Mart. Mill. Dict. v. 2. Juſſ. 160. Gærtn. t. 63. Tourn. t. 373. Claſs and order, *Octandria Monogynia.* Nat. Ord. *Bicornes,* Linn. *Ericæ,* Juſſ.

Gen. Ch. *Cal.* Perianth of four ovate-oblong, permanent, upright, often coloured leaves. *Cor.* of one petal, permanent, four-cleft, regular, with an ovate or cylindrical tube, more or leſs inflated. *Stam.* Filaments eight, capillary, equal, inſerted into the receptacle; anthers cloven at the ſummit, opening by two pores, by which they laterally cohere while young. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, ſtraight, longer than the ſtamens; ſtigma capitate, in four or eight lobes. *Peric.* Capſule roundiſh, ſmaller than the calyx, which covers it, of four cells and four valves. *Seeds* numerous, affixed to the columella.

Eſſ. Ch. Calyx of four leaves. Corolla four-cleft. Stamens inſerted into the receptacle. Anthers with two pores. Capſule ſuperior, of four cells. Seeds numerous.

Obſ. Some ſpecies appear to have a double calyx, but the lowermoſt was by Linnæus latterly eſteemed rather of the nature of bracteas. The ſhape of the corolla is extremely different in different ſpecies, its tube being in ſome globular, in others ovate, in others again cylindrical and much elongated; ſometimes dilated at the orifice, ſometimes contracted, in ſome inſtances curved. The anthers, either included within the tube or projecting beyond it, are in ſome ſimply cloven at the top, without any appendage at the baſe; in ſome this latter part bears a pair of briſtles, in others a pair of notched leaflets, termed a creſt, which, as Mr. Saliſbury remarks, originate rather from the filament than from the anther.

This extenſive and moſt elegant genus is confined to Europe and the ſouthern part of Africa, the country about the Cape of Good Hope being, of all others, moſt abundant in Heaths, whence the green-houſes of Britain are continually ſupplied with new ſpecies or varieties, to the great profit of nurſerymen, ſome of whom find it worth while to keep a collector reſident there. No *Erica* is found in America, in New Holland, nor ſcarcely in the Torrid Zone. The habit of the whole genus is ſhrubby, very rarely arboreſcent, with ſmall, oppoſite or whorled, uſually narrow, leaves, and bracteated ſtalked flowers, whoſe colours partake of all the moſt exquiſite tints of red, purple, yellow or orange, occaſionally variegated with green or white. Some are entirely white, but the anthers are commonly dark brown or purpliſh.

It is difficult to gueſs at the number of the real ſpecies of *Erica.* Willdenow has 137, ſome of which are duplicates. Our gardeners reckon about 300, many of which are merely varieties, but there are ſeveral others only known hitherto in a dried ſtate, and probably not a few yet remain to be diſcovered in the wilds of ſouthern Africa.

The greater part bloſſom with us in the ſpring, but many at various ſeaſons. They are for the moſt part inodorous, though a few of them are delightfully fragrant. They commonly keep well in an herbarium, provided they are dried ſuddenly, ſo as not to throw off their leaves during the proceſs.

Few good figures of this genus, except of the European kinds, are found in the older botanical works, but many appear to great advantage in the more recent works of Ventenat, Wendland, Curtis's Botanical Magazine continued by Dr. Sims, and eſpecially in a folio publication by Mr. Andrews, entirely devoted to the ſubject, as well as an octavo one, equally uſeful, by the ſame artiſt. The moſt ſuperb of all, however, are two thin faſciculi, publiſhed by Mr. Aiton, of coloured plates by Mr. Frederick Bauer, but unhappily without any deſcriptions or even ſpecific characters.

In the ſcientific definition of the ſpecies of *Erica* much yet remains to be done. The labours even of Linnæus and Thunberg are very far from perfection. Mr. Saliſbury, who has paid much attention to the ſubject, has given an arrangement of 246 ſpecies, according to their natural affinities, in the ſixth volume of the Linnæan Society's Tranſactions, with often expreſſive, if not claſſical, ſpecific characters, but with an unlicenſed change, and frequent perverſion, of names. This writer includes the Linnæan genus *Blæria,* like Thunberg, under his *Erica,* while he excludes *E. vulgaris* as a genus, by the name of *Calluna,* and ſeparates a few ſpecies (which have an irregular calyx, and fleſhy fruit, with three cells and three ſeeds) into another genus, named, from its large ſtigma, *Salaxis.* To him we are indebted for remarking that the corolla of *Erica* is permanent, which is not the caſe in *Andromeda* and *Menzieſia,* and that the anthers are united laterally to each other by their pores before they diſcharge the pollen. He alſo conſiders all true *Ericæ* as having the partitions of the fruit originating from the centre of each valve.

Linnæus and his followers diſtribute the ſpecies of this genus into three principal ſections by the ſtructure of the anthers; firſt, anthers ariſtated or furniſhed with a pair of briſtles at their baſe; ſecondly, anthers creſted, as above deſcribed; thirdly, anthers ſimple, or deſtitute of any of thoſe appendages. The latter are ſubdivided into ſuch as have the anthers included within the corolla, and ſuch as have them projecting beyond its border. All theſe ſections are moreover ſeparated into ſubordinate ones by the ſituation of the leaves, whether oppoſite, or in three, four, or more rows, or ſcattered, of which laſt *E. glutinoſa* is perhaps the only example. All theſe characters, however combined, unfortunately prove but artificial, ſeparating ſpecies naturally allied to or reſembling each other; nor are ſome of them, derived from the creſted anthers, or number of leaves, conſtant or invariable, even in the ſame ſpecies. Still, as no natural ſubdiviſions have yet been ſuggeſted, we may be glad of artificial and imperfect ones in ſo vaſt a genus. Mr. Saliſbury, though he diſpoſes the ſpecies in order, according to what he conceives to be their natural affinity or reſemblance, eſpecially in the form and proportion of the corolla, has not attempted to define or characterize many ſubdiviſions of the genus. As, however, it is very inſtructive to contemplate the ſpecies of ſuch a genus in this light, and as this writer's is the only attempt of the kind, we ſhall give examples of each of his ſubdiviſions in the order in which he places them. It is neceſſary to premiſe that theſe ſubdiviſions are conſidered as having in general no peculiar connection, and that one or more ſpecies often come between two of them, almoſt equally diſtinct from both and from each other. Thus, in the very beginning, *E. ſcoparia*, (E. coris folio quarta; Cluſ. Hiſt. v. 1. 42. f. 3.);—and *E. ſpiculifolia*, (Sm. Fl. Græc. Sib. t. 353. Prod. v. 1. 257.); ſtand as diſtinct from each other, and from three ſpecies immediately following them, among which are *abſinthoides* of Linnæus;—and *ſetacea*, Andrews, t. 62.—Next come *planifolia*, Linn. (Pluk. t. 347. f. 1.) and *oxycoccifolia* of Mr. Saliſbury, agreeing in their ovate dilated leaves, in which they are very unlike their neighbours. Then again *ſtrigoſa*, Ait. Hort. Kew. v. 2. 17;—and *ſicæfolia*, Saliſb. (rather *ſicifolia*), a new ſpecies, each ſtand ſeparate, as not immediately allied to any other.—We ſhall, in ſeparate paragraphs, mention one or more ſpecies of Mr. Saliſbury's ſubdiviſions, noticing likewiſe the ſeparate anomalous ſpecies, and introducing two or three new ones, to the beſt of our judgment, according to their ſeveral affinities. Many ſtill unſettled remain in every collection.

After *ſicifolia* follows an aſſemblage of eight ſpecies. Among theſe is *E. pubeſcens*, Linn. Sp. Pl. ed. 2. 506, *pallida* of Mr. Saliſbury, thus characterized by him.—Leaves three in a whorl. Anthers creſted, included. Flowers terminal. Leaves linear. Sides of the calyx doubled back. Corolla two lines long, downy on both ſides. Creſts ſhort.—Alſo *E. urceolaris*, Berg. Cap. 107. Ait. and Bau. Ic. t. 16. (*pentaphylla*, Linn.)

Then 13 ſpecies with little or no affinity to each other, among which are *arborea* (E. coris folio prima; Cluſ. Hiſt. v. 1. 41.); and *Thunbergii*, Linn. Suppl. 220, Curt. Mag. t. 1214, a moſt beautiful ſpecies, conſpicuous for its globoſe white tube and large deep-orange limb, very rare at preſent in the gardens.

Next appears a collection of eight, among which is *melanthera*; another of three, including *capitata* and *bruniades* (Andr. t. 61.); and a third of 18, amongſt which are *ſexfaria*, Ait. and Bau. Ic. t. 11, with *nigrita* of Linn. and Thunberg, ſo called from its conſpicuous dark anthers, elegantly contraſted with the white corolla and calyx. This laſt Mr. Saliſbury is pleaſed to denominate *volutæflora*. Theſe three ſubdiviſions he indicates as not ſo diſtinct or diſſimilar as moſt.

The following ſection compriſes five new ſpecies of Mr. Saliſbury's, named by him *fabrilis*, *dianthifolia*, *brevifolia*, *chlamydiflora*, and *ſelaginifolia*. They have all creſted included anthers, and terminal flowers.

His *pannoſa*, with a woolly corolla, ſtands alone.

Then follow 15 ſpecies, moſtly *Blæriæ* according to Linnæus, having but four ſtamens; ſee Blæria. Nor can we much object to the union of theſe two genera, except that in ſo vaſt a tribe, we may be glad of even ſo ſlight a circumſtance as number to make a genus, when there is moreover ſuch a difference in habit as this very arrangement of Mr. Saliſbury's implies. If indeed a few ſpecies of *Erica*, here and there in the different natural ſubdiviſions, were tetrandrous, nobody would think of ſeparating them for ſuch a reaſon.

E. nudiflora, Linn. Mant. 2. 229. Sm. Plant. Ic. t. 57, (accompanied by two others) follows. Mr. Saliſbury exults in having diſcovered its bracteas, which eſcaped Linnæus, Dryander, and the author of the preſent article, who in this inſtance readily ſubmits to his correction. They are in the form of two or three exceſſively minute woolly ſcales, near the baſe of each flower-ſtalk.

The next five, or rather we would ſay ſeven, uniting two of Mr. Saliſbury's ſections, are *herbacea*, Linn. Sp. Pl. 501, Curt. Mag. t. 11, not at all different from *carnea*, Sp. Pl. 504; (this, according to Dr. Sibthorp, is the genuine ἐρείκη of Dioſcorides, extremely common every where in Greece);—*mediterranea*, Linn. Mant. 2. 229, Curt. Mag. t. 471;—*multiflora*, Sp. Pl. 503, (Garidel. t. 32.), another beautiful native of the ſouth of Europe, long confounded with *vagans*;—*manipuliflora*, Saliſb. (Sm. Fl. Græc. Sibth. t. 352.);—*vagans*, Linn. Mant. 2. 230, (Engl. Bot. t. 3.) common on all the heaths of Cornwall, either with red, fleſh-coloured, or white flowers;—*umbellata*, Linn. Sp. Pl. 501, (Ait. and Bau. Ic. t. 5.);—and laſtly *nutans*, Wendland. Eric. faſc. 3. 5.—The native country of this laſt we know not, nor have we ſeen Wendland's publication. The reſt of this very natural aſſemblage grow in Europe only.

Filiformis and *turgida*, Saliſb. we have not aſcertained to our ſatisfaction.

Nine ſpecies, very naturally allied, having exceſſively long anthers, projecting from an elongated tubular corolla, are placed next. Among theſe are *E. Plukenetii*; *Petiveri*; *Bankſii*, Andr. t. 26; *Sebana*, Dryand. in Ait. and Bau. Ic. t. 10; &c. moſtly familiar to collectors.

Nine more comprehend *imbricata*, Linn. Sp. Pl. 503;—and *flexuoſa*, Andr. Eric. t. 33;—with *leucanthera*, Linn. Suppl. 223;—and *milleflora*, Berg. Cap. 96, which laſt name is well retained by Mr. Saliſbury, in preference to the inaccurate one, *paniculata*, given by Linnæus.

An aſſemblage of ſix more contains the beautiful *baccans* Linn. Mant. 2. 233. Curt. Mag. t. 358, a good ſpecimen of the reſt.

Five following ones are ſuppoſed to be little, if at all, related. Among them are the beautiful *glauca*, Andr. t. 47. Curt. Mag. t. 580; in the ſame ſection with which the *elegans*, ibid. t. 966, ſhould be inſerted. The flowers of the latter are larger, and differently coloured, but they cloſely agree in ſtructure with thoſe of *glauca*.—*E. Monſoniæ*, Dryand. in Ait. and Bau. Ic. t. 7, (E. Monſoniana; Linn. Suppl. 223.), one of the moſt magnificent of all, is placed by Mr. Saliſbury, with a ſign of incomplete affinity, after *glauca*.—*E. halicacaba*, Linn. Sp. Pl. 507, Ait. and Bau. Ic. t. 2, follows alone. Its corolla is of a pale uniform yellowiſh green.

Ten ſpecies, with a long tubular corolla and ſhort included anthers, are needleſsly, we think, divided into three parcels. Theſe are moſtly handſome flowers, very frequently to be ſeen in gardens. Among them are *verſicolor*, Andr. t. 12, which comprehends as a variety his *coſtata*, t. 46;—*diſcolor* of the ſame author, t. 3;—*cruenta*, Ait. and Bau. Ic. t. 13;—*abietina*, Linn. Sp. Pl. 506, (*E. Patterſonia* of Andr. t. 7, and the gardeners), remarkable for its thick-ſet leaves and crowded golden bloſſoms, as well as its pulpy ſeed-veſſel;—and *concinna*, Ait. Hort. Kew. v. 2. 23, miſtaken by Andrews, t. 64, for *abietina*. For this laſt (*concinna*) Mr. Saliſbury has, in our opinion with advantage, adopted the name *paludoſa* from Hermann, which indicates its place of growth, and conſequently its requiſite treatment in a garden.

E. pyramidalis, Ait. Hort. Kew. v. 3. 491. Curt. Mag. t. 366, with two others unknown to us, conſtitute the next ſubdiviſion.

Then follow 12 fine plants, needleſsly, we again preſume, divided into two parcels. Among them are *tubiflora; curviflora; conſpicua*, Ait. Hort. Kew. v. 2. 22. Ait. and Bau. Ic. t. 12; and *ſordida*, Andr. t. 56; with ſeveral often confounded with theſe, (for it is rather an indiſtinct and perhaps variable tribe,) all which contribute much to adorn our green-houſes, and are in general eaſily cultivated.

E. faſcicularis, Linn. Suppl. 219. Ait. and Bau. Ic. t. 6; and *E. Maſſoni*, Linn. Suppl. 221. Curt. Mag. t. 356; occupy a ſection by themſelves. Theſe are two of the moſt highly prized of the whole genus. The flowers of both are tipped with green.

The 12 next are, in general, ſcarcely leſs ſplendid, witneſs *pharetriformis*, Saliſb. (exſurgens, Andr. t. 13.);—*grandiflora*, Linn. Suppl. 223. Curt. Mag. t. 189;—and *longifolia*, remarkable for its tremulous leaves and the variation of colour in its flowers, inſtances of which are diſplayed in Andrews, t. 8, t. 20, and t. 33; likewiſe in Curt. Mag. t. 402. The deep ſcarlet is juſtly the moſt admired variety.—We cannot but think *pinea*, Andr. t. 57, muſt be a diſtinct ſpecies.

To theſe are nearly allied the next five, comprehending *ſeſſiliflora*, Linn. Suppl. 222, (*ſpicata*, Thunb. Diſſ. 43. t. 4. Andr. t. 6);—*alveiflora*, Saliſb. called in the gardens *gelida*, which name aptly expreſſes the cool aſpect of its ſnow-white corolla tipped with pea-green, and ſurely ought to have been retained;—and *mammoſa*, Linn. Mant. 2. 234. Andr. t. 58. (abietina, Schneev. Ic. t. 23.); of which a beautiful ſcarlet variety is moſt common with us, called *ſpecioſa* in Schneevooght, t. 3, and *verticillata* by Andrews, t. 21.

Of Mr. Saliſbury's *brachialis*, a ſolitary ſpecies, we have only ſeen a doubtful ſpecimen.

Four ſpecies follow, among which are *E. Sparmanni*, Linn. Fil. Suppl. 219. Stockh. Tranſ. for 1778. t. 2; and the noble *cerinthoides*, Linn. Sp. Pl. 505. Curt. Mag. t. 220.

E. cernua, Montin Nov. Act. Upſ. v. 2. 292. t. 9. f. 3. Linn. Suppl. 222, ſtands alone; as does Mr. Saliſbury's *doliiformis*, (*mammoſa*, Thunb. Diſſ. de Ericâ, ed. Saliſb. 42. f. 21.)

E. auſtralis, Linn. Mant. 231, not uncommon in gardens;—and *ciliaris*, Linn. Sp. Pl. 503. Curt. Mag. t. 484. follow next. Theſe are both European ſpecies, and are immediately followed by two others, our elegant Engliſh *E. Tetralix*, Curt. Lond. faſc. 1. t. 21. Engl. Bot. t. 1014, (a name changed by Mr. Saliſbury to *botuliformis*, ſauſage-ſhaped);—and his *multicaulis*, the *ſtricta* of Donn and Willdenow, native of Corſica.

Next comes by itſelf our common Britiſh *cinerea*, Curt. Lond. faſc. 1. t. 25. Engl. Bot. t. 1015, more happily, but without any neceſſity, altered to *mutabilus*.

E. regerminans, Linn. Mant. 2. 232, only known in the Linnæan herbarium;—and *pulchella*, Andr. t. 51, occupy two ſeparate ſections.

A very diſtinct and natural aſſemblage of four ſpecies next occurs, in which are *empetrifolia*, Linn. Sp. Pl. 507, known by its hairy corolla;—and *malleolaris*, Saliſb. (*empetrifolia*, Curt. Mag. t. 447.)

The four next ſeem ſcarcely to be ſeparable from them, if we may judge by *viſcaria*, Linn. Mant. 2. 321. Andr. t. 55, the only one of the four with which we are acquainted.

A difficult family of ſeven ſpecies, with a hoary habit, and ſmall turgid downy flowers, is placed next, of which *tardiflora*, Saliſb. (*pubeſcens*, Curt. Mag. t. 480.);—and *hirtiflora*, Curt. Mag. t. 481, are examples. Both are diſtinct from, though nearly allied to, the real *pubeſcens* of Bergius and Linnæus, as well as from his *parviflora*.

A ſomewhat ſimilar tribe, but ſmooth, and with larger more bell-ſhaped flowers, contains ten ſpecies. Amongſt them is *margaritacea*, Ait. Hort. Kew. v. 2. 20. Andr. t. 54, very pretty when laden with its pearly bloſſoms.

E. Bergiana, Linn. Mant. 2. 235, remarkable for its reflexed calyx, with two others, come next, and lead inſenſibly to the following ſection.

This comprehends *pilulifera*, Linn. Sp. Pl. 407;—*obliqua*, Thunb. Diſſ. 44. Ait. and Bau. Ic. t. 3;—and *phyſodes*, Linn. Sp. Pl. 506. Curt. Mag. t. 443; with four more.

E. cernua, Andr. t. 48, ſtands alone, but between it and *phyſodes* we would introduce a new ſpecies, communicated by Mr. G. Hibbert among the reſt of his dried ſpecimens of this genus from the Cape, and by Meſſrs. Lee and Kennedy from their garden, where it firſt bloſſomed in 1808. We would name it

E. roſaria. Leaves in four rows, obtuſe, recurved, toothed. Anthers ſimple, included, with long pores. Corolla ovate, viſcid. The leaves reſemble thoſe of *phyſodes*, but are more diſtant and recurved. Flowers about the ends of the branches, on moſtly axillary, long, viſcid ſtalks, with two or three oblong, pellucid, concave bracteas towards their middle; the flowers droop a little, and are remarkable for their fragrant ſcent, reſembling ottar of roſes. The calyx-leaves are like the bracteas, and about one-third as long as the corolla, which is of a pale ſtraw-colour, ovate, inflated, viſcid, its ſegments obtuſe, crenate, but little ſpreading. Stamens about the length of the calyx; their filaments purple at the ſummit, without any creſt or appendages; anthers brown, oblong, with pores two-thirds of their length. Germen turbinate, furrowed, ſmooth; ſtyle twice as long as the ſtamens; ſtigma capitate, dark coloured.

E. pulchella, Saliſb. a new ſpecies, ſtands alone, the author being unacquainted with its affinity to any other.

Two others, unknown to us, occupy a ſection with *glutinoſa*, Berg. Cap. 98. Ait. and Bau. Ic. t. 17. (*Andromeda droſeroides*, Linn. Mant. 2. 239.) This is a beautiful plant, with all the habit of an *Erica*, nor any thing but an occaſional luxuriance of number in the parts of the flower to make it an *Andromeda*.

A very ſplendid and diſtinct aſſemblage follows, of ſix ſpecies, diſtinguiſhable by their large flowers, with a long tube, always contracted at its mouth, and more or leſs inflated below. The border is ſpreading and ornamental. Among theſe are *retorta*, Linn. Suppl. 220. Curt. Mag. t. 362, firſt found at the Cape by Maſſon, not by Thunberg;—*ampullacea*, Curt. Mag. t. 303;—and *Aitonia*, Curt. Mag. t. 429. This laſt varies a little in the ſize and hue of its border, but ſo ſtrikingly reſembles the Catalonian Jaſmine, that we long ago named it *jaſminea*, nor is there any occaſion for the uncouth preciſion of *jaſminiflora*.—We have ſtill ſome of this tribe, which appear to be nondeſcripts.

Ten ſpecies with flowers of a ſomewhat ſimilar form but ſmaller, and more ſlender needle-ſhaped leaves, conſtitute the next parcel. To this belongs *faſtigiata*, Linn. Mant. 66, of which there are ſeveral elegant varieties, named *E. Humea*, &c. in the gardens. Alſo *E. Muſcari*, Andr. t. 1. ſmelling like the Muſky Hyacinth, which it imitates in colour;—and *comoſa*, Linn. Mant. 234, Ait. and Bau. Ic. t. 18.

A tribe more ſplendid in general, of nine ſpecies, ſucceeds. To theſe belong *inflata*, Thunb. Diſſ. 41. t. 2;—*ventricoſa*, ibid. 27. t. 1. Curt. Mag. t. 350;—*lutea*, Linn. Mant. 234. Andr. t. 11;—*articularis*, Linn. Mant. 65. Curt. Mag. t. 423;—and *taxifolia*, Ait. and Bau. Ic. t. 19.

Two ſpecies, indicated as nearly related to the laſt, cloſe Mr. Saliſbury's liſt of 246 in all. Theſe are *tetragona*, Thunb. Diſſ. 14. t. 4;—and *albens*, Linn. Mant. 231. Curt. Mag. t. 440.

We truſt, that thoſe who may have occaſion to deſcribe new heaths in future, will, as far as they are competent, keep the above arrangement in view, as they will find it very inſtructive, however they may differ from Mr. Saliſbury in principles of nomenclature. To this ſubject we have ſcarcely found it neceſſary to advert, except occaſionally, and we rather paſs over in ſilence what we cannot approve. This botaniſt rejects all names of perſons as applied to the ſpecies of any genus. Mr. Dryander once began a more uſeful reformation in ſuch names of *Ericæ*, making thoſe which commemorate a writer on the ſubject end in *ana*, as *Sebana*; thoſe which apply to a collector only, in the genitive caſe, as *Maſſoni*. The greateſt and moſt correct information is ſtill to be expected from this able botaniſt, in the intended new edition of Mr. Aiton's *Hortus Kewenſis*, where the genus of *Erica* muſt always make a principal figure. S.

Erica, in *Gardening*, comprehends plants of the evergreen, flowery, ſhrubby kind; moſtly exotics; of which the ſpecies moſt in cultivation, according to Martyn, are: the croſs-leaved heath (E. tetralix); the fine-leaved heath (E. cinerea); the double-anthered heath (E. didyma); the tree heath (E. arborea); the Spaniſh heath (E. auſtralis); the many-flowered heath (E. multiflora); the Mediterranean heath (E. Mediterranea); the yellow heath (E. lutea); the purple-ſtalked heath (E. halicacaba); the bladder-flowered heath (E. monſoncana); the mucous heath (E. mucoſa); the hairy-flowered heath (E. urceolaris); the marum-leaved heath (E. marifolia); the bloody-flowered heath (E. cruenta); the ſlender-branched heath (E. rumentacea); the bluſh-flowered heath (E. perſoluta); the three-flowered heath (E. triflora); the arbutus-flowered heath (E. baccans); the ſlender-twigged heath (E. corifolia); the crow berry-leaved heath (E. nipetrifolia); the woolly heath (E. capitata.); the tube-flowered heath (E. lubiflora); the long-tubed yellow heath (E. conſpicua); the honeywort-flowered heath (E. cerinthioides); the tufted-flowered heath (E. comoſa); the tall downy heath (E. Maſſoni); the ſmooth-twigged pencil-flowered heath (E. Plukenetii); the downy twigged pencil-flowered heath (E. Petiveri); the early-flowered dwarf heath (E. herbacea); and the great flowered heath (E. grandiflora). But there are many other ſpecies equally deſerving of cultivation.

Concerning the firſt of theſe ſpecies, it is obſerved by the editor of Miller's dictionary, that it is not inferior to many of the foreign heaths in the beauty and delicacy of its flowers. It is diſtinguiſhed from the other Britiſh heaths not only by the flowers growing in a kind of pendulous cluſter on the tops of the ſtalks, but by the leaves growing in fours, and forming a ſort of croſs.

The whole of the different ſpecies of heaths which are mentioned above, are plants of conſiderable beauty and elegance, but moſtly tender and delicate in their habits of growth.

Method of Culture.—Theſe very elegant plants muſt be treated in different methods, according to their nature and habits of growth.

The firſt three Britiſh ſorts are capable of being propagated by ſowing the ſeeds either in the places where they are to remain, or in pots filled with peaty earth, in either the autumn or ſpring ſeaſons; but this is a tedious method of practice. The better method is, therefore, to take them up from the places where they grow naturally, in the early autumn, with good balls of earth about their roots, planting them again immediately where they are to grow and remain for ornament.

They are found to ſucceed beſt where the ſoil is of the peaty or moory kind, and where it has not been enriched by manure; and as they protrude their roots chiefly near the top, it ſhould be as little dug about them as poſſible, the ſurface only being kept clean and free from rubbiſh.

And the four following ſorts may be increaſed in the ſame manner as the above; but the beſt practice is by layers, cuttings, or ſlips, which ſhould be laid down or planted out in pots filled with boggy earth either in the early ſpring or the latter end of ſummer, plunging them in a moderate hot-bed, and giving them proper ſhade and water. When they have taken full root, they ſhould be carefully removed with balls of earth about them into ſeparate pots, being replaced in the hot-bed till they become well eſtabliſhed, when they will be capable of bearing the open air in mild weather when the ſeaſon is ſuitable.

All the other ſpecies may be increaſed either by cuttings or layers, but moſt of them by the former. The cuttings ſhould be made from the beſt young ſhoots, and be planted in the ſpring ſeaſon in pots filled with a compoſition of light boggy and loamy earth, being placed in the hot-bed, and covered with bell-glaſſes, and duely ſhaded from the ſun, ſlight waterings being given when neceſſary; the layers are beſt laid down in the autumn, being managed in the ſame way as the cuttings. When the plants have become perfectly rooted, they ſhould be removed into ſeparate pots filled with the ſame ſort of mould, being then put in the dry ſtove or green-houſe, where ſome of them require to be conſtantly placed.

But the ninth, twentieth, and twenty-ſixth ſpecies muſt be raiſed by layers, as they have not yet been increaſed by planting their cuttings in the manner directed above.

Where ſeeds are made uſe of in producing theſe plants, they ſhould be ſown in pots filled with the above ſort of earth in the early ſpring, and plunged in the hot-bed of the ſtove. When the plants have acquired a few inches growth, they ſhould be removed into ſingle pots with a little earth about their roots, and be replunged in the hot-bed in the ſtove, being preſerved in it, or the warmeſt part of the green-houſe, during the winter ſeaſon, and whenever the weather is bad.

The firſt three ſorts afford an agreeable variety in the borders and clumps, as they continue long in flower. The four following kinds are likewiſe hardy, and afford variety among other potted plants in the open air during the ſummer months.

All the other ſpecies are more tender, but produce as agreeable an effect among the ſtove and green-houſe collection, from the great beauty and continuance of the flowers in many of the ſorts.

Erica *marina*, *ſea-heath*, a name given by many authors to a very beautiful zoophyte of the fucus kind, called by Mr. Ray and ſome others the fucus ericæ folio.

Erica, in *Ichthyology*, a name given by Gaza and ſome others, as the interpretation of the chalchis of Ariſtotle, that is, as the name of the common herring.

ERICÆ, in *Botany*, the third natural order in the ninth claſs of the ſyſtem of Juſſieu, ſo named from the genus *Erica* which makes a part of it. This order conſiſts of ſuch dicotyledonous monopetalous plants as have perigynous ſtamens, and the following diſtinguiſhing characters. *Calyx* of one leaf, permanent, ſometimes ſuperior, more frequently inferior and deeply divided. *Corolla* of one petal, ſometimes deeply divided, inſerted either into the upper part of the calyx, more commonly into its lower part, or into a gland at its baſe; moſtly withering and permanent. *Stamens* of a definite number, diſtinct, inſerted into the ſame part, or rarely originating from the lower part of the corolla; anthers moſtly with two horns at the baſe. *Germen* ſuperior, or rarely inferior; ſtyle ſolitary; ſtigma generally ſimple. *Fruit* either ſuperior or inferior, with many cells and many ſeeds, either pulpy, or more generally dry with many valves, fixed by their baſes to the central axis, the partitions originating from the middle of each valve. *Seeds* generally minute. *Stem* ſhrubby, of a more or leſs elevation, or herbaceous. *Leaves* alternate, or oppoſite, or whorled.

This order is in a great meaſure analogous to the Linnæan *Bicornes*, excluſive of the *Rhododendra* of Juſſieu, which differ from his *Ericæ* chiefly in having the partitions of the capſule formed of the inflexed margins of its valves, and not originating longitudinally from their centre. Ventenat retains the name of *Bicornes* for the *Ericæ*.

The *Ericæ* are divided by Juſſieu into two ſections, 1. *Germen* ſuperior, conſiſting of *Cyrilla*, Linn. (which being of the ſame genus as *Itea*, and having the capſule of the *Rhododendra*, is to be removed thither); *Blæria*; *Erica*; *Andromeda*; *Arbutus*; *Clethra*; *Pyrola*; *Epigæa* (removed by Ventenat to *Rhododendra*); *Epacris* (omitted by Ventenat); *Gaultheria*; and *Broſſæa* (likewiſe omitted by Ventenat, a very uncertain plant).

2. Germen wholly or partly inferior, *Argophyllum*, Forſt. and Linn. fil.; *Mæſa*, Forſk; and *Vaccinium*.

A third ſection contains two genera allied to *Ericæ*, or ſuppoſed to be ſo, *Empetrum* and *Hudſonia*.

ERICALE, from ηρ, the *ſpring*, and καλη, *beautiful*, a name given by Renealm in his Specimen Hiſt. Plant. 75. t. 68. to the *Gentiana verna*, a moſt elegant vernal plant. Linnæus erroneouſly prints it *Ericoila*.

ERICERUM, a name given by Aetius and other authors to a ſort of collyrium, uſed in weakneſſes of the eyes, in which the herb erica or heath was an ingredient.

ERICEYRA, in *Geography*, a town of Portugal, in the province of Eſtremadura, on the ſea-coaſt; 20 miles N. W. of Liſbon.

ERICHTHONIUS, in *Aſtronomy*, a conſtellation, the ſame as Auriga.

ERICOILA, in *Botany*. See Ericale.

ERICU, a name given in Rheede's Hortus Malabaricus, v. 2. 53. to the *Aſclepias gigantea*. It is corrupted from the Sanſcrit name *Roey*.

ERICUSA, in *Ancient Geography*, one of the ſeven Æolian iſlands, now *Alicuda*.

ERIDANUS, in *Aſtronomy*, a conſtellation of the ſouthern hemiſphere, in form of a river.

The ſtars in the conſtellation Eridanus, in Ptolemy's Catalogue, are 34; in Tycho's, 19; in the Britiſh Catalogue, 84. See Constellation.

Eridanus, in *Ancient Geography*, a river of Italy, in Ciſalpine Gaul, now the Po, which ſee. Virgil deſcribes it as the largeſt river of Italy, calling it the king of rivers:

> "Fluviorum rex Eridanus."

—Alſo, a ſmall river of Greece, in Attica, which purſuing its courſe to the W. of Athens, united with the Iliſſus below that city.—Alſo, a river of Celtica, near the Pyrenées.

ERIE, Fort, in *Geography*, a ſtrong fortification in the townſhip of Bertie, Upper Canada, ſituated on the N. ſhore of lake Erie, at its eaſtern extremity, and the W. bank of Niagara river; 27 miles S. by E. from Niagara fort, 18 above the carrying place of the Falls of Niagara, and 45 from fort Chippeway. This is a ſmall ſtockaded fort, ſomewhat ſimilar to that at Chippeway; and adjoining it are extenſive ſtores as at Chippeway, and about half a dozen miſerable little dwellings. It has a barrack for troops and a block houſe; and a company of ſoldiers is quartered here for the purpoſe of tranſporting the public ſtores. The lake narrows here into the Detroit ſtrait, which carries the waters over the great falls of Niagara. The new fort is projected on a ſmall height in the rear of the preſent garriſon. The harbour is capable of accommodating veſſels of any ſize, which lie oppoſite to the fort, at the diſtance of about 100 yards from the ſhore, expoſed to the violence of the weſterly winds; but the anchorage is good, and they ride in perfect ſafety. The little fort, with the ſurrounding huts built on the rocky ſhore, the veſſels lying off at anchor before it, the rich woods, the diſtant hills on the oppoſite ſide of the lake, and the vaſt lake itſelf, extending to the fartheſt part of the horizon, altogether form an intereſting and beautiful ſcene. N. lat. 42° 53′ 17″. W. long. 78° 20′ 30″.

Erie, *Lake*, called alſo *Eric*, *Erige*, or *Erike*, or the lake of the Cat, is a lake of the fourth magnitude in North America, through which runs the line between the United States and Upper Canada. Detroit river on the weſt brings the waters of the great lakes with which lake Erie has a communication on the north-weſt; and Niagara river on the eaſt forms its communication with the waters of lake Ontario and the river St. Lawrence. It is ſituated between 41° and 43° N. lat. and between 78° 48′ and 83° W. long. It is of an elliptical form, being about 300 miles in length, and about 90, at the wideſt part, in breadth. The depth of water in this lake is not more than 20 fathoms, and in calm weather veſſels may ſecurely ride at anchor in any part of it; but when ſtormy, the anchorage in an open part of the lake is not ſafe, the ſands at the bottom not being firm, and the anchors being apt to loſe their hold. At this time the water becomes turbid, by the waſhing up of the yellow ſand from the bottom of the lake; but in calm weather it is clear, and of a deep greeniſh colour. The northern ſhore of the lake is very rocky, which is alſo the caſe with the ſhores of the iſlands, of which there are ſeveral cluſters towards the weſtern extremity of the lake; but along moſt parts of the ſouthern ſhore there is a fine gravelly beach. The height of the land bordering the lake is very unequal; in ſome places long ranges of ſteep mountains riſe from the very edge of the water; in others, the ſhores are ſo flat and ſo low, that when the lake is raiſed a little above its uſual level, in conſequence of a ſtrong gale of wind ſetting in towards the ſhore, the country is deluged for miles. To the very great inſularity of the height of the land on both ſides of it, is attributed the frequency of ſtorms on this lake; the coaſt, however, on both ſides, is generally favourable for the paſſage of batteaux and canoes. A peninſula, called Longpoint, runs upwards of eighteen miles into the lake, and being compoſed of ſand, is convenient for hauling boats upon it, when the lake is too rough for ſailing and rowing. Towards the ſouth ſide, however, on both ſides of the lake, it would be impoſſible to land, on account of the perpendicular height of the rocks. There is a great deficiency of good harbours along the ſhores of this lake: on its northern ſide there are but two places which afford ſhelter to veſſels drawing more than ſeven feet water, *viz.* Long Point, and Point Abineau, and theſe afford only a partial ſhelter. On the ſouthern ſhore, the firſt harbour you come to in going from fort Erie is that of Preſqu'tele, which is ſituated at the diſtance from that fort of about ſix miles, and where veſſels drawing eight feet water may ride in perfect ſafety. Beyond this, about midway between the eaſtern and weſtern extremities of the lake, there is another harbour, capable of containing ſmall veſſels at the mouth of Cayahega river, and another at the mouth of Sanduſky river, which falls into the lake within the N. W. territory of the States. Britiſh ſhips ſeldom uſe theſe harbours, but trade almoſt ſolely between fort Erie and Detroit river, and in caſe of contrary winds, they return to fort Erie, if bound to Detroit river; or to ſome of the bays amidſt the cluſters of iſlands ſituated towards the weſtern extremity of the lake, if bound to fort Erie. The navigation of this lake is very uncertain; and veſſels are often detained, at a conſiderable expence to paſſengers, in ſome of the harbours. Lakes Huron and Michigan afford communication with lake Erie, by veſſels of eight feet draught. There are portages into the waters of this lake from the Wabaſh, Great Miami, Muſkingam, and Alleghany, from two to ſixteen miles. The iſlands at the weſtern end of the lake, of various ſizes, lie very cloſe to each other, and exhibit a very pleaſing ſcenery; the largeſt of them are not more than fourteen miles in circumference, and many of them are very ſmall. The largeſt iſlands produce a variety of fine timber, amongſt which are found oaks, hiccary trees, and red cedars, which latter, being large, are ſent for even from the Britiſh ſettlements on Detroit river, at the diſtance of forty miles. Lake Erie has a great variety of fine fiſh, ſuch as ſturgeon, eel, white fiſh, trout, perch, &c. Amongſt the woods are found racoons and ſquirrels, and alſo bears, in the winter ſeaſon, when the lake is frozen between the main land and the iſlands. All the iſlands are dreadfully infeſted with ſerpents, and on ſome of them rattleſnakes are ſo numerous, that in the height of ſummer it is dangerous to land. Two kinds of rattleſnakes are found in this part of the country; the one is of a deep brown colour, clouded with yellow, about thirty inches in length, which frequents marſhes and low meadows, and does great miſchief among cattle: the other ſort is of a greeniſh yellow colour, clouded with brown, and nearly twice the ſize of the former. Many different kinds of ſerpents, beſides rattleſnakes, are found on the iſlands in lake Erie. The ponds and marſhes in the interior parts of theſe iſlands abound with ducks and other wild fowl, and the ſhores ſwarm with gulls; among the woods are a few ſmall birds, remarkable neither for their ſong nor plumage. Weld's Travels, vol. ii.

Erie, a county of Pennſylvania, on the ſouth ſide of lake Erie, containing 639,400 acres, and 1468 inhabitants. Its chief town is Erie.

ERIEUX, a river of France, which runs into the Rhone, at Beauchaſtal.

ERIFFS, a name given to canary birds when about two years old. See Canary *Bird.*

ERIGENA, John Scotus, in *Biography*, who flouriſhed in the ninth century, was probably born in Ayrſhire Scotland, though ſome writers make him a native of Herefordſhire, in England, and others ſuppoſe his birth-place to be Ireland. He poſſeſſed an ardent thirſt for literature, and ſpared no pains in rendering himſelf accompliſhed in the learning of the Eaſt, and from the extent of his erudition he obtained the name of "Scotus the Wiſe." He ſtudied ſome years at Athens, and became very converſant in Greek philoſophy. Upon his return, he accepted an invitation from Charles the Bald of France, and lived for ſeveral years in habits of intimacy and familiarity with his royal patron, who aſſigned to him the direction of the univerſity of Paris. To the ſovereign he was not only an inſtructor in literature and ſcience, but an adviſer in the affairs of government. The high rank which he obtained excited much jealouſy, particularly among the bigotted prieſts, who accuſed him of maintaining heretical opinions. In the year 824, the Greek emperor, Michael the Stammerer, ſent to the Weſtern emperor, Lewis the Pious, a copy of the treatiſes of the ſuppoſed Dionyſius the Areopagite, which had long been held in great veneration among the Greek Chriſtians. Dionyſius was ſuppoſed to be the firſt Chriſtian teacher in France, and, on that account, the work in queſtion was deemed of great value, and the king, who was unable to read the original Greek, employed Erigena to tranſlate it into the Latin language. Unfortunately this was performed without licence from the pope, who, when he found the tranſlation eagerly read, inſiſted that the French king ſhould not only baniſh Erigena from Paris, but ſhould ſend him to Rome. Charles refuſed to act in this ungenerous manner, nevertheleſs, it was deemed adviſable, that Erigena ſhould leave the capital of France, and in a ſhort time after he took refuge in England. This tranſlation of Dionyſius's treatiſes is ſaid to have cauſed the revival of the knowledge of the Alexandrian Platoniſm in the Weſt, and to have laid the foundation of the myſtical ſyſtem of theology which afterwards ſo generally prevailed. Of the original works of Erigena, the principal was his treatiſe "On the Diviſion of Nature, or the Nature of Things," which was publiſhed from the author's MS. by Dr. Thomas Gale, at Oxford, in 1681, under the title of "Joannis Scoti Erigena de Diviſione Naturæ, Libri quinque, diu deſiderati." Erigena was employed by our great king Alfred in the reſtoration of learning at Oxford, where he was appointed profeſſor of mathematics and aſtronomy. In this ſituation he remained only about three years, when ſome differences that took place in the univerſity obliged him to retire to the abbey of Malmſbury in Wiltſhire, where he opened a ſchool. Here, it is aſſerted, by moſt writers, that he was murdered by his own ſcholars, either on account of his harſhneſs and undue ſeverity; or at the inſtigation of the monks, who hated Erigena as being a heretic, and much more learned than themſelves. The particular time and place of his death have been the ſubjects of ſome diſpute. Certain writers contend that his death took place about the year 864 or 866, and others, who are generally followed, make it in 883. Some ſay he died in England, and others, among whom is Dr. Henry, think that it happened in France. He was certainly a very extraordinary man for the times in which he lived, and after his deceaſe his name was, for a conſiderable time, to be found in the liſt of the ſaints of the Romiſh church, till it was ſtruck out of the calendar, by Baronius, on account of the heterodoxy of his opinions concerning tranſubſtantiation. Biog. Brit. Enfield's Hiſt. Phil.

ERIGENS Penis. See Erector.

ERIGERON, in *Botany*, ηριγερων of the ancient Greeks, from ηρ, *the ſpring*, and γερων, *an old man*, becauſe it is hoary in the ſpring. Linn. Gen. 422. Schreb. 553. Willd. Sp. Pl.

Pl. v. 3, 1952. Sm. Fl. Brit. 876. Mart. Mill. Dict. v. 2. Juſſ. 180. Gærtn. t. 170. Claſs and order, *Syngeneſia Polygamia-ſuperflua*. Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* oblong, cylindrical, imbricated; ſcales awl-ſhaped, erect, gradually longer, nearly equal in breadth. *Cor.* compound, radiated; *florets* of the diſk all perfect, tubular, funnel-ſhaped, with an equal five-cleft limb; thoſe of the radius female, ligulate, linear, awl-ſhaped, erect, for the moſt part entire. *Stam.* (in the tubular florets) Filaments five, capillary, very ſhort; anthers forming a cylindrical tube. *Piſt.* (in the tubular florets) Germen minute, crowned with hairs longer than its own corolla; ſtyle thread-ſhaped, the length of the hairs; ſtigmas two, oblong, revolute: the female or ligulate florets differ in having their corolla about as long as the hairs, and very ſlender ſtigmas. *Peric.* none, except the cloſed permanent calyx. *Seeds*, in the florets of the diſk as well as of the radius oblong, ſmall. *Down* long, capillary. *Recept.* naked, flat.

Obſ. Dillenius obſerves that the innermoſt or central florets of the diſk are generally males. One ſpecies has thoſe of the radius deſtitute of a corolla.

Eſſ. Ch. Receptacle naked. Down ſimple. Florets of the radius linear, very narrow, numerous. Calyx imbricated.

This genus comprehends ſeveral plants called *Conyza*, *Virga-aurea*, *Aſter*, and *Senecio* by former writers, but is a very natural one, characterized by the erect very narrow florets of its radius, uſually coloured blue or white. The lateſt edition of Linnæus has 22 ſpecies, Willdenow 32. Three are natives of Britain.

1 E. *canadenſe*, Engl. Bot. t. 2019. "Stem hairy, panicled. Leaves lanceolate; the lower ones toothed."—To all appearance perfectly wild in Glamorganſhire, (Mr. Middleton), though ſuppoſed by Ray to have come over from North America, where it abounds. It is an annual plant, of mean appearance, with innumerable ſmall flowers, whoſe radius is white or pale red, their diſk yellow.

2. E. *acre*. Engl. Bot. t. 1158. Curt. Lond. faſc. 1. t. 60. "Stem racemoſe. Stalks moſtly ſingle-flowered. Leaves lanceolate or tongue-ſhaped, ſeſſile."—Common on a dry gravelly or chalky ſoil, flowering in July and Auguſt. The flowers are larger and fewer than in the former; their radius blue. Root biennial.

3. E. *alpinum*. Engl. Bot. t. 464. "Stems almoſt ſingle-flowered. Calyx ſlightly hairy. Radius ſpreading."—Found in moiſt parts of the highland mountains of Scotland, flowering in July. This has ſeldom more than one flower on a ſtem, which is much larger than in E. *acre*, with a longiſh blue radius, which ſpreads more than is conſiſtent with the generic character, and, perhaps, might authorize the removal of this ſpecies to *Aſter*, where Linnæus originally placed its near ally E. *uniflorum*, Fl. Lapp. n. 307. t. 9. f. 3.

ERIGONUS, in *Ancient Geography*, a river of Macedonia, which, according to Livy, ran from Illyria through Pæonia into the Axius; called *Erigon* by Strabo and Ptolemy.

ERINACEA, in *Botany*, Tourn. Inſt. 646, ſee ANTHYLLIS, ſp. 15. Tournefort eſtabliſhed it as a genus, (diſtinct from his *Geniſta-Spartium*, which conſiſts of *Ulex* and the prickly *Geniſtæ*,) merely becauſe the buſh is all over armed with prominent ſtrong ſpines, like a hedge-hog.

ERINACEUS, a name given by Dillenius and Micheli to a genus of *Fungi*. Linnæus, perceiving the inconvenience and abſurdity of adopting a generic denomination, already univerſally appropriated to an animal, changed it to *Hydnum*.

ERINACEUS, in *Zoology*, a genus of the Feræ order, the hedge-hog of Engliſh authors. This tribe is diſtinguiſhed principally by the teeth. The fore-teeth in the upper jaw are two, and diſtant, in the lower two approximate; the tuſks in the upper jaw five each ſide, in the lower three; grinders four each ſide above and beneath; body above covered with ſpines.

Species.

EUROPÆUS. Ears rounded; noſtrils creſted. Linn. Fn. Suec. *Erinaceus auriculis erectis*, Briſſ. *Echinus terreſtris*, Geſn. *Igel*, Knorr. *Heriſſon*, Buff. *Common hedge-hog*.

The common hedge-hog, or as it is ſometimes called erroneouſly the European hedge-hog, appears to be a native of the temperate parts of Aſia, and to be found in Madagaſcar as well as Europe. It lives in thickets and buſhes, forming a neſt of moſs, graſs, or leaves, of large ſize. When diſturbed it rolls itſelf up into a globular form, preſenting on every part a formidable armament of ſpines, and this is indeed its principal means of defence; upon being immerſed in cold water it expands, and ſwims with perfect facility. During the winter it is ſuppoſed to remain in a ſtate of torpidity.

Vegetables of various kinds, as the roots of plants, or fruits, reptiles, ſmall birds and inſects, conſtitute the principal food of this animal; the Calmucs tame and keep it in their dwellings like the cat; and in this reſpect they become uſeful, as they deſtroy the cockroaches, and other obnoxious inſects. They produce from three to five young at a birth. The fleſh is very indifferent, yet is ſpoken of among the old writers as an article of food, with inſtructions for roaſting or otherwiſe preparing it for the table.

The hedge hog is conſidered as an inoffenſive animal, notwithſtanding the vulgar ſuppoſition, that it ſucks the teats of cattle by night, and occaſions ulcerations in thoſe tender parts with the irritation of their prickles. The animal has a muſky ſmell. Length ten inches.

INAURIS. Without external ears. Linn. Seba. *Gaiana hedge-hog*.

Length eight inches. Inhabits South America. The head is thick, ſhort; ſpines cinereous tinged with yellow; hair ſoft, whitiſh cheſnut over the eyes; tail ſhort; claws long and crooked. Deſcribed on the authority of Seba.

AURITUS. Ears oval, long. *Auriculis ovalibus longis, naribus criſtatus*, Pallas. Nov. C. Pet. *Siberian hedge-hog*.

Inhabits the lower parts of the Volga and Ural and extends from thence to the eaſtern parts beyond the lake Baikal. Its form reſembles that of the common hedge-hog, but is ſmaller, the eyes larger, wiſkers diſpoſed in four rows; the feet longer, more ſlender; tail ſhorter, conic, annulated, and nearly bald. The female is ſaid to breed twice a year, and to produce from four to ſeven each time.

MALACCENSIS. Ears pendulous. Briſſ. *Hyſtrix brachyura*, Linn. *Porcus aculeatus, ſ. Hyſtrix malaccenſis*, Seba. *Malacca hedge-hog*.

Extremely allied in its general appearance to the porcupine, and referred to the hedge-hog tribe chiefly on account of the number and arrangement of the teeth. Its ſize is ſuppoſed to be equal to that of the common porcupine. This animal is ſaid to inhabit Aſia, and to produce the precious ſtone called Piedra del Porco, the imaginary virtues of which are ſo highly extolled in the old materia medica.

SETOSUS. Ears ſhorter; top and hind head and ſhoulders beſet with ſpines; tail very ſhort and ſpinous. *Erina-*

ceus ſetoſus, Gmel. Schreber. *Tendrac*, Buff. *Petit tendrac de Madagaſcar.* Sonner. *Aſiatic hedge-hog.*

Native of India and Madagaſcar; length ſix inches; wallows in the mire, and grunts like a hog, and forms burrows. Remains torpid for ſix months, during which the hair falls off.

Ecaudatus. No tail; ſnout very long and acute. Schreber. *Tanrec, et le jeune tanrec*, Buff. *Madagaſcar hedge-hog.*

Inhabits India and Madagaſcar. In habit reſembles the former, but is larger, meaſuring in length eight inches. The mouth and eyes are ſmall; ears rounded and longer than in the ſetoſus; the ſpines black, and covering the whole back and ſides; hair yellowiſh and feet tawny.

The two laſt mentioned animals are conſidered by Pennant as the ſame ſpecies, on the preſumption that the former is the adult ſtate, the other in a leſs advanced ſtage of growth. Dr. Shaw ſeems inclined to adopt this ſuppoſition. There, nevertheleſs, appears in our mind no plauſible reaſon for ſuch conjecture, unleſs the deſcriptions be defective in the moſt eſſential particular; for, if one has a tail and the other none, they muſt be diſtinct. That the animal deſcribed by Buffon had not obtained its full growth is rendered extremely probable by the explanation afforded, but the production of a tail cannot be ſuppoſed to depend on the age of the animal. The tanrec feeds on fruits, and remains torpid during about three months of the year.

ERINÆI, in *Ancient Geography*, a people of Aſiatic Sarmatia. Ptolemy.

ERINDES, a river of Aſia, towards Hyrcania or Sparta, according to Tacitus.

ERINEUS, one of the four cities of Doris, ſituate on the moſt northern verge of the kingdom, near the foot of the hills which part Doris from Macedonia.—Alſo, a port of the ſea of the Peloponneſus, in Achaia, between Ægium and the promontory Rhium. Pliny.—Alſo, a river of Sicily, according to Thucydides, called *Orinos* by Ptolemy.

ERINGO. See Eryngo.

ERINNA, in *Biography*, a Greek poeteſs, mentioned by different writers as a native of Leſbos, of Teios, of Rhodes, and of Tenos in Laconia, is ſuppoſed to have been contemporary with Sappho, about the year 600 B.C. but ſhe is placed by the Chronicle of Euſebius 250 years later. She was celebrated in ancient Greece, and ſeveral epigrams were written upon her, one of which ſpeaks of her as inferior to Sappho in lyrics, and ſuperior in hexameters. Some fragments are extant in her name, which are inſerted in the "Carmina Novem Poetarum Fœminarum." Antw. 1568. Voſſ. Poet. Græc.

ERINUS, in *Botany*, a name adopted by Linnæus from Dioſcorides, the etymology of which is unknown. Neither is his ερινος the ſame with the Linnæan plant, but rather, we preſume to think, ſomething which has hitherto eluded the ſagacity of commentators. His deſcription accords in ſome points with *Samolus Valerandi*.—Linn. Gen. 318. Schreb. 4 7. Willd. Sp. Pl. v. 3. 332. Mart. Mill. Dict. v. 2. Juſſ. 100. Gærtn. t. 55.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Pediculares*, Juſſ.

Gen. Ch. *Cal.* Perianth in five deep, lanceolate, erect, nearly equal, permanent ſegments. *Cor.* of one petal, unequal; tube cylindrical, ſomewhat ovate, the length of the calyx, reflexed; limb flat, in five deep, nearly equal, inverſely heart-ſhaped ſegments. *Stam.* Filaments four, very ſhort, within the tube of the corolla; two of them (the uppermoſt) a little longer than the others: anthers ſmall. *Piſt.* Germen nearly ovate; ſtyle very ſhort; ſtigma capitate. *Peric.* Capſule ovate, inveſted with the calyx, of two cells and two valves, the latter cloven half way down when ripe; partition double. *Seeds* numerous, ſmall. *Recept.* compreſſed.

Eſſ. Ch. Calyx of five leaves. Limb of the corolla in five, nearly equal, notched ſegments. Capſule of two cells. Seeds numerous.

Obſ. By an unaccountable error in the Eſſ. Char. in all the editions of Linnæus the upper lip is ſaid to be very ſhort and reflexed, though the whole limb of the corolla is juſtly deſcribed as (nearly) equally five-cleft. Willdenow copies this, though the Hortus Kewenſis had corrected it.

E. *alpinus* is the beſt-known ſpecies. "Flowers racemoſe. Leaves ſpatulate."—Linn. Sp. Pl. 878. Curt. Mag. t. 310. Native of the alps of Switzerland, and the Pyrenæan mountains, flowering in the middle of ſummer. It forms tufts, with ſeveral dwarf ſtems, bearing numerous purple flowers, and is a very ornamental plant for rock-work, requiring protection againſt ſevere froſt and exceſſive moiſture, like moſt alpine rock plants. It is increaſed by parting the roots, or by ſeed.

E. *africanus*. "Flowers axillary, ſeſſile. Leaves lanceolate, ſlightly toothed."—Linn. Sp. Pl. 878. (Lychnidea villoſa, foliis ex alis floriferis, &c.; Burm. Afr. t. 50. f. 1.) Native of the Cape of Good Hope. This has a taller, more branched ſtem, more oblong leaves, and axillary flowers, of what colour we know not, with a very long ſlender curved tube. It has not yet appeared in our gardens.

E. capenſis. "Flowers ſpiked. Leaves linear, toothed."—Linn. Mant. 252, excluding Burman's ſynonym. Gathered by Sparmann in ſandy ground at the Cape of Good Hope. This is alſo a ſtranger to our gardens. The flowers are ſaid to be yellow and very fragrant. In the dried plant they are black. The tube is an inch and half long; the ſegments of the limb deeply cloven, the lobes dilated, obtuſe and divaricated.

E. *fragrans*. "Leaves lanceolate-oblong, toothed. Segments of the limb undivided."—Ait. H. Kew. v. 2. 357. (Selago Lychnidea; Linn. Sp. Pl. 877. Lychnidea villoſa, foliis oblongis, &c. Burm. Afr. t. 49. f. 4.) Native of the Cape, rarely ſeen in our green-houſes. The flowers are yellow or browniſh, and fragrant.

E. *triſtis*. "Leaves oblong, cut, toothed. Segments of the limb ſlightly cloven."—Linn Suppl. 287.—Found by Thunberg at the Cape. The flowers are ſaid to be ſweet-ſcented, and of a dull colour.

E. *peruvianus* and *laciniatus* of Linnæus, are both nearly related to *Verbena Aubletia*, and the former at leaſt ſeems to be the very ſame ſpecies.

ERIOCALIA, from εριον, *wool*, and καλια, *a neſt*, in alluſion to the ſingularly woolly involucrum in the midſt of which the flowers are ſeated as in a bird's neſt. Sm. Exot. Bot. v. 2. 37. Intr. to Bot. 373. (Actinotus; Labillard. Nov. Holl. 67.) Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*.

Gen. Ch. *Umbel* ſimple, of many ſhort rays. *Invol.* of many lanceolate, equal, undivided, coloured leaves, longer than the rays of the umbel, and denſely clothed with wool. *Cal.* Perianth ſuperior, in five deep, equal, concave, ſometimes coloured, externally hairy, permanent leaves. *Cor.* none. *Stam.* Filaments five, about as long as the calyx, equal, awl-ſhaped; anthers roundiſh, of two lobes. *Piſt.* Germen inferior, obovate, compreſſed, furrowed, very hairy; ſtyles two, capillary, ſpreading, longer than the ſtamens; ſtigmas ſimple. *Peric.* Fruit ovate, obtuſe, compreſſed, furrowed, hairy, crowned with the calyx and ſtyles. *Seed* ſolitary?

Eſſ. Ch. Umbel ſimple. Involucrum of many lanceolate,

late, equal, woolly, coloured leaves, longer than the umbel. Fruit compreſſed, hairy. Petals none. Many flowers abortive.

This New Holland genus bears the moſt ſtriking analogy to the European *Aſtrantia*, from which it differs in its woolly, not ſmooth, involucrum, but more eſſentially in having no petals, and in its hairy, not muricated, fruit. M. Labillardiere had, unknown to us, previouſly named it *Actinotus*, but that name being already long ago occupied in mineralogy, is untenable in botany.

The only ſpecies known are two.

1. E. *major*. Sm. Exot. Bot. v. 2. 37. t. 78. (Actinotus helianthi; Labill. Nov. Holl. 67. t. 92.) "Segments of the leaves bluntiſh, flat, woolly on both ſides. Flower-ſtalks ſomewhat corymboſe."—Native of the ſandy country about Port Jackſon, New South Wales, as well as of the weſt coaſt of New Holland, flowering in October. The *root* appears to be annual; it is woody and branching. *Stem* ſolitary, about two feet high, erect, leafy, round, woolly, but little branched except at the upper part, where the long flower-ſtalks, more or leſs numerous, grow in a corymboſe form. *Leaves* alternate, ſtalked, three-cleft, lobed and pinnatifid; their ſegments ſpreading, linear, entire, flat, a little dilated upward, and bluntiſh; clothed with denſe wool, whiter beneath. *Stipulas* none. *Flowers* terminal, large and ornamental, all over white with a green or rufous tinge. *Involucrum* of eight or ten ſpreading leaves, each an inch or more in length, peculiarly ſoft and pliable, like velvet. *Flowers* very numerous, forming a convex compact ſort of diſk, thoſe of the circumference males. *Calyx* whitiſh, ſo as to reſemble petals. No aromatic or pungent flavour is perceptible in any part of the plant.

2. *E. minor*. Sm. Exot. Bot. v. 2. 39. t. 79. "Segments of the leaves acute, revolute; ſmoothiſh above; ſilky beneath. Flower-ſtalks ſcattered."—Found near Port Jackſon, in a ſandy or gravelly ſoil, flowering in March.—Much ſmaller than the laſt, and bearing the ſame analogy to it that *Aſtrantia minor*, Sm. Exot. Bot. t. 77, does to the *major*, t. 76.—*Root* woody, branched, perhaps perennial. *Stem* a foot or two high, much branched, leafy, round, clothed with cloſe-preſſed hairs. *Leaves* on long foot-ſtalks, divided into three or five deep, ſpreading, dilated, acute, revolute, pinnatifid or three-cleft lobes; green, ſmooth, or ſlightly hairy, above; denſely clothed with white ſilky hairs beneath. *Flowers* on long, ſolitary, terminal, naked ſtalks, ſcarcely a quarter ſo large as in the other. *Calyx* green, and not coloured. *Involucrum* almoſt naked underneath; hairy, ſomewhat ſilky, white or reddiſh above. This ſpecies is likewiſe without any peculiar flavour.

ERIOCAULON, from εριον, *wool*, and καυλος, *a ſtem*, becauſe of the woolly or hairy ſtalk, which however is rarely the caſe. Linn. Gen. 40. Schreb. 56. Willd. Sp. Pl. v. 1. 485. Sm. Fl. Brit. 1009. Juſſ. 44. Gærtn. t. 83.—Claſs and order, *Monoecia Triandria*, Smith. (*Triandria Trigynia*, Linn.) Nat. Ord. *Junci*, Juſſ.

Gen. Ch. *Common calyx* globoſe, depreſſed, imbricated, many-flowered; its ſcales lanceolate or obovate, obtuſe, ſcarioſe, equal, permanent; perianth inferior, of two or three obtuſe, permanent, muricated leaves. *Male flowers* ſeveral, in the middle of the diſk. *Cor.* funnel-ſhaped; tube about as long as the calyx; limb in two deep, obtuſe, muricated lobes. *Stam.* Filaments three or four, equal, inſerted into the tube of the corolla, and rather longer than the limb; anthers vertical, roundiſh, of two lobes. *Piſt.* Germen obſolete; ſtyle capillary, cloven; ſtigmas blunt. *Female flowers* ſeveral, in the circumference, between the calyx-ſcales. *Cor.* inferior, of two oblong, concave, obtuſe petals, muricated at the upper part externally. *Stam.* none. *Piſt.* Germen ſuperior, of two or three lobes; ſtyle thread-ſhaped, ſhorter than the corolla, cloven; ſtigmas two or three, acute. *Peric.* Capſule roundiſh, of two or three lobes, with as many cells and valves. *Seeds* ſolitary.

Eſſ. Ch. Common calyx of many leaves, many-flowered; perianth ſuperior, of two or three leaves. Male flowers central. Corolla of one petal, cloven. Female fl. in the margin. Corolla of two petals. Stigmas two or three. Capſule of two or three cells. Seeds ſolitary.

The characters of this genus were ſo ill defined in the works of Linnæus, that Hudſon conceived our Britiſh *Eriocaulon*, confounded by Linnæus with his *decangulare*, muſt be a diſtinct genus, and he therefore called it *Naſmythia*, in honour of ſir James Naſmyth, baronet; ſee Fl. Angl. ed. 2. 414. As however no genus can be more natural and diſtinct than *Eriocaulon*, and the fault appears to have been entirely in the deſcriptions of authors, its characters are now reformed. The above deſcription is made from the only Britiſh ſpecies, *E. ſeptangulare*, With. 184. Sm. Fl. Brit. 1010. Engl. Bot. t. 733.—"Stalk with ſeven angles. Leaves ſharp-pointed, with an internal network of cells. Male flowers with four ſtamens." It grows in ſeveral lakes in the iſle of Skye very abundantly, and was found in September 1801 by Dr. Wade, decorating the edges of all the lakes in Cunnamara, in the county of Galway, Ireland. The *root* is perennial, conſiſting of abundance of ſimple, white, ſhining fibres, compoſed internally of a ſeries of cells, frequently interrupted by tranſverſe partitions, which is the general ſtructure of the whole herb. *Stalk* a ſpan high, ſolitary, upright, ſimple, naked, twiſted, with ſeven angles and as many intermediate furrows, ſmooth, (ſo that in this inſtance the generic name does not well apply), inveſted with a tubular ſheath at the baſe. *Leaves* numerous, radical, ſword-ſhaped, ſmooth, taper-pointed, about two inches long. *Head* of flowers terminal, ſolitary, hemiſpherical, about three lines broad, prettily variegated with dark purple and white, the calyx and anthers being of the former colour, as well as a few ſpots on the white corolla. The ſnow-white club-ſhaped protuberances, with which the extreme parts of the calyx and corolla are muricated, give the whole an elegant feathery aſpect.

Linnæus knew about five ſpecies of *Eriocaulon*, but very imperfectly, and he was cautious of adopting Dr. Hope's accurate generic deſcription of the above plant, publiſhed in the Philoſophical Tranſactions, v. 59. 243. t. 12, leſt it ſhould not accord with every ſpecies. As far as ſubſequent examination of the ſeveral exotic ones has gone, it is found to confirm the account here given. Willdenow enumerates eight ſpecies in all; Lamarck deſcribes 12 in his Encyclopedie, v. 3. 274—277, and figures 4, rather imperfectly, in his t. 50. This laſt author is, nevertheleſs, the beſt we have on the ſubject, though Willdenow heſitated to follow him, and Vahl, in his Sp. Pl. v. 2. 210, removes his *E. ſpadiceum*, perhaps rightly enough, to *Schoenus*.

Authors are very much confuſed in their accounts of the native countries of ſeveral ſpecies. The *repens* of Lamarck was gathered by Thierry de Menonville in Hiſpaniola, not by Commerſon in the iſle de Bourbon. *E. ſpadiceum* of the ſame author was found by Smeathman at Sierra Leone, from whom we have it in plenty, and whom Lamarck rightly quotes; yet Vahl mentions St. Domingo (Hiſpaniola) a its native country, on the authority of Lamarck's herbarium, without naming Smeathman.

The following 6 ſpecies we believe are hitherto entirely nondeſcript. They will probably appear, with others, more fully illuſtrated hereafter from the pen of Mr. R.

Brown, when he has time to reſume the ſtudy of this genus, of which we believe he has aſcertained about 30 ſpecies. In the mean while, to ſecure his ſpecific names and our own thus far, we ſhall attempt definitions of what we have determined from actual obſervation.

E. *pygmæum*, Soland. MSS.—Stalks aggregate, five-angled. Leaves and ſheaths rough; the latter longeſt. Head globoſe. Calyx-ſcales obovate, pointed.—Native of New Holland. *Herb. Linn. fil.* The *ſtalks* are about two inches high. *Leaves* about half an inch long, being rather ſhorter than the ſheaths of the ſtalks, which is unuſual. *Heads* browniſh.

E. *ſcarioſum*.—Stalks aggregate, five-angled. Leaves and ſheaths ſmooth, of equal length. Head globoſe. Calyx-ſcales obovate, acute.—Communicated from New South Wales in 1792, by John White, M. D.—*Stalks* five or ſix inches high. *Heads* of a ſilvery white, ſcarcely ſo large as a pea, being about twice as big as the former.

E. *ſtupeum*.—Stalk nearly ſolitary, five-angled. Leaves and ſheaths of equal length, denſely woolly at the baſe. Head hemiſpherical. Calyx-ſcales obovate, acute. Gathered by Sonnerat at the Iſle de Bourbon. *Stalk* ſometimes above a ſpan high. *Leaves* ſpreading, involute when dry, ſmooth, or nearly ſo, but enveloped at their baſe, as well as the ſheath of the ſtalk, by a denſe integument of ſilky wool. *Head* much like that of *E. ſeptangulare*.

E. *latifolium*.—Stalks ſomewhat aggregate, cylindrical, furrowed. Leaves ſmooth, taller than the ſtems. Head hemiſpherical. Outer calyx-ſcales rounded, obtuſe; inner lanceolate, acute.—Gathered at Sierra Leone by Dr. Afzelius. The very long and broad flat *leaves*, a ſpan in length, are remarkable. The *ſheaths* are alſo large, about half as long as the ſtalk. *Head* ſmaller than in the laſt, variegated with brown and white.

E. *fiſtuloſum*. Brown MSS.—Stalks aggregate, cylindrical, ſtriated. Leaves ſmooth, twice as long as the ſheaths. Head hemiſpherical. Inner calyx-ſcales obovate, pointed.—Native of New Holland.—*Stalks* a ſpan high. *Leaves* about half as long, or more, taper-pointed, ſmooth, rather turgid. *Heads* ſmall, browniſh.

E. *depreſſum*. Brown MSS.—Stalks aggregate, cylindrical, furrowed. Leaves ſmooth, as tall as the ſtalks. Head flattened. Calyx-ſcales wedge-ſhaped, obtuſe. Native of New Holland. *Stalks* about two inches high. *Heads* hemiſpherical beneath, nearly flat at the top, dark purpliſh brown.

We have in our deſcriptions ſubſtituted the word ſtalk (*ſcapus* or *pedunculus*) for ſtem, as being more correct. S.

ERIOCEPHALUS, ſo named by Dillenius from εριον, *wool*, and κεφαλη, *the head*, in alluſion to the remarkably woolly appearance, ſingular in the tribe to which it belongs, which this plant makes when in ſeed. Linn. Gen. 450. Schreb. 586. Willd. Sp. Pl. v. 3. 2384. Mart. Mill. Dict. v. 2. Juſſ. 186. Gærtn. t. 168.—Claſs and order, *Syngeneſia Polygamia-neceſſaria*. Nat. Ord. *Compoſitæ nucamentaceæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* erect, of ten ovate, equal, cohering ſcales; the five outermoſt keeled, the inner ones flat. *Cor.* compound, radiated; the perfect florets doubly numerous, conſtituting the diſk; female ones five, making the radius: that of the perfect florets funnel-ſhaped, with a five-cleft ſpreading border; of the radius flat, inverſely heart-ſhaped, with three terminal lobes. *Stam.* in the perfect florets, Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* in the perfect florets, Germen obſolete; ſtyle ſimple; ſtigma cloven, acute: in the female ones, Germen ovate, naked; ſtyle ſimple; ſtigma pointed, inflexed. *Peric.* none, except the ſcarcely altered calyx. *Seeds* in the diſk none; in the radius obovate, naked. *Recept.* flat, woolly, and the elongated wool which ſeparates the two rows of calyx-ſcales, is moreover introduced between the perfect and female florets.

Obſ. A ſmall compreſſed body adheres to the baſe of each ſcale of the calyx.

Eſſ. Ch. Receptacle woolly. Seed-down none. Calyx of ten equal leaves. Florets of the radius five, inverſely heart-ſhaped.

The ſpecies are two, both ſhrubs natives of the Cape of Good Hope, and to be met with, though rarely, in our green-houſes.

1. E. *africanus*. Linn. Sp. Pl. 1310. Ait. Hort. Kew. v. 3. 278. Curt. Mag. t. 833. (E. ſempervirens, foliis faſciculatis & digitatis; Dill. Elth. v. 1. 132. t. 110. f. 134.) "Leaves lobed or undivided. Flowers corymboſe."—The *leaves* are faſciculated, fleſhy, and nearly cylindrical, hoary and glaucous, moſtly undivided, ſometimes with two or three lobes or notches. *Flowers* reſembling many ſpecies of Yarrow, *Achillea*, having broad white radiant florets, and a ſmall purple and yellow diſk. The *ſeeds* are enveloped in the long ſoft hairs of the receptacle which come forth after the flowering is paſt. It is propagated by cuttings, and flowers from January to March.

2. E. *racemoſus*. Linn. Sp. Pl. 1311. Ait. Hort. Kew. v. 3. 279.—"Leaves linear, flat, undivided. Flowers racemoſe."—The *leaves* are ſhorter, flatter, and leſs faſciculated than in the former. *Flowers* in long cluſters or rather ſpikes. *Wool* of the receptacle very long.—Dr. Sims in Curt. Mag. juſtly refers Gærtner's ſynonym to the foregoing ſpecies, not to this.

ERIOGONUM, from εριον, *wool*, and γονυ, *a joint*, in alluſion to the woollineſs of the habit, and the jointed ſtructure of the ſtem. Michaux Fl. Boreali-Amer. v. 1. 246. Claſs and order, *Enneandria Trigynia*. Nat. Ord. *Holoraceæ*, Linn. *Polygoneæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in ſix deep, obovate, coloured, ſpreading ſegments, of which the three innermoſt are ſomewhat the largeſt. *Cor.* none. *Stam.* Filaments nine, occaſionally eight or ten, rather longer than the calyx and inſerted into its baſe, hairy in their lower part; anthers roundiſh, verſatile, incumbent. *Piſt.* Germen ſuperior, oblong, triangular, with three furrows; ſtyles three, the length of the ſtamens; ſtigmas ſimple, obtuſe. *Peric.* Capſule triangular, membranous, not burſting. *Seed* ſolitary, triangular, ſharp at each end, black; with a ſnow-white, ſmall, farinaceous albumen, and large flat cotyledons.

Eſſ. Ch. Calyx inferior, coloured, in ſix deep ſegments, permanent. Capſule membranous. Seed ſolitary, triangular. Stigmas ſimple.

This genus in its parts of fructification very nearly approaches *Polygonum*, but the above characters are ſufficient to diſtinguiſh it, and the habit, more eſpecially the abſence of ſtipulas, renders it totally diſtinct. We are poſſeſſed of three ſpecies, one of which only has been hitherto mentioned.

1. E. *tomentoſum*. Michaux as above, t. 24. (Chryſoſplenium? oppoſitifolium; Walter Fl. Carolin. 140.) Calyx woolly, ſtem-leaves whorled, ſeſſile.—We have been acquainted with this plant ever ſince November, 1793, when a root brought by Mr. John Fraſer from Carolina, flowered for the firſt time in his garden at Chelſea. It was drawn by Mr. Sowerby, but the figure remains unpubliſhed. Michaux in the mean while has named and deſcribed this genus as above, giving an indifferent plate of the only ſpecies known to him, which, he ſays, grows in the dryeſt fir woods of

Carolina and Georgia, and which is the very ſame as Mr. Fraſer's, in whoſe herbarium we have ſeen a ſpecimen from Mr. Walter, who named it, with a mark of doubt, *Chryſoſplenium oppoſitifolium*, not being furniſhed with ſufficient materials to judge how far he was correct or not. Michaux has given a ſpecific character, a perilous attempt, and indeed an abſurd one, for a ſolitary ſpecies, as it can only by accident ſerve to contraſt that ſpecies with others as yet unknown. The *Root* is perennial, rather woody, ſtem a foot or more in height, erect, round, woolly, ruſty-coloured, leafy, branched and forked, many-flowered. *Leaves* nearly entire, ſomewhat undulated; green, ſcattered with looſe, deciduous, ruſty down above; denſely woolly and whitiſh, with ruſty veins, beneath: the *radical* ones cluſtered, obovate, two inches in length, on broadiſh woolly footſtalks about half as long, ſpreading: *ſtem-leaves* in numerous rather diſtant whorls, three or four in a whorl, ſeſſile, ſcarcely an inch long, unequal, pointed. *Stipulas* none. *Bracteas* either terminal or from the forks of the ſtem, ſolitary, ſeſſile, cup-ſhaped, bluntly toothed, woolly, containing eight, ten, or more inodorous *flowers* on ſimple, ſlender, woolly *ſtalks*, each joined in the middle, and ſwelling upwards. Segments of the *calyx* elliptical, broad, obtuſe, white at the edge, green clothed with ruſty wool at the back. The baſe of the *ſtamens*, and ſummit of the *flower-ſtalks*, are tinged with purple. *Fruit* covered by the cloſed internal ſegments of the calyx, become contracted at their baſe, and a little undulated.

2. E. *parvifolium*. Calyx naked. Stem-leaves ſtalked, alternate, ovate, revolute.—Gathered in California by Mr. Archibald Menzies. The *ſtem* is ſhrubby, branched, leafy, with a deciduous, nearly ſmooth bark. *Leaves* alternate or cluſtered, about a quarter of an inch long, ovate, obtuſe, revolute, almoſt if not quite entire; ſmooth and ſhining above; denſely clothed with ruſty wool beneath. *Footſtalks* half as long as the leaves, very woolly, dilated at their baſe, but not quite embracing the ſtem. *Flowers* very numerous, in denſe, globular, woolly tufts, one terminating each branch, and ſurmounted by another, on an elongation of the ſame branch, two inches above it. *Flower-ſtalks* ſmooth. *Calyx* ſmooth, or very ſlightly downy at the back, its ſegments oblong, obtuſe, keeled, entire, not wavy. We have not ſeen the radical leaves, nor been able to inveſtigate the *bracteas*. The round tufts of very copious flowers, and the ſtalked ſcattered ſmall leaves, at once diſtinguiſh this ſpecies.

3. E. *latifolium*. Calyx naked. Stem-leaves ſtalked, alternate, heart-ſhaped, undulated. Foot-ſtalks embracing the ſtem.—Gathered in California by Mr. Menzies, with the laſt. *Stem* ſhrubby. *Branches* round, woolly, leafy. *Leaves* alternate, two inches long, heart-ſhaped, bluntiſh, undulated and criſped at the edge; covered with a web of deciduous white down above; very woolly and white beneath. *Footſtalks* as long as the leaves, woolly, ſheathing the ſtem with their dilated baſes. Some leaves are cluſtered about the end of each branch. *Flowers* not larger than in E. *parvifolium*, and, as in that ſpecies, very numerous in globoſe woolly tufts, terminating elongated, naked, woolly branches. Segments of the *calyx* obovate, keeled, ſomewhat undulated.

The addition of theſe two ſpecies confirms the very natural genus of *Eriogonum*, which in the Linnæan ſyſtem ſhould immediately follow *Rheum*. Probably more ſpecies are to be found in the unexplored wilds of North America. Thoſe we have deſcribed would all certainly bear the climate of Britain, and though not ſplendid plants, are worthy of cultivation for their ſingularity. Their qualities cannot be ſuppoſed different from *Polygonum* and *Atraphaxis*. S.

ERIOPHORUM, from εριον, *wool*, and φερω, *to bear*, alluding to the woolly or cottony tufts borne by the plant when in ſeed. Cotton-graſs.—Linn. Gen. 30. Schreb. 41. Willd Sp. Pl. v. 1. 312. Sm. Fl. Brit. 58. Juſſ. 27. Gærtn. t. 2. Claſs and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juſſ.

Gen. Ch. *Spike*, or rather *Catkin*, imbricated every way: ſcales ovate-oblong, flat, ſlightly inflexed, pointed, membranous, looſe, ſeparating the flowers. *Cor.* none. *Stam.* Filaments three, capillary, anthers erect, oblong. *Piſt.* Germen ſuperior, very ſmall; ſtyle thread-ſhaped, the length of the calyx-ſcale; ſtigmas three, longer than the ſtyle, reflexed. *Peric.* none. *Seed* triangular, pointed, ſurrounded at the baſe with numerous hairs longer than the ſpike.

Eſſ. Ch. Glumes chaffy, imbricated every way. Corolla none. Seed one, inveſted with very long hairs.

Six ſpecies are deſcribed by Willdenow, four of which are found in Britain, *viz.* *E. vaginatum*, Engl. Bot. t. 873; *polyſtachion*, t. 563; *anguſtifolium*, t. 564, long confounded with the laſt; and *alpinum*, t. 311. The exotic ſpecies are, *E. virginicum*, Linn. Sp. Pl. 77; and *cyperinum*, ibid; both natives of North America. The latter has browner and ſhorter hairs to the ſeed than any other, ſo as to have nothing of their ſtriking appearance. The whole genus grows in a turfy ſoil, generally in wet places, to which the firſt ſpecies is an occaſional exception, being ſometimes found on dry mountainous heaths. Some German botaniſts have lately diſtinguiſhed from the *vaginatum*, one which they name *E. Scheuchzeri*. This is *Eriophorum*, n. 1332 β. Hall. Hiſt. v. 2. 175. (Juncus alpinus, capitulo tomentoſo majori; Scheuchz. Prod. 27. t. 7. f. 2.) It has creeping *roots*, ſolitary *ſtems*, not half ſo tall, but much ſtouter than thoſe of *vaginatum*, with a much leſs remarkable ſheath. The *leaves* alſo are very ſhort; the hairs of the *ſeed* very denſe and remarkably delicate. It grows in the moſt elevated marſhy paſtures of the Alps, or about the boggy borders of Alpine lakes, as mentioned by Scheuchzer, and is undoubtedly a diſtinct ſpecies.

ERIOPHORUS, Bulbus, the *Woolly Bulb*, βολβος εριοφορος of Theophraſtus, book vii. chap. 13, who mentions it as "growing on the ſhore, and having between its outer coats and the inner part, which is eatable, a woolly ſubſtance, of which various garments are woven." Pliny obſerves, that Theophraſtus does not inform us in what country this is practiſed. Dodonæus, among the moderns firſt inſtituted an inquiry into this bulb, Hiſt. Stirp. 692, giving a figure, communicated by a friend of whoſe fidelity he is very unwilling to doubt, of a plant hitherto unſeen by any other mortal. It has ſcaly bulbs, more reſembling tuberous roots inveſted with the permanent baſes of the foliage; long ſword-ſhaped leaves: and large ſolitary flowers, unlike every thing known in the vegetable world, being formed of five denſely ſhaggy ovate ſpreading petals, and a ſixth ſtanding upright in the place of the ſtamens and piſtils. This cut has always been judged fictitious, and, if true, it would not anſwer to the deſcription of Theophraſtus. Dodonæus, moreover, figures the *Scilla hyacinthoides* as one kind of *Bulbus eriophorus*, and refers to Cluſius, who, in his Hiſt. Plant. 173, gives *Scilla peruviana* for another. Both theſe bulbs, and, indeed, ſome others, have, in fact, a woollineſs about their upper part when the coats are torn aſunder, apparently conſiſting of their large and tenacious ſpiral-coated ſap-veſſels; but the quantity or quality of this wool is not, in any inſtance that has come under our inſpection, by any means adequate to the uſes mentioned in Theophraſtus.

ERIOSPERMUM, from εριον, *wool*, and σπερμα, *ſeed*. Jacq. Coll. v. 5. 72. Willd. Sp. Pl. v. 2. 110. Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Aſphodeli*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* bell-ſhaped, permanent, of ſix ovate, equal, keeled petals, three of which are exterior and moſt expanded. *Stam.* Filaments ſix, ſhorter than the corolla, awl-ſhaped, uniform, dilated at the baſe, ſmooth; anthers incumbent, oval, two-lobed. *Piſt.* Germen ſuperior, ovate, with ſix ribs; ſtyle erect, angular, as long as the ſtamens; ſtigma ſimple, obtuſe. *Peric.* Capſule of three cells and three valves; partitions from the centre of each valve. *Seeds* ſeveral, affixed to the lower part of each partition, roundiſh, inveſted with long prominent woolly hairs.

Eſſ. Ch. Corolla of ſix petals, bell-ſhaped, permanent. Filaments broad at the baſe. Capſule of three cells. Seeds inveſted with wool.

This genus, than which none can be more natural, either with reſpect to character or habit, was eſtabliſhed by Jacquin in the fifth or ſupplemental volume of his Collectanea, upon the *Ornithogalum capenſe* of Linnæus and Thunberg, with two other ſpecies. They all agree in their tuberous root; radical, ſtalked, ſolitary, elliptic-oblong, entire, involute leaves; and tall, naked, racemoſe, many-flowered ſtalks. The flowers are ſmall; petals white with reddiſh, brown, or greeniſh keels.—They are all delineated in Jacquin's Icones Plant. Rarior. v. 2, as follows.

1. E. *latifolium*, t. 420. (Ornithogalum capenſe; Linn. Sp. Pl. 441. Commel. Hort. v. 2. t. 88.) Leaves broadly elliptical, ſomewhat heart-ſhaped, recurved.—The *leaves* are of a dark ſhining green. Partial *flower-ſtalks* two inches long. *Petals* with a roſe-coloured rib.

2. E. *lancifolium*, t. 421. Leaves ovato-lanceolate, acute, erect.—The upper ſide of the *leaves* is repreſented glaucous by Jacquin, their backs of a graſs green. Partial *flower-ſtalks* but an inch long. *Petals* with a browniſh rib.

3. E. *parvifolium*, t. 422. Leaves elliptical, obtuſe, erect, flat. The *leaves* of this are glaucous, reticulated, and much ſmaller than in either of the former, being but from an inch and half to two inches long. *Petals* with a green rib. *Partial-ſtalks* an inch long, ſpreading.

All theſe ſpecies are natives of the Cape of Good Hope. We ſuſpect that Bengal and the coaſt of Guinea may afford one or two more, but we are not furniſhed with materials ſufficient to aſcertain them completely.

ERIOSTEMON, from εριον, *wool*, and στημων, *a ſtamen*, alluding to the fringed filaments. Sm. Tranſ. of Linn. Soc. v. 4. 221. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Rutaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five deep ſegments, nearly equal, permanent. *Cor.* Petals five, ovate, ſeſſile, regular and equal, ſomewhat ſpreading, moſtly five times as long as the calyx, ſometimes rough, inſerted under a glandular nectary, which ſurrounds the baſe of the germen. *Stam.* Filaments 10, awl-ſhaped, flattened, clothed or fringed with fine ſpreading hairs; anthers on terminal ſtalks, roundiſh with a ſmall point, two-lobed, incumbent, ſmooth. *Piſt.* Germen of five lobes, ſuperior, ſtanding on the nectary, each lobe ſomewhat ovate, triangular, acute, ſoon ſpreading; ſtyle central, from the baſe of the germen, erect, cylindrical, elongated after flowering, ſmooth; ſtigma capitate, with five notches. *Peric.* Capſules five, connected by their baſe, ovate, compreſſed, coriaceous, of two valves, encloſing an elaſtic, cartilaginous, bivalve arillus. *Seeds* ſolitary, kidney-ſhaped, brown, ſmooth.

Eſſ. Ch. Calyx in five deep ſegments. Petals five, ſeſſile. Stamens flat, fringed. Anthers ſtalked, terminal. Style from the baſe of the germen. Capſules five, combined, ſeated on a glandular nectary. Seeds encloſed in an arillus.

Obſ. Some ſpecies have a four-cleft flower, with but eight ſtamens, and others have five of their 10 ſtamens imperfect and abortive.—This genus differs from *Boronia*, Sm. Tracts on Nat. Hiſt. 287. t. 4—7, in having the anthers upon terminal footſtalks, and the ſtyle from the baſe of the germen; not to mention the flowers being generally five-cleft and decandrous, and the leaves uſually alternate. From *Corræa* and *Crowea*, ſee vol. 10, its differences are evident from the characters there given of thoſe genera. We are happy here to mention that the long-deſired *Corræa rubra* flowered, for the firſt time in Europe, at Meſſrs. Lee and Kennedy's, Hammerſmith, in June 1809.

The ſpecies of *Erioſtemon* in our poſſeſſion are ſix.

1. E. *ſalicifolia*. Willow-leaved Erioſtemon.—Leaves linear-lanceolate, flat, ſtraight, naked on both ſides. Branches ſmooth. Flowers lateral. Gathered near Port Jackſon, New South Wales, by John White, M.D. who communicated dried ſpecimens to us in 1791, but it has not yet appeared in the gardens. This is a very handſome flowering ſhrub, with numerous, alternate, wand-like, leafy, ſmooth, angular *branches*, having indeed much of the habit of *Crowea ſaligna*. *Leaves* alternate, from one to two inches long, but little ſpreading, linear-lanceolate, entire, bluntiſh with a ſmall point, thick and coriaceous, naked and ſmooth on both ſides, beſprinkled with glandular dots, ſcarcely veiny, but marked with an obſolete central rib; their baſe tapering down into a ſhort flat *footſtalk*. *Stipulas* none. *Flowers* pink, reſembling thoſe of *Crowea ſaligna*, on ſhort, ſimple, ſolitary, axillary, angular, downy, bracteated ſtalks. *Bracteas* imbricated, roundiſh, obtuſe, concave, pale, downy, fringed. Segments of the *calyx* much reſembling the bracteas, about a line long, imbricated at their baſe. *Petals* alternate with them, and five or ſix times as long, obovate, ſpreading, bluntiſh, clothed with ſhort, denſe, ſcurfy pubeſcence, eſpecially on the outſide. *Filaments* about one-third as long as the corolla, red, all clothed from the baſe with denſe, white, ſpreading hairs, and terminated by a naked, club-ſhaped, obtuſe, red ſtalk, which in the five innermoſt alternate ones is much longer, thicker, and more glandular, than in the reſt, rendering thoſe ſtamens conſpicuouſly the longeſt; anthers at the top of each ſtalk, incumbent, uniform, all fertile, ovate, of two cells, burſting longitudinally on their inner ſide, tipped with a ſmall, pale, reflexed ſcale or creſt. *Style* ſhorter than the ſtamens.

2. E. *buxifolia*. Box-leaved Erioſtemon.—Leaves elliptical, keeled, revolute, with a recurved point. Branches hairy, round. Flowers lateral.—Gathered near Port Jackſon, by Dr. White. Of this we have two very diſtinct varieties, for conſidering the Proteus-like nature of the leaves in New Holland plants, in which alone theſe differ, we dare not call them diſtinct ſpecies. In one the *leaves* are obovate, narrow at the baſe, bluntly crenate and glandular at the edges; in the other they are broadly elliptical, heart-ſhaped, and embracing the ſtem at their baſe, generally even and entire at their edges, though occaſionally furniſhed, in the very ſame manner, with blunt glandular teeth. In both the *branches* are round, clothed with ſhort prominent hairs. *Leaves* numerous, ſcattered, ſcarcely half an inch long, coriaceous, nearly ſmooth, keeled, with a ſharp recurved point, and a thick, ſlightly revolute, margin. *Flowers* towards the ends of the branches, axillary, ſolitary. *Stalks* rather ſhorter than the leaves, thickened upwards,

ſlightly hairy, with ſeveral minute, crowded, roundiſh, ſmooth *bracteas* a little above their baſe. *Calyx* much reſembling the bracteas. *Petals* whitiſh or roſe-coloured, almoſt as large as in the former, but ſmooth or very ſlightly downy; more ſpreading and recurved. *Filaments* minutely fringed, their terminal ſtalks awl-ſhaped, bearing a few long ſcattered hairs; anthers much like the former but ſhorter, and with a ſhorter broader point. *Germen* ſmooth, with very pointed lobes; ſtyle ſhorter than the ſtamens.

3. E. *ſalſolifolia.* Saltwort-leaved Erioſtemon.—Leaves crowded, linear, obtuſe; flattened above; convex beneath; rough-edged, ſtraight. Flowers terminal.—Gathered by Dr. White near Port Jackſon, with the laſt. It ſeems a more humble ſhrub than either of the foregoing, and has angular *branches*, all over ſcarred where former leaves have ſtood; ſlightly hairy when very young. *Leaves* very numerous, ſomewhat imbricated, half an inch or leſs in length, fleſhy, linear inclining to obovate, obtuſe, flattiſh above, convex beneath, more or leſs rough-edged, and ſometimes otherwiſe pubeſcent, dotted with ſcattered glandular points, which in the dried leaves are prominent tubercles. The baſe tapers down into a very ſhort broad *footſtalk*, articulated with a decurrent prominence of the branch. *Flowers* few, terminal at the top of each branch, on ſhort, ſimple, ſmooth ſtalks, which are minutely bracteated at their baſe. Segments of the *calyx* ſhort, broad and acute. *Petals* recurved, downy, pale red with a darker keel. *Filaments* ſmooth at the baſe, their upper part, and terminal ſtalks, denſely clothed with long, upright, white hairs, almoſt concealing the anthers, which are oblong, with a very minute point or creſt. *Germen* ſmooth, with obtuſe lobes.—The ſtamens in theſe three ſpecies would afford beautiful ſpecific differences, were not thoſe of the leaves more commodious and obvious.

4. E. *uniflora.* Single-flowered Erioſtemon.—Leaves ſcattered, elliptic-lanceolate, ſmooth; paler beneath. Flowers ſolitary, terminal, on ſhort ſtalks. Five of the ſtamens abortive. (Dioſma uniflora; Linn. Sp. Pl. 287. Ait. Hort. Kew. v. 1. 276. Mart. Mill. Dict. v. 2. n. 17. Curt. Mag. t. 273. Schrad. Sert. Hannov. 16. t. 8.)—Native of the Cape of Good Hope, from whence it was ſent to the Kew garden, in 1775, by Mr. F. Maſſon, and is now not unfrequent in collections, being much eſteemed for its beautiful flowers, produced abundantly in the ſpring and early part of ſummer. This is a ſhrub from one to two feet high, much branched, ſtrongly, but not agreeably, aromatic in all its parts. *Branches* leafy, nearly ſmooth. *Leaves* ſcattered, on ſhort, rather hairy, *footſtalks*, elliptic-oblong, often nearly linear, obtuſe, very glandular, paler beneath, very obſcurely crenate, and ſomewhat fringed, varying in length from half an inch to an inch. *Flowers* ſolitary at the end of each branch, but from the number of the ſhort branches they ſometimes appear cymoſe. *Stalks* much ſhorter than the leaves, ſwelling upwards, downy, without bracteas. Segments of the *calyx* near half an inch long, lanceolate, purpliſh, fringed. *Petals* twice as long as the calyx, obovate, pointed, of a ſhining varniſhed white, like porcelain, or often bluſh-coloured above; purpliſh beneath. *Stamens* about the length of the calyx, their filaments all fringed; five of them ſhort, bearing large heart-ſhaped anthers, with greeniſh glandular tips; five much longer and more ſlender, each terminating in a ſmall round ſtalked gland, without any anther, varying in ſize and ſhape. *Germen* globular, clothed with numerous ſtalked nectariferous glands; ſtyle and ſtigma like the other ſpecies. Curtis and Schrader have well deſcribed this plant, but neither of them was ſufficiently acquainted with the real ſpecies of *Dioſma*, now numerous in our gardens, to diſcover that it was generically diſtinct, and that the curious nectary, eſſential to *Dioſma*, was wanting. Schrader endeavours to make his deſcription of that part agree with the generic character, but in vain, and his accuracy would ſoon have diſcovered the truth, had he ſeen a real *Dioſma*. The *Hænkea* of Schmidt in Uſter's Annals, faſc. 6. 117, to which Schrader refers, agrees in generic characters with *Dioſma barbigera* of Linnæus, and not with our *Erioſtemon*.

5. E. *marginata.* Bordered Erioſtemon.—Leaves ſcattered, lanceolate, paler beneath. Flower-ſtalks axillary, twice as long as the leaves, corymboſe. Five of the ſtamens abortive. (Dioſma marginata; Linn. Suppl. 155.). Native of the Cape of Good Hope, raiſed by Meſſrs. Lee and Kennedy, with whom it flowered in June 1809. It agrees very much in habit with the laſt, but has a more pleaſant ſmell, like ſaſſafras or myrrh, when rubbed, and differs very eſſentially in the great length of its *flower-ſtalks*, which are not terminal, but ſpring from the boſoms of ſeveral of the uppermoſt leaves, and riſing above the ſummit of the branch, make a ſort of corymbus. A pair of lanceolate *bracteas* grow either near the top of each ſtalk, or towards its middle, or in our garden ſpecimens, near the baſe. Their preciſe ſituation ſeems not characteriſtic of any ſpecific difference. The ſegments of the *calyx* vary in breadth, and are often fringed, ſometimes ſmooth. *Petals* moſtly notched at the extremity, but otherwiſe like thoſe of *E. uniflora*, as are alſo the *ſtamens*. The *leaves* vary greatly in length and breadth. Their membranous margin, whence the name is taken, is often very conſpicuous in the dried plant, but we cannot perceive it in the living one, nor even in our garden ſpecimens when dried, ſtill we would not preſume to change a name founded in truth, though not always applicable; otherwiſe *pedunculata* would be a more eligible one. Our remarks on this ſpecies are made from various ſpecimens named and unnamed in the Linnæan herbarium, which vary greatly in the hairineſs or ſmoothneſs of their branches and leaves, as well as the form and breadth of the calyx, but we can find no poſitive ſpecific diſtinction among them. The leaves in ſome are nearly oppoſite, but never conſtantly ſo. We know, from frequent obſervation, that the laſt ſpecies is extremely variable, and are perſuaded that this is ſubject to equal differences. The infloreſcence, however, of each is ſo conſtant, that they can never be confounded together.

6. E. *paradoxa.* Various-leaved Erioſtemon.—Leaves lanceolate, revolute, downy beneath; ſimple, ternate, or pinnate. Flowers lateral, four-cleft. Stamens eight. Sent from Port Jackſon, New South Wales, by Dr. White.—*Stem* ſhrubby, with numerous, oppoſite, round, rough, leafy *branches*. *Leaves* an inch, more or leſs, in length, lanceolate, obtuſe, entire, ſomewhat revolute; ſmooth and naked above; clothed with denſe, white, entangled or ſtarry pubeſcence beneath. In one variety they are ſimple, almoſt perfectly oppoſite, on ſhort footſtalks; in another ſmaller, ternate, ſeſſile on one common winged ſtalk, which is about half the length of the lateral pair; in a third they are as large as in the firſt, and are either ternate or conſiſt of two pair and an odd one, all ſeſſile on a ſimilar, but longer, winged ſtalk. The pinnate and the ternate kinds are unqueſtionably but varieties of each other, nor can we think the firſt a diſtinct ſpecies, however paradoxical our opinion may ſeem. The *flowers* of all are exactly alike. *Flower-ſtalks* copious, axillary, ſolitary, ſhorter than the leaves, ſimple, ſingle-flowered, angular, clothed with ruſty ſtarry ſcales or pubeſcence. *Bracteas* two, towards the middle of each ſtalk, obovate, ruſty, ſmall. *Calyx* downy and ruſty,

quadrangular at the baſe, its four ſegments ovate, broad, keeled. *Petals* four, thrice as long as the calyx, elliptical, keeled, roſe-coloured, ſmoothiſh above, downy beneath. *Filaments* eight, all nearly equal, rather ſhorter than the calyx, red, thick, obtuſe, glandular, fringed in their lower part; anthers ſhort and roundiſh, each on a ſhort, ſlender, white, terminal ſtalk, their white tip or creſt very minute. *Germen* reddiſh, with four blunt lobes.—We have heſitated whether to refer this plant to *Boronia*, with which genus it agrees beſt in habit, and number of parts in the fructification, but the inſertion of the anthers and of the ſtyle have always appeared to us rather like *Erioſtemon*. We have never ſeen it alive. Future obſervations on the living plant may correct our preſent determination. It appears to be one of the prettieſt ſhrubs that New South Wales affords, and would be a welcome acquiſition for the Engliſh conſervatories. S.

ERIOX, or Erox, in *Ichthyology*, a ſpecies of Salmo, called by Pennant, Willughby, and Ray the *Grey*. See Salmo.

ERISANA, in *Ancient Geography*, a town of Spain, in Luſitania.

ERISKAY, in *Geography*, one of the weſtern iſlands of Scotland, ſeparated from South Viſt by a narrow ſtrait, called "Eriſkay Sound;" about five miles in circumference.

ERISMA, in *Botany*, according to the author of the name, is derived from ερειδω, *to prop*, or *ſupport*, and not from εριζω, *to diſpute*, or *contend*. Rudge Pl. Guian. 7. Claſs and order, *Monandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth of one leaf, permanent, downy on both ſides, in four deep unequal ſegments, one of which is much the longeſt, irregular, obtuſe, behind the larger petal; the reſt ſharper, and half-lanceolate. *Cor.* Petals two, oppoſite, unequal, emarginate, the uppermoſt united with the calyx betwixt its leſſer ſegments, broad, roundiſh; its baſe ending in a horn-like, blunt *nectary*, the length of the petal, downy externally, like the calyx; the lowermoſt thrice as long as the other, and broader, inſerted into the receptacle behind the perfect filament. *Stam.* Filaments five; one of them fertile, as long as the upper petal, incurved, inſerted into the receptacle; the other four very ſhort, abortive; anther arrow-ſhaped, narrow. *Piſt.* Germen inferior, oblong, of one cell; ſtyle thread-ſhaped, as long as the filament, aſcending; ſtigma blunt. *Peric.* unknown. Rudiments of *ſeeds* two, oblong.

Eſſ. Ch. Calyx in four deep unequal ſegments. Petals two, unequal; the uppermoſt united with the calyx, ſpurred at its baſe; the lowermoſt inſerted into the receptacle. Fruit with two ſeeds.

E. *floribunda*. Rudge t. 1. Native of Guiana. A tree or ſhrub with round *branches*, when young clothed with ſtarry down of a brown colour. *Leaves* large, nearly oppoſite, elliptical or obovate, obtuſely pointed, entire, ſmooth, with numerous parallel veins. *Stipulas* ſmall, deciduous. *Panicles* large, terminal. *Bracteas* in pairs, very unequal, downy, the ſmalleſt about a line long, the other four lines long, broad and ovate. The *flowers* are very ſmall, and concealed by the *bracteas*. Of their colour or properties we have no account.

ERISMATOLITHUS, in *Natural Hiſtory*, and *Mineralogy*, is the name of a genus in the animal order of remains (*reliquia*, or relics) of a former race of beings, which inhabited the earth or its waters, and includes the *fulciments* or plant-like ſupports which certain animals fabricated for their ſupport and habitation, and which are preſerved in a foſſil ſtate. According to Mr. William Martin (Outlines of the Knowledge of extraneous Foſſils, p. 193.) the eſſential characters or diagnoſtics of the permanent ſpecies in this genus are to be ſought in various parts of the *reliquium*, *e. g.* "In reliquia of cellular fulciments, the ſtirp exhibiting the internal form or ſtructure of the cells: in reliquia of ſolid fulciments, the ſtirp exhibiting its external form." The temporary ſpecies of this genus are to compriſe ſuch cellular fulciments as do not ſhew the ſtructure of their cells, and ſuch ſolid imperfect ſpecimens as are not reducible to known ſpecies. The foſſil corals, corallines, ſponges, &c. rank under this genus. See Reliquia.

ERISTALIS, the name of a ſtone, mentioned by Pliny and the ancients, and of which a very memorable quality is recorded by them, which is, that though it was naturally white, it would occaſionally turn red.

ERISTICI, from ερις, *diſpute*, in *Botany*, ſuch authors as have attempted the ſtudy of that ſcience in a philoſophical way, and have been publicly engaged in diſputes about the true foundation of its ſeveral diſtinctions, &c.

ERITHACE, a name given by the ancients to the yellow matter collected on the hinder legs of the bees after their excurſions in ſearch of the materials for their hives; we uſually eſteem this to be real wax, and the French call it *cire*, brute, or rough-wax; it is certain, however, that though the matter of which wax is to be formed is contained in this ſubſtance, yet the Dutch and ſome other nations have the moſt juſt idea of it, in calling it *pain des abeilles*, or the food of the bees.

This ſubſtance is only the farina of flowers, and no experiment has been able to ſeparate real wax from it. The moſt probable opinion concerning it is, that it ſerves the bees as food, and that after this it is converted in their bowels into the ſubſtance called wax.

ERITHALIS, in *Botany*, Εριθαλις is an ancient name of ſome plant now unknown, derived from εριθαλης, *highly verdant*, or *beautifully leafy*. Browne adopted it for the preſent genus, and was followed by Jacquin and Linnæus.—Browne Jam. 165. Jacq. Amer. 72. Linn. Gen. 95. Schreb. 130. Willd. Sp. Pl. v. 1. 996. Mart. Mill. Dict. v. 2. Juſſ. 206. Gærtn. t. 26. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, cup-ſhaped, with five teeth, permanent. *Cor.* of one petal, deeply five-cleft; tube very ſhort; ſegments of the limb long, lanceolate, recurved. *Stam.* Filaments five, awl-ſhaped, ſpreading, ſcarcely ſo long as the corolla; anthers oblong. *Piſt.* Germen inferior, roundiſh; ſtyle thread-ſhaped, compreſſed in the upper part, the length of the ſtamens; ſtigma acute. *Peric.* Berry globoſe, crowned with the baſe of the calyx, of ten cells, (ſometimes but eight, *Gærtner.*) *Seeds* ſmall, ſolitary, pendulous.

Eſſ. Ch. Corolla in five deep recurved ſegments. Calyx cup-ſhaped. Berry inferior, of ten cells. Seeds ſolitary.

The ſpecies are,

1. E. *fruticoſa*. Linn. Sp. Pl. 251. (E. odorifera; Jacq. Amer. 72. t. 173. f. 23. E. fruticuloſa; Brown. Jam. 165. t. 17. f. 3. Sambucus ligno duro odoratiſſimo; Plum. Ic. 247. t. 249. f. 2.)—Leaves obtuſe. Flower-ſtalks all cymoſe, many-flowered.—Native of Jamaica, and other Weſt Indian iſlands, growing near the ſea-ſide, and very various in height and luxuriance, according to its ſituation. *Stem* ſhrubby, with round, ſmooth *branches*, leafy towards their extremities. *Leaves* oppoſite, ſtalked, obovate, entire, about two inches long, various in breadth, obtuſe, ſmooth and ſhining. *Flowers* white, ſmelling (according to Jacquin) like the common lilac, growing many together, in long-ſtalked, axillary, cymoſe panicles, about the ends of the branches, but they are not terminal as Willdenow deſcribes them. *Berries* purple, the ſize of a pea.—Jacquin

deſcribes another ſpecies or variety, he is doubtful which, with inodorous flowers, whiter berries, and a more humble diffuſe ſtem, growing on barren maritime rocks in the iſland of Curaçao. This we have never ſeen.

2. E. *polygama.* Forſt. Prod. 17.—Leaves acute. Male flowers cymoſe; perfect ones ſolitary.—Gathered by Forſter in the Society Iſlands.—That writer refers to the *Timonius*, Rumph. Amb. v. 3. 216. t. 140, as a narrower-leaved variety of his plant. This is, indeed, to all appearance, an *Erithalis.* Rumphius informs us that it grows in graſſy open hilly places in Amboyna, and the neighbouring iſlands.

The *ſtem* is the height of a man. *Leaves* four or five inches long, and as broad as two fingers, acute at each end. *Flowers* of a dirty white. *Berries* yellowiſh-black, eaten by ſtarlings and other birds. The *roots* are uſed by the natives to chew, along with a ſlight mixture of cloves, nutmegs and ginger, in their maritime excurſions, in which they ſuffer much from cold and other inconveniencies.

ERITRI, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia; 36 miles W. of Smyrna.

ERITZKA, a town of Ruſſia, in the government of Irkutſch; 20 miles E. of Kirenſk.

ERIVAN, called *Perſian Armenia*, *Greater Armenia*, and *Eaſtern Armenia*, a province of Perſia, about 200 leagues in length, and 60 in breadth. See ARMENIA.

ERIVAN, *Irvan*, or *Irivan*, a city of Aſia, and capital of Greater Armenia, or Erivan; ſituated in a plain, ſurrounded with mountains, and watered by two ſmall rivers; large, dirty, and ill built, and but indifferently peopled: the ramparts are of earth; the fortreſs is encompaſſed with a wall of bricks, in which are a palace for the governor, and 800 houſes, inhabited only by Perſians; the Armenians have ſhops there, but muſt not remain during the night. The churches are ſmall, and half buried in the ground, reſembling catacombs; in the town and its environs they reckon 28 convents for devotees of both ſexes, but they are poorly endowed.

ERIX, or ERYX, in *Ancient Geography*, a mountain of Sicily, ſituated towards the weſtern part, near the ſea. Solinus ſays, that it was conſecrated to Venus. Polybius places it between Drepana and Palermo. According to Apollodorus, this mountain derived its name from a ſon of Venus, called *Erix*. It is now called "Monte St. Giuliano," or "Monte di Trapani."—Alſo, a town of Sicily, now "Trapani del Monte," ſituated on the ſummit of mount Eryx, difficult of acceſs, and famous for a temple of Venus, called Erycina. Polybius and Strabo mention this town. Minos decorated this temple with ſuperb ſculpture, and enriched it with ſuch noble offerings, as have claimed for him the honour of being its founder. The victims offered themſelves voluntarily at the altar. The moſt beautiful women in the world were the prieſteſſes, and the Roman ſenators, laying aſide their characteriſtic ſeverity, came hither to indulge in pleaſure with the beauteous Sicilian females, perſuaded they ſhould thus make their offerings acceptable to the goddeſs, and render her propitious. In the time of Strabo the town and temple were much decayed. It is ſaid that Eryx was deſtroyed by Hamilcar, who in the firſt Punic war, A. U. C. 493, removed its inhabitants to Drepanum, which he had built not long before. Nothing now remains but a paltry village, and ſome foundations of a temple.

ERIZZO, SEBASTIAN, in *Biography*, a noble Venetian, was particularly diſtinguiſhed for his knowledge of the medallic ſcience. He publiſhed, in 1559, in Italian, "A Diſcourſe upon Ancient Medals," which has been highly eſteemed for its erudition. He contended for the difference between the medals and coins of the ancients. Erizzo was the author of a treatiſe on "Logic;" a tranſlation of "Plato's Dialogues:" a diſcourſe on "Civil Governments," and ſome other pieces. He died in 1585. Gen. Biog.

ERKELENS, or EREKELENS, probably *Herculanum*, in *Geography*, in the days of the Romans, is an ancient town of France, in the department of the Roer, chief place of a canton, in the diſtrict of Créveldt, with a population of 1340 individuals. It is at a diſtance of about three miles from the river Roer, 15 miles north of Juliers; its ancient fortifications were demoliſhed by the French in 1674. The canton contains 48 communes, and 17,853 inhabitants.

ERLA, a ſmall town of the kingdom of Saxony, in the circle of the Ertzgebirge, at the foot of the mountain called Rothenberg, remarkable for a rich mine of excellent iron, the beſt of the whole of this mountainous diſtrict. Its iron works are celebrated for caſting the beſt ovens and frying-pans in Saxony; there is alſo a manufactory of cannon-balls. There was anciently a ſmall town of the ſame name in Ruſſia, in the government of Riga, not far from Dorpat; but it is now in ruins.

ERLACH, in French *Cerlier*, a ſmall town of Switzerland, in the canton of Berne, at a diſtance of about three quarters of an Engliſh mile from the upper part of the beautiful lake of Bienne, is ſituated on the declivity of the Julimont, or Julius' mountain, for it is proved beyond contradiction that Julius Cæſar eſtabliſhed upon this hill one of his ſtrong entrenched camps. This elevation is alſo called Jolimont, pretty mount, from the beauty of the proſpect, which can be no where more varied, or more intereſting, on account of the number of pictureſque contraſts which it affords. Travellers who wiſh to viſit the famous iſland of St. Pierre, in the lake of Bienne, generally take a boat at Erlach. It has an ancient caſtle, which gave the title of barons to the illuſtrious Swiſs family of the Erlachs, who, from the time of the intrepid Ulrich of Erlach, have held ſuch a diſtinguiſhed place in the annals of their country.

ERLANG, or ERLANGEN, a handſome town of Germany, in the circle of Franconia, in that part of the margraviate of Anſpach Baireuth which was called the principality of Culmbach, on the river Rednitz, 18 miles N.W. of Nuremberg, and 30 miles S. of Bamberg. N. lat. 49° 38′. Until the peace of Tilſit, concluded in July 1807, between France and Pruſſia, this town, and the whole margraviate of Anſpach Baireuth, belonged to the kings of Pruſſia, to whom it had been ceded by the laſt margrave, in 1792: but it is now at the diſpoſal of the French emperor.

Erlang is divided into the old and new town; the latter is alſo called Chriſtian Erlang, from the name of its founder, the margrave Chriſtian Erneſt, who built it in the year 1686 to accommodate ſeveral families of Proteſtant French refugees. The ſtreets of both towns are regular and ſpacious: there are two handſome ſquares, and ſome fine churches. The principal manufactures eſtabliſhed by the French refugees were thoſe of hoſiery and of hats, which are ſtill flouriſhing. In 1742 the univerſity of Baireuth was alſo removed to Erlang.

ERLAU, in Latin *Eger*, or *Agria*, a town of Upper Hungary, in the diſtrict of Heves, near which there is a fine hot mineral ſpring, which is uſed for bathing. It is the ſee of a biſhop, and the ſeat of an univerſity, the buildings of which are very fine: the profeſſors are well accommodated, the lecturing rooms very good, and the chapel, library, and public hall extremely elegant. The ſee of Erlau is one of the richeſt in the kingdom. The town is in general ill built, the only good houſes are thoſe of the canons of the cathedral. There is, however, a Turkiſh tower in good condition. The only remarkable manufactures are thoſe of wax and of leather. The neighbourhood of Erlau is famous for an excellent ſort of Hungary wine, little inferior to the beſt Burgundy.

ERLEBACH, a river of Germany, which riſes in the duchy of Stiria; 6 miles below Ips.

Erlebach, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, on the Main; 3 miles N.N.W. of Clingenberg.

ERLENBACH, a town of Germany, in the circle of Franconia, and county of Wertheim; 10 miles N.N.E. of Wertheim.

ERMELAND, or Ermland, in Latin *Varmia*, one of the four ſubdiviſions of that part of the kingdom of Pruſſia which is called Eaſtern Pruſſia. In ancient times, two-thirds of this country belonged to the biſhops of Ermeland, who were princes of the German empire, and one-third to the chapter of the cathedral church of Frauenburg. The biſhop enjoys ſtill a very conſiderable income.

Ermeland is particularly remarkable for its hemp and flax, and its linen yarn, great quantities of which three articles are annually exported to England in time of peace. The principal towns are Frauenburg, the ſee of the biſhop; Braunſberg, the chief city, which alone exports yarn to nearly the annual amount of two millions of guilders; Heilſberg, Allenſtein, Röſſel, Wormdit, &c.

ERMENEK, a town of Aſiatic Turkey, in the province of Caramania; 63 miles S. of Cogni.

ERMENONVILLE, a ſmall town of France, in the department of the Oiſe, chiefly remarkable for its beautiful park, and a caſtle, which derives ſome celebrity from having belonged to the handſome Gabrielle, miſtreſs of king Henry IV. of France. But Ermenonville is become far more famous in modern times, for having been the laſt retreat of the eloquent and miſanthropic Jean Jaques Rouſſeau, who died here on the 2d of July 1778, and to whom a handſome monument has been erected in a ſmall iſland called the iſland of poplars, which is in the middle of a fine lake. This monument is remarkable for the beautiful ſimplicity of its inſcription.

> “ Ici repoſe l'homme de la nature et de la vérité.”
>
> “ Here repoſes the man of nature and of truth.”

ERMESIA, a name given to a compoſition uſed among the ancients, and famous for its effects in making people beget handſome children. It conſiſted of honey, myrrh, ſaffron, and palm-wine, all beaten together. This maſs was to be taken mixed in milk. The women took it as well as the men, and many had great faith as to its effects.

ERMIJA, in *Geography*, a town of Spain, in the province of Biſcay; 16 miles E.S.E. of Bilbao.

ERMIL, a town of Ruſſia, in the government of Tamboo; 44 miles S. of Tamboo.

ERMIN, or Ermine, in *Heraldry*, denotes a white field or fur, powdered or interſperſed with black ſpots, called powdering. See Fur.

It is ſuppoſed to repreſent the ſkin of an animal of the ſame denomination. In effect, there is no animal whoſe ſkin naturally correſponds to the herald's ermin.

The animal is milk white; and ſo far is it from having ſpots, that tradition reports, that it will rather die, or be taken, than ſully its whiteneſs. Whence its ſymbolical uſe.

But white ſkins having for many ages been uſed for the linings of the robes of magiſtrates and great men; the furriers at length, to add to their beauty, uſed to ſew bits of the black tails of thoſe creatures upon the white ſkins to render them the more conſpicuous. Which alteration was introduced into armoury.

The ſable ſpots in ermin are not of any determinate number, but they may be a greater or leſs, at the pleaſure of the painter or furrier.

Ermin, an order of knights, inſtituted in 1450 by Francis I. duke of Bretagne, and formerly ſubſiſting in France. The collar of this order was of gold, compoſed of ears of corn in ſaltier; at the end of which hung the ermin, with this inſcription, *a ma vie*. But the order expired when the dukedom of Bretagne was annexed to the crown of France.

ERMINE', a croſs erminé is a croſs compoſed of four ermine ſpots.

It muſt be obſerved, that the colours in ſuch arms are not to be expreſſed, becauſe neither the croſs nor the arms can be of any colour but a white and black.

Colombiere blazons it quatre queues d'ermine en croix. The editor of Guillim deſcribes it thus; a croſs of four ermines; or, more properly, four ermine ſpots in croſs. It is the coat of Hurſton in Cheſhire.

Ermine, *timbre of*. See Timbre.

Ermine, in *Zoology*. See Mustela *Erminea*.

Ermines is uſed by ſome Engliſh writers for the reverſe of ermine, *i. e.* for white ſpots on a black field; but on what foundation nobody can tell; for the French, from whom we have our heraldry, have no ſuch term; but call this black powdered with white contre-ermine; as denoting the counter, or reverſe of ermine, which is white powdered with black.

ERMINEUM Animal, *ſtoat*, or *ermine*, the creature whoſe ſkin is the ermine, ſo much eſteemed as a fine fur.

This creature is properly a ſpecies of weaſel, and is called by Mr. Ray, and other authors, muſtela candida, the white weaſel, and by Linnæus muſtela erminea. It is in all reſpects like the common weaſel, and is all over of a pure ſnow white, except the tip of the tail, which is of as beautiful a black, and it has a little yellowiſh grey about the eyes, and a mark or ſpot of the ſame colour on the head, another on the ſhoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the ſeaſon of the year. It is frequent about rivers, and in meadows, in thoſe countries which produce it, and feeds on moles, mice, and other ſmall animals. The ſkins and tails are a very valuable article of commerce in Norway, Lapland, and Ruſſia, and other cold countries, where they are found in prodigious numbers, and regularly change their colour in winter, becoming white. In Siberia, they burrow in the fields, and are taken in traps, baited with fleſh. In Norway they are ſhot with blunt arrows, or taken in traps. The ſtoat is ſometimes found white in Great Britain, and called the white weaſel. See Mustela.

ERMINITES ſhould ſeem a diminutive of ermines, and naturally to ſignify little ermines; but it is otherwiſe. Erminites expreſſes a white field powdered with black; only that every ſpot has a little red hair therein.

Some authors uſe the word erminites for a yellow field powdered with black, which the French expreſs much better by, or, ſemèe d'ermines de ſable.

ERMINOIS expreſſes an or field, with ſable powdering.

ERMS, in *Geography*, a river of Germany, which runs into the Danube, four miles S.W. of Nurtlingen, in the circle of Swabia.

ERMSLEBEN, a town of Germany, in the circle of

Lower Saxony, and principality of Halberſtadt; 14 miles S. E. of Halberſtadt.

ERNANI, a town of Spain, in the province of Guipuſcoa; 5 miles S. of Sebaſtian.

ERNATIA, a town of Aſiatic Turkey, in the province of Natolia; 16 miles N. W. of Satalia.

ERNE, the name of a river in Ireland, which riſes near the boundaries of the counties of Longford and Cavan, and paſſes through loughs Gawnah and Oughter in the latter county. From the laſt of theſe lakes it continues a northern direction till it flows into lough Erne, a little below Belturbet. The ſuperfluous waters of this lake are diſcharged by a rapid current of about ſeven miles, which is alſo called Erne, and which falls into the bay of Donegal, below Ballyſhannon.

Erne-*Lough*, a lake of the county of Fermanagh, Ireland, which is ſuppoſed to occupy above 45,000 acres. It conſiſts properly of two lakes connected by a broad winding channel of about ſix miles. The upper lake is nine miles long, and from one and a half to five wide; the lower lake extends in length about ten miles, and in breadth from two to eight. Both theſe lakes are full of iſlands, being ſaid to contain from three to four hundred, the number varying according to the ſeaſon, being more numerous in winter than in ſummer, on account of the greater height of the water. Some of theſe iſlands are large and inhabited, and many of them well wooded, ſo that the variety of intereſting proſpects afforded by them and the neighbouring coaſt is aſtoniſhing, and far ſurpaſſes the power of deſcription. A canal to open the navigation from the lough to the ſea has been projected, and would be attended with great advantage to the whole of Fermanagh and Cavan. It is alſo probable that a conſiderable part of the lake might be drained, and notwithſtanding its beauty, it is a pity that ſo many acres ſhould be unprofitable.

ERNE'E, a ſmall town of France, in the department of Mayenne, chief place of a canton, in the diſtrict of Mayenne, with a population of 4740 individuals. It is ſituated on the river Ernée, 15 miles W. of Mayenne. The canton contains 6 communes and 15,053 inhabitants, on a territorial extent of 232 kilometres and a half.

ERNES, in our *Old Writers*, ſignify the looſe ſcattered ears of corn that are left on the ground, after the binding or cocking of it.

It is derived from the old Teutonic *ernde*, harveſt; *ernden*, to cut or mow corn. Hence ern is, in ſome places, to glean.

ERNEST, in *Biography*. See Mansfeld.

Ernest *Town*, in *Geography*, a townſhip of Upper Canada, in the midland diſtrict, the fineſt above Kingſton, ſheltered from lake Ontario by Amherſt iſland, which lies in its front.

ERNESTI, John Augustus, in *Biography*, was born in Auguſt, 1707, at Tennſtadt, where his father was ſuperintendant. He ſtudied at Pforta, and ſoon diſplayed uncommon talents; he afterwards applied himſelf to the ſtudy of theology at Leipſic, and took his degree of M. A. in the year 1730. In 1734, having been elected rector of Thomas's ſchool in the room of Geſner, ancient literature, and thoſe branches of knowledge connected with it, became the principal objects of his purſuit. The ſucceſsful application of his talents in this department of knowledge cauſed him to be choſen, in 1742, extraordinary profeſſor of ancient literature, in 1756 he was elected public profeſſor of eloquence, and in 1758, he was made doctor and profeſſor of theology. He died in the year 1781, having, till within the laſt two or three years, been inceſſantly engaged in the laborious diſcharge of his public duties. For twenty years and more he paſſed the greater part of each day in inſtructing others, yet he found ample time for the publication of many original works, and for editing various ancient authors. Among the latter may be mentioned, 1ſt, the Memorabilia of Xenophon, which has been frequently republiſhed in this and other countries. 2d, Ciceronis Opera omnia cum clave, in 6 vols. The Clavis has been publiſhed ſeparately. Erneſti, in preparing this work for the preſs, employed the beſt and oldeſt editions of Cicero, as well as ſeveral MSS.; he examined critically the text of Gruter, corrected in it a great many faults, and in his ſhort notes, he has in various places illuſtrated, and in others reſtored the original. He alſo gave the world new editions with notes of Suetonius, Tacitus, Homer, &c. He publiſhed Ariſtophanis Nubes, cum ſcholiis antiquis et Prefat; Hederici Lexicon, multis vocabulorum millibus auctum; a New Theological Library, in 11 volumes; and "Inſtitutio interpretis Novi Teſtamenti," which has paſſed through ſeveral editions. Alberti of Leyden was ſo much delighted with this, that he called it "The Golden Work." A new edition of it was publiſhed in Holland within a few months after it was printed at Leipzic. The extenſive talents and ſober judgment of Erneſti enabled him not only to embrace every department of literature, but to examine and illuſtrate many of its obſcurities and difficulties. He poſſeſſed a ready and retentive memory, and, above all, an honeſt and upright heart. "Though," ſays his biographer, "the ſerioufneſs of his countenance beſpoke a character hoſtile to every kind of levity, and born for labours that require great vigour and exertion, he was a friend to chearfulneſs, and his company, on account of his eaſy behaviour and good humour, which was often heightened by Ciceronian wit, but confined within the boundaries of virtue and decency, made his converſation much ſought after, and highly agreeable." Gen. Biog.

ERNODEA, in *Botany*, from ἐρνώδης, *branched*, ſo that it ought rather to be written *Hernodea*. Swartz. Prod. 29. Fl. Ind. Occ. v. 1. 223. Schreb. 788. Willd. Sp. Pl. v. 1. 611. Mart. Mill. Dict. v. 2. Sm. Prod. Fl. Græc. Sibth. v. 1. 98. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*.

Gen. Ch. *Cal.* Perianth ſmall, ſuperior, in four deep, upright, acute, equal, permanent ſegments. *Cor.* of one petal, ſalver-ſhaped; tube elongated, quadrangular; limb in four deep, lanceolate, recurved ſegments. *Stam.* Filaments four, inſerted into the tube towards the middle, awl-ſhaped, longer than the tube; anthers erect. *Piſt.* Germen ſquare, inferior; ſtyle thread-ſhaped, about as long as, or longer than the ſtamens; ſtigma obtuſe, notched. *Peric.* Berry roundiſh, crowned with the calyx, having a furrow at each ſide, and conſiſting of two cells. *Seeds* ſolitary, hemiſpherical, ſtriated.

Eſſ. Ch. Corolla of one petal, ſalver-ſhaped. Calyx in four deep ſegments. Style ſimple. Berry inferior, of two cells. Seeds ſolitary.

1. E. *littoralis*. Swartz. Fl. Ind. Occ. v. 1. 224. t. 4. Vahl. Symb. v. 2. 28. (Thymelæa humilior, foliis acutis atrovirentibus; Sloane Jam. v. 2. 93. t. 189. f. 1, 2.)—Stem ſquare, ſmooth. Leaves nearly ſeſſile, acute, with a ſpinous point. Gathered by Sloane, Browne, and Swartz, in Jamaica. The latter informs us that it grows in gravelly places by the ſhore, or on calcareous rocks. *Root* perennial. *Stems* procumbent, creeping, rather woody, with numerous, long, creeping or pendulous *branches*, which are ſtraight, ſquare, ſmooth, ſomewhat jointed, not much divided, but bearing numerous, alternate, ſhort, leafy, ſimple, lateral branches. *Leaves* crowded, oppoſite, croſſing each

other in pairs, nearly ſeſſile, about an inch or more in length, elliptic-lanceolate, acute at both ends, entire, very ſmooth, ribbed, rigid, of a dark green, tipped with a ſpinous point. *Stipulas* united with a ſtem between the very ſhort footſtalks, each crowned with three briſtles, the middle one longeſt. *Flowers* axillary, ſolitary, ſeſſile, yellowiſh. Many of them, according to Dr. Swartz, have no piſtils.

2. E. *montana*. Sm. Fl. Græc. Sib. v. 2. t. 143, unpubliſhed. Prod. n. 343. (Aſperula calabrica; Linn. Suppl. 120. Willd. Sp. Pl. v. 1. 577. L'Herit. Stirp. v. 1. 65. t. 32. Rubeola cretica fœtidiſſima fruteſcens myrtifolia, flore magno ſuaverubente; Tourn. Cor. 5.)—Stem round, downy. Leaves ſtalked, blunt, pointleſs.—Native of mountainous places in Crete, Sicily, and the ſouth of Italy. Much ſmaller than the laſt, except in its *flowers*, which are larger, cluſtered about the ends of the branches, and of a fine roſe-colour. The *ſtems* are much branched, woody, decumbent. *Leaves* on ſhort ſtalks, oppoſite, about half an inch long, elliptic-lanceolate, bluntiſh at both ends, entire, revolute, without any terminal ſpine, much more pliable than in the former; dark green above; pale beneath; roughiſh occaſionally. When bruiſed they have a very diſagreeable ſtercoraceous ſmell. *Stipulas* with a ſimple lanceolate point. *Branches* more or leſs downy when young.—Authors have greatly differed about the genus of this plant. By the older ones it has been taken for a *Rubia*, a *Valeriana*, a *Thymelæa*, and a *Nerium* or *Oleander*; by modern writers it has been referred to *Aſperula*, *Sherardia* and *Pavetta*. We hope to be nearer the truth than our predeceſſors; at leaſt its technical generic characters agree well with Swartz's *Ernodea*, nor do we find any great diſcordance in the habit.—This beautiful plant emulates the *Daphne Cneorum* in colour and general aſpect, and would be ſcarcely leſs admired in our gardens, to which it is, as yet, a ſtranger.

ERNSPACH, in *Geography*, a town of Germany, in the circle of Franconia, and principality of Hohenloe; ſix miles N. of Okringen.

ERNSTEIN, a caſtellated town of Germany, in the circle of the Lower Rhine, and electorate of Cologne; eight miles E. of Lintz.

ERNSTHOFEN, a town of Germany, in the circle of the Upper Rhine, and principality of Heſſe Darmſtadt; 10 miles S. of Darmſtadt.

ERNSTTHAL, a ſmall town of the kingdom of Saxony, in the county of Schonburg, cloſe by Hohnſtein, at the foot of a mountain called the Pfaffenberg, with a population of about 2000 individuals. It has a few cotton and linen manufactories.—Alſo, a ſmall town of Germany, in the duchy of Saxe-Coburg, which has a conſiderable glaſs manufactory; in the ſpace of thirteen weeks, or three calendar months, they make 216,000 glaſſes, 1000 of which uſed to be ſold, in 1788, for 3⅓ rix dollars, or not quite twelve ſhillings ſterling.

ERODINUM, a word uſed by ſome of the enthuſiaſtic writers in alchemy, to ſignify the prognoſtic, good or bad, of any operation.

ERODIUM, in *Botany*, from ερωδιος, *a heron*, becauſe the fruit reſembles the head and beak of that bird. For a ſimilar reaſon it is called in Engliſh Stork's-bill. L'Heritier. Geraniolog. unpubliſhed. Ait. Hort. Kew. v. 2. 414. Sm. Fl. Brit. 727. Willd. Sp. Pl. v. 3. 625. Sibth. Oxon. 211. (Geranium; Linn. Gen. 350. Schreb. 458. Juſſ. 268. Gærtn. t. 79, *moſchatum*.) Claſs and order, *Monadelphia Pentandria*. Nat Ord. *Gruinales*, Linn. *Gerania*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, pointed, concave, permanent leaves. *Cor.* Petals five, obovate, ſpreading, rather longer than the calyx, generally more or leſs irregular. *Nectary* of five glands between the petals. *Stam.* Filaments 10, awl-ſhaped, united by their baſe into a ſort of cup; five of them fertile, nearly as long as the petals; the alternate five ſhorter and barren; anthers five, oblong, verſatile. *Piſt.* Germen ſuperior, with five furrows, beaked; ſtyle central, awl-ſhaped, ſpirally furrowed, as long as the ſtamens, permanent; ſtigmas five, reflexed. *Peric.* Capſules five, aggregate, membranous, obovate, vertical, ſeparating at their inſide, ſharp-pointed at their baſe, each tipped at its ſummit with a long, linear, flat, pointed, rigid awn, hairy on its inſide, and at length ſpirally twiſted, adhering by its point to the ſummit of the ſtyle. *Seeds* one or two, erect, ovate-oblong.

Eſſ. Ch. Calyx of five leaves. Petals five. Nectariferous glands five. Barren filaments five. Fruit beaked, of five aggregate capſules, each tipped with a long ſpiral awn, bearded on the inſide.

Linnæus in his Genera Plantarum had long ago indicated a diviſion of his genus *Geranium* into ſeveral natural ſections, diſtinguiſhable by characters in their fructification and inflorescence. The late learned botaniſt Monſ. L'Heritier, purſuing the idea, divided that genus into three, each of them as naturally and diſtinctly defined as any in the whole ſyſtem, and although the convulſions of his country, and his own premature death, prevented his publiſhing an elaborate work on the ſubject, he had fortunately conferred by letter with the intelligent editors of the Hortus Kewenſis, and with the writer of the preſent article, ſo that his intention has been carried into effect, both in that work and the Flora Britannica. Of theſe three genera *Geranium* with its 10 fertile ſtamens, regular flower, and recurved naked awns, conſiſts of what are uſually called European Geraniums, bearing but one or two flowers on a ſtalk; *Pelargonium* with its ſeven fertile ſtamens, irregular flower, tubular nectary, and ſpiral bearded awns, comprehends what are generally called Cape Geraniums; while the preſent genus is made up of the Linnæan *Gerania cicutaria*.

Three ſpecies of *Erodium* are natives of Britain.

1. E. *cicutarium*. Engl. Bot. t. 1768. Hemlock Stork's-bill. (Geranium cicutarium; Linn. Sp. Pl. 951. Curt. Lond. faſc. 1. t. 51.) "Flower-ſtalks many-flowered. Leaves pinnate; leaflets ſeſſile, pinnatifid, cut." Common in waſte ground. In ſandy places near the ſea its petals are generally white, or their uſual roſe-colour is elegantly diverſied with a green ſpot on two or three of them. The *herb* is fetid, proſtrate and annual, with finely divided leaves.

2. E. *moſchatum*, Engl. Bot. t. 902. Muſky Stork's-bill. (Geranium moſchatum; Linn. Sp. Pl. 951.) "Flower-ſtalks many-flowered. Leaves pinnate; leaflets nearly ſeſſile, elliptical, unequally cut." Wild in the mountainous paſtures of Yorkſhire and Weſtmoreland, but in other places it is uſually the outcaſt of gardens, where it has often been cultivated for the ſake of the ſtrong muſky ſcent of its herbage. The *flowers* are ſmaller and leſs ornamental than thoſe of the preceding; *leaves* larger, paler, and more viſcid.

3. E. *maritimum*, Engl. Bot. t. 646. Sea Stork's-bill. (Geranium maritimum; Linn. Sp. Pl. 951.) "Flower-ſtalks barely three-flowered. Leaves heart-ſhaped, cut, crenate, rough. Stems depreſſed." Native of ſandy ſeaſhores in various places, flowering all ſummer long. When brought into a garden it becomes wonderfully luxuriant. The *root* is perennial. *Petals* white or reddiſh, for the moſt part much ſmaller than the calyx leaves.

Willdenow has 34 ſpecies of this genus in all. Moſt of them abound in the warmer countries of Europe, and the northern part of Africa, and ſeveral are cultivated with us for ornament, as *E. gruinum*, (Geranium creticum; Ger. em. 943), a hardy annual with large blue flowers; *E. hymenodes*; Andr. Repoſ. t. 413, which requires a green-houſe, and is perennial. Three ſpecies are natives of the Cape of Good Hope, *viz.* the moſt beautiful *E. incarnatum*, Ait. H. Kew. v. 2. 415. Curt. Mag. t. 261. (Geranium incarnatum; Linn. Suppl. 306.) This is a tender green-houſe plant, and therefore not very common, but worthy of all attention for the delicate hues, and eye-like pencilling, of its bloſſoms. The other two Cape ſpecies are *arduinum*, (Geranium arduinum; Linn. Sp. Pl. 952.) very little known to botaniſts, and never introduced into the gardens of Europe; and *ribifolium*, Jac. Ic. Rar. v. 3. t. 509.) an inconſpicuous flower, not much likely to excite the attention of cultivators.

ERODIUS, in *Entomology*, a genus of the Coleopterous kind, eſtabliſhed by Fabricius. Theſe inſects are generically diſtinguiſhed by the following character: the antennæ moniliform; feelers four; jaws horny, truncated, and bifid; lip horny and emarginate. This is the Fabrician definition, to which may be added that the body is roundiſh, gibbous, and emarginate; thorax tranſverſe; wing-caſes cloſely united, and longer than the abdomen.

Species.

Testudinarius. Black; wing-caſes rough, the ſides covered with whitiſh duſt. Fabr.

An inſect of large ſize, found at the Cape of Good Hope; the wing-caſes are very gibbous, with ſmall raiſed dots.

Gibbus. Black; wing-caſes with three raiſed lines. Fabr. Remarkable for the gibboſity of its form, and the obtuſity of the wing-caſes; it is of moderate ſize; and has the anterior ſhanks armed with a ſtrong tooth in the middle and at the tip. The ſpecies inhabits Arabia.

Planus. Black; wing-caſes with a ſingle raiſed line. Fabr.

Native of the ſame country as the former. The anterior ſhanks not armed with a ſpine.

Minutus. Black; wing-caſes perfectly ſmooth. Fabr. Small thorax with two impreſſed dots on the back; legs unarmed. Inhabits the eaſtern parts of the world.

Muricatus. Gibbous, black; wing-caſes muricate. Fabr.

A ſpecies deſcribed in the Fabrician Suppl. Ent. from the cabinet of Lund. It is a native of the Cape of Good Hope; in ſize and appearance reſembles E. gibbus. The head and thorax ſmooth.

EROPHEEVO, in *Geography*, a town of Ruſſia, in the government of Irkutſch; 60 miles N. of Balaganſkoi.

EROS, of ερως, *love*, in *Mythology*, one of the two chiefs over all the other cupids, being the cauſe of love. See Anteros.

EROSION, in books of *Surgery*, we often find this expreſſion uſed ſynonymouſly with the term ulceration.

Erosion, in *Geology*, according to Mr. Kirwan, (Geol. Eſſ. 230 and 285,) denotes a ſolution or melting of the ſofter calcareous particles by water, by which he accounts for the formation of the vaſt caverns and grottos to be found in the Derbyſhire lime-ſtone rocks, and thoſe of other countries. M. de Sauſſure, in his Agenda (Journal des Mines, N° 20.) directs the attention of geological travellers to the ſides of valleys (§ 12.) to ſearch for the veſtiges of the eroſion of water: by which we might underſtand a mechanical ſweeping or waſhing away of ſtrata, as well as a ſolution or melting as above.

EROSUM Folium, among *Botaniſts*. See Leaf.

EROTESIS, Ερωτησις, in *Rhetoric*, the ſame figure with *Interrogation*. Every interrogation or queſtion is not figurative; but it becomes figurative, when the ſame thing may be expreſſed in a direct manner; but the putting it by way of queſtion gives it much greater life and ſpirit. As when Cicero ſays, (in Catal. i. c. 1.) "Cataline, how long will you abuſe our patience? Do not you perceive your deſigns are diſcovered?" He might have ſaid, "You abuſe our patience a long while; you muſt be ſenſible your deſigns are diſcovered." But it is evident how much this latter mode of expreſſion falls ſhort of the force and vehemence of the former. Thus alſo, when Medea ſays, "I could ſave; and do you aſk, if I can deſtroy?" Had ſhe merely ſaid, "I could ſave, and I can deſtroy," the ſentence would have been flat, and very unfit to expreſs the rage and fury in which the poet there repreſents her. (Quint. Inſt. Orat. l. viii. c. 5.) This figure is ſuited to expreſs moſt paſſions and emotions of the mind, as anger, diſdain, fear, deſire, &c. It ſerves alſo to preſs and bear down an adverſary. This figure likewiſe diverſifies a diſcourſe, and gives it a beautiful variety, by altering the form of expreſſion, provided it be neither too frequent, nor continued too long. Beſides, the warm and eager manner in which it is expreſſed enlivens the hearers, and quickens their attention.

EROTEUM, in *Botany*, perhaps from ερωτιζω, *to queſtion*, in alluſion to its doubtful nature at firſt ſight, being very like *Thea* till the fruit is inveſtigated. Swartz. Prod. 5. The author, however, being himſelf, as it ſeems, diſſatisfied with this name, has, in his Fl. Ind. Occ. v. 1. 971, changed it to Freziera, which ſee.

EROTIA, Ερωτια, a feſtival among the Greeks, in honour of Cupid, being celebrated every fifth year with ſports and games.

EROTIANUS, in *Biography*, the author of a gloſſary, containing an explanation of all the words uſed in the writings of Hippocrates, lived in the firſt century of the Chriſtian era, in the reign of Nero, and dedicated his work to Andromachus of Crete, who was phyſician to that emperor. It was printed at Venice, in 1566, in 4to. with the notes of Barth. Euſtachius, under the title of "Vocum, quæ apud Hippocratem, collectio, et ejus operum in ſeptem ſectiones diſtributio." The gloſſary of Erotain was alſo annexed to the edition of Hippocrates, publiſhed by Foeſius at Geneva, in 1657. Haller. Bibl. Med. Eloy.

EROTIC, derived from ερως, *love*; whence ερωτικος, is applied to any thing which has a relation to the paſſion of love.

In *Medicine*, we particularly uſe the phraſe delirium eroticum, for a kind of melancholy contracted through exceſs of love.

Though, among the ſeveral ſpecies of pulſes, there be no amorous pulſe, that is, no pulſe peculiar to that paſſion; yet we can certainly diſcover where the diſorder is erotic, by the beating of the pulſe, which, in that caſe, is changeable, unequal, turbulent, and irregular. Speak to the patient of the perſon he loves, and his pulſe inſtantly changes, becoming higher and quicker; and the minute you change the converſation, the pulſe is loſt again, and is diſturbed anew.

EROTIDIA, ερωτιδια, the ſame with erotia.

EROTOMANIA, in *Medicine*, a term uſed by ſome writers to denote that modification of inſanity, of which the paſſion of love is the origin, and in which the love of a particular individual conſtitutes the predominant idea. Sauvages treats of this form of derangement under the name of *melancholia amatoria*; (ſee his Noſol. Meth. Claſs viii. Gen. xix. Spec. 2.) Sennertus under that of *amor* *inſanus*, &c. The word is derived from ἐρως, *love*, and μανια, *mania*, madneſs.

This diſeaſe is diſtinguiſhed from ſatyriaſis and nymphomania, if indeed ſuch maladies have any exiſtence, inaſmuch as the patient, ſo far from being urged by libidinous deſires, contemplates the object of his affection with reverence and diſtant admiration, as if ſhe were a divinity; he would ſpend his days in doing homage to her perfections, and deems food, ſleep, and the affairs of the world of little comparative moment. As a remedy for this ſpecies of inſanity, low and light diet has been recommended. Ovid has adviſed the performance of a long journey, during which a conſtant change of ſcene, and the abſence of all objects, with which the recollection of the individual beloved, might tend to reſtore the mind to its uſual condition: conſtant occupation of body or mind, "qui vis ſanari, res age, tutus eris;" and the admonitions of the wiſe in regard to the loſs of health, fortune, and character, which muſt attend ſuch hallucination, have alſo been ſuggeſted. The former part of the advice may be ſometimes beneficial, but thoſe who are moſt experienced in the treatment of the inſane, well know how little benefit is produced by reaſoning with madmen. See Melancholy.

EROTYLOS, in *Natural Hiſtory*, the name of a ſtone, of which we have no deſcription left us, but which the ancients are ſaid to have uſed in divination.

EROTYLUS, in *Entomology*, a genus of Coleoptera in the Fabrician ſyſtem, allied, and in ſome degree confounded, with the two Linnæan genera Chryſomela and Coccinella, and arranged by Gmelin under that of Cryptocephalus. The antennæ are filiform; feelers four and unequal, the anterior longer and hatchet-ſhaped; jaws horny and bifid; lip horny, ſhort, dilated at the lip, truncated, and ſomewhat emarginate; body ſuboval. The transformations of theſe inſects are unknown, in the perfect ſtate they are found generally on flowers. Three of the ſpecies are deſcribed by Linnæus, the remainder principally by Fabricius.

Species.

Giganteus. Oval, black; wing-caſes with numerous fulvous dots. Fabr. *Chryſomela gigantea*, Linn. *Coccinella gigantea*, Sulz. Native of India.

Cancellatus. Black; wing caſes yellow, reticulated with black. Fabr. Large and roundiſh; inhabits Brazil.

Histrio. Deep black; wing-caſes barred with black and yellow, a ſcarlet ſpot at the baſe and tip. Fabr.

A ſpecies of large ſize, an inhabitant of Cayenne.

Lugubris. Teſtaceous; antennæ and ſhanks black. Fabr. Native of America.

Gibbosus. Black; wing-caſes yellowiſh with black dots; band in the middle and at the end black. Fabr. *Chryſomela gibboſa*, Linn. *Coccinella*, Gronov.

An inſect of conſiderable magnitude, the wing-caſes of which are remarkably gibbous, and the thorax impreſſed on each ſide; it is a native of South America.

6-Fasciatus. Oval, black; wing-caſes with ſix waved fulvous bands, the anterior one interrupted. Fabr.

Inhabits Cayenne.

Notatus. Black; wing-caſes with a yellow band in the middle ſpotted with black, and marked with red at the baſe. Fabr. Native of South America.

Concatenus. Black; wing-caſes reticulated with yellow and black, and marked with two black bands. Fabr. Mant. Inſ. Country unknown; the body large.

5-Punctatus. Oval; wing-caſes black with five red dots. Fabr. Inhabits America.

Punctatissimus. Black; wing-caſes yellow with numerous black dots. Fabr.

Deſcribed from the Hunterian cabinet: an American ſpecies.

Varius. Black; wing-caſes punctured, ſpotted with fulvous in the middle. Fabr. Inhabits Surinam.

Gemmatus. Black; wing-caſes with numerous fulvous dots; thorax variolous. Fabr.

An inſect of moderate ſize, found in Cayenne.

Macrocheiros. Black; wing-caſes with alternate black and yellow bands; fore legs very long. Fabr.

Native of India.

Abdominalis. Black; wing-caſes yellow with four waved black bands and a diſtinct black dot. Fabr.

A Braſilian ſpecies, in ſize reſembling E. faſciatus, and having the abdomen yellow with two lines of black dots.

Fasciatus. Black; wing-caſes with three yellowiſh bands. Fabr.

From the Bankſian cabinet: the native place unknown: ſize moderate.

Zebra. Yellowiſh; head, baſe of the thorax, and three bands on the wing-caſes with the legs black. Fabr. Mant.

Alternans. Black; wing-caſes with two yellow bands, the anterior one dotted with black. Fabr.

Surinamensis. Black; wing-caſes red and immaculate. Fabr. Native of Surinam.

Limbatus. Oblong, black; margin of the thorax and border of the wing-caſes yellow. Fabr.

South American ſpecies; head yellowiſh with a black frontal ſpot; thorax ſmooth with a broad ſinnate lateral margin.

Nebulosus. Black; thorax, and wing-caſes varied with ferruginous. Fabr.

Inhabits the ſame country as the preceding.

Dilatatus. Oblong, black; thorax and wing-caſes ferruginous. Fabr.

Native of the Cape of Good Hope. The antennæ are brown, at the baſe ferruginous; wing-caſes ſmooth, and much broader than the body.

Morio. Oblong, black, and immaculate. Fabr.

This, and the four following ſpecies, are natives of New Holland. Theſe are deſcribed by Fabricius from the Bankſian cabinet, and are repreſented in the volume of "Donovan's General Illuſtration of Entomology, devoted to the Inſects of the Auſtralaſian regions."

Smaragdulus. Oblong, black; wing-caſes ſtriated and green.

Amethystinus. Oblong, black; thorax and wing-caſes blue; reſembles the laſt; front retuſe; wing-caſes with punctured ſtriæ.

Bicolor. Oblong, black; bronzed above.

Cupreus. Oblong, black; thorax and wing-caſes coppery.

Rufipes. Oblong, black; legs pitchy. Fabr. Mant. Inhabits Kiel.

Flavipes. Oblong, gloſſy green; antennæ and legs yellowiſh. Native of Jamaica, in the Bankſian cabinet.

EROWA, the name of a kind of nettle which grows in the mountains at Otaheite in the South Sea, with which the inhabitants make fiſhing lines, which ſerve to hold the ſtrongeſt and moſt active fiſh, and are much ſtronger than our ſilk lines of twice the thickneſs.

ERPACH, in *Geography*. See Erbach.

ERPENIUS, Thomas, in *Biography*, was born at Gorcum, in Holland, in the year 1584. His parents, natives of Bois-le-Duc, were, on account of their converſion to the Proteſtant religion, obliged to withdraw from that place, to one more favourable to the rights of private judgment. They provided their ſon with a good education in the rudiments of learning, and when they diſcovered in him a propenſity for literary purſuits they ſent him to Leyden, where he felt ſo diffident of ſucceeding in his ſtudies, that for ſome time he determined to relinquiſh them. Fortunately his deſire for knowledge overcame his modeſty, and he applied himſelf with ſo much diligence, that he obtained the higheſt praiſe of his different tutors, and excited their ſurprize at his extraordinary progreſs. He excelled in metaphyſics, but his fame with poſterity is built on the ſkill which he acquired in the oriental languages. After availing himſelf of all the advantages which the univerſity of Leyden afforded, he travelled for farther improvement in foreign countries. In England he became acquainted with Bedell, who was celebrated for his knowledge in Hebrew and rabbinical learning. In France he improved himſelf in his knowledge of the Arabic tongue; and in Italy he improved his acquaintance with the Hebrew language, by converſing with ſome learned Jews, and made himſelf maſter of the Perſian, Turkiſh, and Ethiopic tongues. After ſpending ſeveral years in foreign countries, Erpenius returned to Holland, where he was elected profeſſor of the oriental languages in the univerſity of Leyden. This was in the year 1612, and very ſhortly after his appointment he ſet up a preſs for the printing of works in the Eaſtern literature. In the year 1620 he was ſent by the States General on different journies into France, to engage Peter du Moulin, or Andrew Rivet, to undertake the theological profeſſorſhip at Leyden. After this he was appointed oriental interpreter to the States, and was employed to tranſlate the letters addreſſed to them from Aſia and Africa, and to write ſuch as were ſent by them to the ſovereigns in thoſe parts of the world. He was frequently invited into Spain by the ſovereign of that country, to explain certain inſcriptions in the Arabic language on the Mooriſh buildings and monuments in that country, and the emperor of Morocco is ſaid to have been highly pleaſed with the purity and beauty of his ſtyle, and to have exhibited his letters as objects of real curioſity. He died in the year 1624, when he was only 48 years of age. His works are numerous, and have given him a high reputation among the learned. They are enumerated by Moreri, and other biographical writers, and we are informed that he projected an edition of the Koran, with a Latin verſion and notes, likewiſe an Arabic grammar and lexicon, which his death prevented him from executing. Gerard-Jean Voſſius pronounced over him a funeral oration. Moreri.

ERPIS, or HERPIS, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana. Ptolemy.

ERRA, in *Geography*, a town of Portugal, in the province of Eſtremadura, on a river of the ſame name; 22 miles S.E. of Santarem.—Alſo, a river, which runs into the Latas, 12 miles E. of Salvateira, in the province of Eſtremadura.

ERRABARI, a town of Egypt; 10 miles N.W. of Cairo.

ERRAINE, a town of Egypt; two miles E. of Tahta.

ERRANT, in *Law*, the ſame with itinerant; the term is attributed to judges who go the circuit; and to bailiffs at large.

ERRANTS, *knight*. See KNIGHT.

ERRATA, a liſt uſually placed at the beginning or end of a book, containing the faults that have eſcaped in the impreſſion, and, ſometimes, even in the compoſition of the work.

Lindenberg has an expreſs diſſertation on typographical errors, "De Erroribus Typographycis;" in which he obſerves, that there is no book exempt from them, not even the ſacred books. He ſets himſelf to enquire into all the cauſes thereof; and propoſes means to prevent them, but he advances nothing on that article but what is either common, or impracticable.

ERRATIC, in *Aſtronomy*, an epithet applied to the planets, which are called erratic, or wandering ſtars, in contradiſtinction to the fixed ſtars.

ERRATIC *fevers*, in *Medicine*, a term uſed to expreſs ſuch fevers as, according to the language of medical writers, obſerve no regular type, that is, are not determinate either in their attacks, or in their general period. They are thus called by way of diſtinction from the typic fevers, which are regular in both. See FEVER.

ERRATIC *winds*. See WIND.

ERRHINE, in the *Materia Medica*, from εν, *in*, and ῥιν, *the noſe*, is a term applied to thoſe ſubſtances which are introduced into the noſe, for the purpoſe of exciting a diſcharge from the paſſages. When they excite ſneezing, the medicines of this claſs have been called ptarmics, and ſternutatories; and, from the diſcharge which they occaſion, they have been termed apophlegmatica, and, in barbarous Latin, caput-purgia.

Errhines, by ſtimulating the exhalent veſſels and the mucous follicles of the Schneiderian membrane, which lines the internal ſurface of the noſe, and the cavities adjoining it, excite thoſe veſſels and follicles to pour out their fluids more copiouſly than uſual. The diſcharge is ſometimes of a mucous, and ſometimes of a thinner fluid; it is often attended with ſneezing, but ſometimes is procured without. This, however, implies no difference in the operation, except as to the ſtronger or weaker irritation of the medicine employed. For although when ſneezing is excited a larger evacuation is often produced, yet the effects of errhines are not altogether proportional to the ſenſible irritation which they occaſion. See Alſton, Mat. Med. vol. i ſect. 8.

The evacuation produced by theſe medicines conſiſts not merely in emptying the mucous follicles of the lining membrane of the noſe of their contents, but in augmenting the ſecretion: whence, agreeably to the laws of the circulation, a greater afflux of fluids to thoſe parts is neceſſarily occaſioned, and therefore a diminution of the fluids in the neighbouring veſſels. In this way Dr. Cullen explains the fact, that errhines often give relief to rheumatic pains in the neighbouring parts, eſpecially to the tooth-ach, as well as to ſome forms of head-ach, pains of the ear, and ophthalmia. "How far their effects may extend," he ſays, "cannot be exactly determined; but it is probable that they may operate more or leſs on the whole veſſels of the head, as even a branch of the carotid paſſes into the noſe: and independent of this, it is not improbable that our errhines may have been of uſe in preventing apoplexy and palſy; which at leaſt is to be attended to ſo far, that whenever any approach to theſe diſeaſes is ſuſpected, the drying up of the mucous diſcharge ſhould be attended to, and, if poſſible, reſtored." Cullen's Mat. Med. vol. ii. p. 436.

The nicotiana, or tobacco, as it is commonly prepared for perſons who amuſe themſelves by ſnuffing, may be conveniently employed, with people unaccuſtomed to it, as an errhine; but repetition ſoon diminiſhes its power, and renders it uſeleſs. It produces a different degree of diſcharge in different people, even of thoſe who uſe it habitually; and Dr. Cullen ſtates, from his own experience, "that whenever the diſcharge has been conſiderable, the laying aſide ſnuffing, and therefore ſuſpending that diſcharge, may have very bad effects."

The article moſt commonly employed as an errhine, is the *Aſarum aſarabacca*, ſnuffed up the noſe every evening, for a ſhort time, in the quantity of three grains. Quincy obſerves,

ſerves, that its pungency is not immediately felt upon taking, but after ſome time it makes the noſe run very much. In larger quantities it ſometimes brings blood, and even occaſions a ſwelling of the whole head. This laſt effect, however, has been oftener produced by the *Euphorbium*, a ſtill more acrid errhine. Dr. Cullen, ſpeaking of theſe ſevere effects, ſays, "I have ſeen ſome inſtances of megrims, ophthalmias, and particularly tooth-achs, cured by the violent operation of errhines; but I never thought it ſafe to imitate the practice." The *white hellebore*, in very ſmall quantity, is alſo an acrid errhine.

ERRIFF, in *Geography*, a province of Africa, in the country of Fez. See Rif.

ERRIPSIS, from ῥιπτω, *I precipitate*, in *Medicine*, is uſed in different ſenſes, ſometimes for a weakneſs of the whole body, ſometimes only of ſome one part. When applied to the whole body, it expreſſes that utter dejection and proſtration of ſtrength which makes a man fall down like a dead carcaſs; and, when applied to the eyes, it expreſſes ſuch a debility, as renders it impoſſible to keep them open.

ERROAD, in *Geography*, a town of India, in the country of Coimbatore; 39 miles E.S.E. of Damicotta, and 48 N.E. of Coimbatore.

ERROL, a ſmall uninhabited town of America on lake Umbagog, on the north-eaſternmoſt ſettled part of Grafton county, in New Hampſhire, incorporated in 1774.

ERROMANGO, an iſland in the Southern Pacific ocean, being one of thoſe called the "New Hebrides," 18 leagues from Sandwich iſland, and 24 or 25 leagues in circuit. The middle of it lies in S. lat. 18° 54′. E. long. 169° 19′, and it is of a good height. Captain Cook anchored in a bay of this iſland; and he found that although the behaviour of the inhabitants was at firſt friendly, their real intentions were very different. They were armed with clubs, ſpears, darts, bows and arrows, and ſeemed determined to employ them in a hoſtile manner. On this account it became neceſſary for the captain to give orders to his men to fire upon the aſſailants. At length they were ſo terrified as to withdraw and make no farther appearance. Thoſe iſlanders, it was obſerved, ſeemed to be of a different race from thoſe of Mallicollo, and they ſpoke a different language. They are of a middle ſize, with a good ſhape, and tolerable features. Their colour is very dark, and their aſpect is not improved by their cuſtom of painting their faces, ſome with a black, and others with a red pigment. Their hair is curly and criſp, and ſomewhat woolly. The few women, who were ſeen and who appeared to be ugly, wore a kind of petticoat, made either of palm leaves, or of a ſimilar plant; but the men, like thoſe of Mallicollo, were almoſt entirely naked. On account of the treacherous behaviour of the inhabitants of Erromango, captain Cook called a promontory, or peninſula, near which the ſkirmiſh happened, "Traitor's Head." This is in the N.E. point of the iſland, and is ſituated in S. lat. 18° 43′, and E. long. 169° 28′.

ERRONAN, or Footoona, the moſt eaſtern iſland of all the Hebrides, appeared to captain Cook to be about five leagues in circuit, of a conſiderable height, and flat at top. On the N.E. ſide is a little peak ſeemingly disjoined from the iſle; but which was thought to be connected by low land. It is diſtant in the direction of N. by E. ½ E. 11 leagues from Port Reſolution in the iſland of Tanna.

ERROR, a miſtake of the mind in giving aſſent to a thing, or propoſition, which is not true. See Fallacy.

Some philoſophers define error an act of the mind, whereby things that ſhould be joined are ſeparated; or, things that ſhould be ſeparated, are joined; or a wrong judgment, diſagreeing with the things whereon it is paſſed.

Error ſtands in oppoſition to truth, which conſiſts in an agreement between the propoſition and the thing whereof it is affirmed or denied.

However, a bare failure, or non-attainment of truth, does not conſtitute error; that being common both to ignorance and doubting.

Error only ſtands diſtinguiſhed from *falſhood*, in that the former is in the mind, and the latter only in the propoſition.

The great origin of all error, *i. e.* of believing that to be true which is falſe, is a liberty, or power, in the human mind, of giving its aſſent to ideas, to propoſitions, that are obſcure, as if they were perſpicuous and plain.

Particular cauſes of error are, inadvertency, ignorance, impatience, intereſt, authority, education, &c. See Faith, Probability, Opinion.

Againſt all which, there is this one general rule or caution laid down by F. Malebranche and others; *viz.* never to give our full aſſent to any propoſition, unleſs the evidence for it be ſo ſtrong, as that we can no longer withhold it, without incurring the ſecret reproaches of our own reaſon.

Mr. Locke reduces the cauſes of all our errors to theſe four; *viz.* 1. Want of proofs. 2. Want of ability to uſe them. 3. Want of will to uſe them. And, 4. Wrong meaſures of probability.

F. Malebranche conſiders five occaſional cauſes of error, or rather of five different kinds of errors, accommodated to the different manners we have of perceiving things. 1. Errors of ſenſe. 2. Of the imagination. 3. Of the underſtanding. 4. Of our inclinations. And, 5. Of the paſſions. See Sense, Imagination, Understanding, Inclination, and Passion.

Errors, *popular*. See Popular.

Error, in *Law*, generally denotes a fault, or overſight, either in pleading, or in proceſs; upon either of which is brought a writ, by way of remedy, called a *writ of error*; in Latin, *de errore corrigendo*.

A writ of error lies for ſome ſuppoſed miſtake in the proceedings of a court of record; for, to amend errors in a baſe court, not of record, a writ of "falſe judgment" lies. The writ of error only lies upon matter of law ariſing upon the face of the proceedings; ſo that no evidence is required to ſubſtantiate or ſupport it; there being no method of reverſing an error in the determination of *facts*, but by an attaint, or a new trial, to correct the miſtakes of the former verdict. A writ of error may be brought for notorious miſtakes in the judgment or other parts of the record; as where a man is found guilty of perjury, and receives the judgment of felony, or for other leſs palpable errors, ſuch as any irregularity, omiſſion, or want of form in the proceſs of outlawry, or proclamations; the want of a proper *addition* to the defendant's name, according to the ſtatute of additions; for not properly naming the ſheriff, or other officer of the court, or not duly deſcribing where his county or court was held; for laying an offence committed in the time of the late king, to be done againſt the peace of the preſent; and for many other ſimilar cauſes, which (though allowed out of tenderneſs to life and liberty) are not much to the credit or advancement of the national juſtice. Theſe writs of error to reverſe judgments in caſe of miſdemeanors are not to be allowed of courſe, but on ſufficient probable cauſe ſhewn to the attorney-general; and then they are underſtood to be grantable of common right, and "ex debito juſtitiæ." But writs of error to reverſe attainders in capital caſes are only allowed "ex gratia;" and not without expreſs warrant under the king's ſign manual, or at leaſt by the conſent of the attorney general. 1 Vern. 170. 175.

If a writ of error be brought to reverſe any judgment of an inferior court of record, where the damages are leſs than ten pounds; or, if it is brought to reverſe the judgment of any ſuperior court after verdict, he that brings the writ, or that is plaintiff in error, muſt (except in ſome peculiar caſes) find ſubſtantial pledges of proſecution, or bail (ſtat. 3 Jac. I. c. 8. 13 Car. II. c. 2. 16 and 17 Car. II. c. 8. 19 Geo. III. c. 70.): to prevent delays by frivolous pretences to appeal; and for ſecuring payment of coſts and damages, which are now payable by the vanquiſhed party in all, except a few particular inſtances, by virtue of the ſeveral ſtatutes here recited. 3 Hen. VII. c. 10. 13 Car. II. c. 2. 8 and 9 W. III. c. 11. 4 and 5 Ann. c. 16.

A writ of error lies from the inferior courts of record in England into the king's bench, and not into the common-pleas. (Finch. L. 480. Dyer 250.) Alſo from the king's bench in Ireland to the king's bench in England. It likewiſe may be brought from the common pleas at Weſtminſter to the king's bench; and then from the king's bench the cauſe is removable to the houſe of lords. From proceedings on the law ſide of the exchequer a writ of error lies into the court of exchequer chamber, before the lord chancellor, lord treaſurer, and the judges of the court of king's bench and common pleas; and from thence it lies to the houſe of peers. From proceedings in the king's bench in debt, detinue, covenant, account, caſe, ejectment, or treſpaſs, originally begun there by bill (except when the king is party) it lies to the exchequer chamber, before the juſtices of the common pleas, and barons of the exchequer; and from thence alſo to the houſe of lords (ſtat. 27 Eliz. c. 8.); but when the proceedings in the king's bench do not firſt commence therein by bill, but by original writ ſued out of chancery, this takes the caſe out of the general rule laid down by the ſtatute (1 Roll. Rep. 264. 1 Sid. 424. 1 Saund. 346. Carth. 180. Comb. 295.); ſo that the writ of error then lies, without any intermediate ſtage of appeal, directly to the houſe of lords, the dernier reſort for the ultimate deciſion of every civil action. Each court of appeal, in their reſpective ſtages, may, upon hearing the matter of law in which the error is aſſigned, reverſe or affirm the judgment of the inferior courts; but none of them are final, ſave only the houſe of peers, to whoſe judicial deciſions all other tribunals muſt therefore ſubmit, and conform their own. Blackſt. Com. book iii.

Error, *to aſſign.* See Assign.

Errors, *Clerk of the.* See Clerk.

Error *loci*, literally *error of place*, a doctrine of conſiderable importance in the theory of diſeaſes, taught by the celebrated Boerhaave. It was deemed the principal cauſe of thoſe obſtructions to the circulation of the blood, on which inflammation, in all its varieties, was ſuppoſed to depend. "The parts of a fluid," ſays Boerhaave, "become unable to paſs by error of place (per errorem loci), when a corpuſcle ruſhes into the dilated mouth at the baſis of a conical canal, and cannot paſs through the narrow end of it." (Aphoriſm 118.) This doctrine is founded upon theſe three circumſtances; the ſeries of particles, of which the blood is compoſed; the ſeries of progreſſively diminiſhing veſſels; and the conical form of theſe veſſels: and it is thus explained by the comment of Van Swieten.

The largeſt particles in the blood are the red globules, which are to be found naturally in the larger veſſels only. Now the extremities of the arteries carrying red blood, tranſmit the red globules ſingly, according to the obſervations made with microſcopes on the pellucid parts of living animals. The finer parts of the blood are conveyed into the ſmaller lateral veſſels, and the red vein receives the red blood only. The veſſel of the next magnitude receives all the fluids except the red globules, and retaining the larger particles only, (*viz.* the ſerous globules) tranſmits the remaining thinner liquids into the ſtill ſmaller veſſels, that ariſe from the ſerous artery. This law obtains, then, in all the decreaſing ſeries of veſſels. The red arteries can receive and tranſmit all the humours; the ſerous arteries exclude the red part of the blood, but tranſmit the ſerous globules, and every other thinner fluid, and ſo on. Now, ſhould the diameter of a lateral veſſel ariſing from a larger one be by any means increaſed, for example, the aperture of a ſerous artery, which ariſes from a red one, a red globule might be able to enter its orifice when thus dilated; but as a conical canal always grows narrower, it will ſhortly ſtick faſt, and be by no means able to paſs through its extremity, and conſequently will cauſe an obſtruction, as the bulk of the particle to be carried through exceeds the capacity of the tranſmitting veſſel.

This error loci of the fluids was conſidered as the proximate cauſe of inflammation by Boerhaave, and his commentator illuſtrates the dilatation and diſtention of the lymphatic and ſerous veſſels by the red blood in the caſe of inflammations of the eye; in which the veſſels of the ſurface of the eye, which are naturally tranſparent, become red, and viſible, ſometimes even giving a red colour to the whole of the ſurface. See Van Swieten, Comment. ad Aph. 118—378, &c.

ERRUCA, in *Ancient Geography*, a town of Italy, belonging to the Volſii, according to Diodorus Siculus.

ERSE, in *Geography*, a river of Germany, in the circle of Lower Saxony, which runs into the Fuhſe; 8 miles S. of Zelle.

ERSH, in *Agriculture*, is a term ſignifying land in the ſtate of ſtubble after the grain has been taken off. Hence we have pea, bean, and different ſorts of grain erſhes.

Ersh-*Crop*, is ſuch a crop as is grown after ſome of theſe ſorts of ſtubbles have been turned down by the plough.

ERSTEIN, in *Geography*, a ſmall town of France, in the department of the Lower Rhine, chief place of a canton in the diſtrict of Barr, with a population of 2344 individuals. The canton contains 14 communes and 8991 inhabitants, on a territorial extent of 137½ kiliometres.

ERTA, a town of Aſia, in Parthia.

ERTHOLM, a ſmall iſland, about three leagues from the coaſt of Schoonem, and half a league from Bornholm. It belongs to the Danes; and till of late was garriſoned only with 50 men: the force has been ſince augmented to 500. This iſland may be eaſily captured and retained by that power, which, during the interval of naval operations in the Baltic, has the ſuperior fleet.

ERTO del Ferro, a town of Italy, in the kingdom of Naples, and province of Calabria Citra; 10 miles W. of Umbriatico.

ERTZGEBIRGE, or rather Ertzgeburge, (arch-mountainous country,) is the fifth of the ſeven circles into which that part of the kingdom of Saxony, which is called Saxony Proper, or formerly Electoral Saxony, is divided. As late as the tenth century this whole extenſive tract of mountainous country was nothing but an impervious foreſt, called Miriquido, or Miriquidvi, few ſpots of which began to be cleared in 1004. It is bounded to the north by the circles of Miſnia, or Meiſſen and Leipzick, and by the principality of Altenburg, to the weſt by the ſame principality, the circles of Neuſtadt and Voigtland, and the dominions of the princes of Reuſs; to the ſouth and eaſt by the kingdom of Bohemia. Its principal rivers are the Zſchopau, the Flöhe, the Pöhl, the Preſaitz, and the Schwartzwaſſer.

The territorial extent of the Ertzgebirge is 121 German ſquare miles, and its population, in 1785, amounted to 405,600 individuals, which gives $3352\frac{1}{15}$ inhabitants to the German ſquare mile. It produces corn, potatoes, vegetables of all ſorts, and excellent flax, and has ſeveral manufactories, but chiefly thoſe which work upon minerals and metals.

The circle of the Ertzgebirge is remarkable for its numerous and valuable mines, which, in 1789, employed 12,867 miners, and, in 1788, yielded in ſilver only 50,618 marks. The aggregate of all the metals produced the ſum of 700,640 dollars. Amalgamation, or application of mercury to extract the ſilver from the ore, was firſt introduced in the Saxon mines in the year 1787.

Freyberg is the chief place of the Ertzgebirge, and the firſt town in Europe for the ſtudy of mineralogy. See Freyberg.

The whole circle of the Ertzgebirge contains 61 towns and 723 villages. It is ſubdivided into 13 diſtricts, *viz.* Freyberg, Auguſtuſburg, Chemnitz, Roſſen, Frauenſtein, Altenberg, Lauterſtein, Wolkenſtein, Annaberg, Grünhayn, Schwartzenberg, Weiſenburg, and Zwickau.

ERTZICA, a town of Aſia Minor, in Cappadocia, commonly called *Arzingham*.

ERUBRUS, a river of Gaul, thought by M. D'Anville to be the Rouver, which runs into the Moſelle, a little below Treves.

ERUCA, in *Zoology*. See Caterpillar.

Eruca *marina griſeo fuſca*. See Aphrodita.

ERUCAGO, in *Botany*, Tourn. Inſt. 232. t. 103, ſee Bunias, ſpec. 3.

ERUCTATION, Belching, the ſame as ructation.

ERUDITION, denotes learning or knowledge; and chiefly that of hiſtory and antiquity, of languages and of books, which is the reſult of hard ſtudy, and extenſive reading. The Scaligers were men of deep erudition: the writings of M. Launoy, a prieſt of the Oratory, are full of erudition.

Mr. Locke ſays, it is of more uſe to fill the head with reflections than with points of erudition. If the mind be not juſt and right, ignorance is better than erudition, which only produces confuſion and obſcurity. M. Balzac calls a heap of ill choſen erudition the luggage of antiquity.

ERVEDEIRA, in *Geography*, a town of Portugal, in the province of Eſtremadura; 12 miles N.N.W. of Leiria.

ERVILIA, in *Botany*, an ancient name for a kind of vetch or pea. See Pisum Ochrus, alſo Ervum.

ERUPA, in *Ancient Geography*, a town of Arabia Deſerta. Ptolemy.

ERUPTION, in general, a burſting forth, or excluſion of ſomething which was before covered, or concealed.

The eruption of volcanos, or burning mountains, is frequently the effect and iſſue of earthquakes. See Earthquake, Volcano, &c. For an account of the eruptions of mount Ætna and Veſuvius, ſee Ætna and Vesuvius.

Eruption, in *Medicine*, denotes the appearance of various ſpots and diſcolourations of the ſkin, whether puſtules, pimples, raſhes, &c.: thus, we ſpeak of an eruption of ſmall-pox, or of meaſles; and, by a figure of ſpeech, theſe puſtules, raſhes, &c. are often denominated eruptions, or cutaneous eruptions.

Eruption *in Infants*. See Infants.

ERUPTIVE Diseases, a term nearly ſynonymous with Cutaneous *Diſeaſes*, (which ſee). Eruptive fevers are thoſe febrile diſeaſes which are accompanied by an eruption of ſpots or tumours on the ſkin, by which they are principally characterized: ſuch as ſmall-pox, meaſles, chicken-pox, cow-pox, ſcarlet fever, eryſipelas, ſhingles, &c.

ERVUM, in *Botany*, an ancient Latin name of unknown derivation. Tare. Linn. Gen. 376. Schreb. 498. Willd. Sp. Pl. v. 3. 1112. Sm. Fl. Brit. 775. Juſſ. 360. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, erect, cloven half-way down into five acute ſegments, all of equal breadth, but the lowermoſt is rather the longeſt. *Cor.* papilionaceous, twice as long as the calyx: ſtandard obovate, nearly entire, aſcending, with a broad claw, compreſſed and keeled at the back; wings two, oblong, obtuſe, half heart-ſhaped, ſhorter than the ſtandard, with narrow claws; keel as long as the wings, of two conjoined compreſſed petals, with ſeparate claws. *Stam.* Filaments in two ſets, one compoſed of nine, the other ſolitary; anthers roundiſh, two-lobed, erect. *Piſt.* Germen ſuperior, oblong, compreſſed, horizontal; ſtyle ſimple, aſcending, forming a right angle with the germen, and about half as long; ſtigma capitate, obtuſe, hairy all over. *Peric.* Legume oblong, obtuſe, compreſſed, rigid, knotty from the prominent ſeeds, of one cell, and two pointed, ſpirally-elaſtic valves. *Seeds* from two to four, occaſionally more, roundiſh, ſomewhat compreſſed.

Eſſ. Ch. Stigma capitate, hairy all over.

The genus *Ervum* in Linnæus is a heterogeneous aſſemblage, difficult to be accounted for. *E. Lens*, the ſpecies from which his generic character ſeems to have been principally taken, is moſt completely a *Cicer*, under which head it ſhould have been deſcribed in our eighth volume. *E. ſolonienſe* is not only a true *Vicia*, but the very ſame plant with *Vicia lathyroides*, Linn. Sp. Pl. 1040. See Engl. Bot. t. 30. *E. monanthos* and *Ervilia*, having the ſtyle hairy on the upper ſide, appear to us to belong to *Lathyrus*. Thus none of the Linnæan *Erva* remain, except our two Britiſh ſpecies, and theſe are not only very peculiar in habit, but according to the analogy of the tribe to which they belong, their ſtigma affords an excellent eſſential character, not to be found in any other *diadelphous* flower. All this was firſt explained in the Flora Britannica, by the author of the preſent article, and Willdenow has adopted it in every point, except that he retains the old erroneous character, "calyx deeply five-cleft," in addition to that derived from the ſtigma, and alſo makes *E. Ervilia* a *Vicia*. He moreover adopts a ſuppoſed new ſpecies from Desfontaines, making three in all.

1. E. *tetraſpermum*. Smooth-podded Tare. Linn. Sp. Pl. 1039. Curt. Lond. faſc. 1. t. 55. Engl. Bot. t. 1223. Stalks moſtly two-flowered. Pods ſmooth, many-ſeeded.—A troubleſome weed in cultivated land throughout Europe, flowering in June and July. *Root* annual, fibrous. *Stem* weak, climbing, branched, ſquare, hairy. *Leaflets* numerous, alternate, linear-oblong, obtuſe, hairy beneath, their common ſtalk ending in a branched tendril. *Flower-ſtalks* axillary, ſolitary, ſlender, as long as the leaves without their tendril, each bearing two (ſometimes ſolitary,) little drooping flowers of a pale blue veined with dark purple. *Calyx* hairy. *Pods* half an inch long, pendulous, oblong or obovate, ſmooth. *Seeds* four; occaſionally from five to ſeven in a variety found in Huntingdonſhire and at Algiers, which we have in vain tried to make a diſtinct ſpecies.

2. E. *vicioides*. Vetch-like Tare. Desfont. Atlant. v. 2. 168. t. 198. Willd. Sp. Pl. v. 3. 1112.—Stalks many-flowered. Pods ſilky, two-ſeeded. Leaflets obovate, entire. Gathered by Desfontaines in hedges at Algiers. It appears to be very nearly related to the following, from which it

chiefly differs in being rather larger, and in having more rounded and not emarginate *leaflets*. Nothing however is more variable than the termination of the leaflets in *Vicia* and its allies. The *pods* are called ſilky, which is perhaps equally applicable to *E. hirſutum*. All things conſidered, we much doubt of the permanency of this ſpecies, which we, like Willdenow, adopt entirely from the excellent work of Desfontaines. We tolerate, but cannot approve the mixture of Greek and Latin in the name *vicioides*, which if the ſpecies ſhould remain, ought to be made *viciæformis*.

3. E. *hirſutum*. Hairy-podded Tare. Linn. Sp. Pl. 1039. Curt. Lond. faſc. 1. t. 54. Engl. Bot. t. 970.—Stalks many-flowered. Pods hairy, two-ſeeded. Leaflets emarginate.—A pernicious weed in cornfields and paſtures throughout Europe. It much reſembles the firſt ſpecies, but the *ſtem* is uſually ſmoother, the ends of the *leaflets* more abrupt and notched, the *flowers* and *pods* more numerous on each ſtalk. The moſt eſſential difference conſiſts in the ſhorter, ſomewhat rhomboid, hairy *pods*, with only two ſeeds.—Mr. Curtis obſerves that he has "in wet ſeaſons ſeen whole fields of corn overpowered and totally deſtroyed by this plant, which is ſtronger and more prolific than *E. tetraſpermum*." He does not, however, ſuggeſt any remedy. Theſe weeds are too minute and inconſpicuous when young to be eradicated, and when they have fixed their tendrils upon the crop, they can no longer be ſeparated without "rooting up alſo the wheat with them." S.

Ervum *Orientale*. See Sophora.

ERVY, in *Geography*, a ſmall town of France, in the department of the Aube, chief place of a canton in the diſtrict of Troyes, with a population of 1975 individuals. It is 9 miles S. of St. Florentin, and has ſome manufactures of linen-cloth. The canton contains 14 communes and 11,199 inhabitants, on a territorial extent of 222½ kilometres.

ERWASH, a river of England, which riſes in the county of Nottingham, and almoſt in its whole courſe ſeparates that county from Derbyſhire, and falls into the Trent, 4 miles S. W. of Nottingham. See Erewash.

ERWITE, a town of Germany, in the circle of the Lower Rhine, and duchy of Weſtphalia; 5 miles S. of Lippſtadt.

ERXLEBEN, John Christian Polycarp, in *Biography*, was born in June, 1744, at Quedlingburg, where his father was dean of St. Nicholas's church. He ſtudied medicine at Gottingen, where he took the degree of maſter of arts in 1765, and ſhortly after gave lectures on natural hiſtory and the veterinary ſcience. Having publiſhed his introductory lectures, he undertook, at the expence of the Hanoverian government, a tour through France, Holland, Denmark, and a great part of Germany, in the courſe of which he acquired much practical knowledge in the veterinary art. On his return he lectured on the ſeveral ſciences connected with natural hiſtory, and natural and experimental philoſophy. In 1774, and the following years, he was elected a member of moſt of the learned ſocieties on the continent. He died in Auguſt, 1777, when he had but juſt attained his thirty-third year. Erxleben publiſhed many works which were highly eſteemed, among theſe are "Principles of Natural Hiſtory;" "Principles of Natural Philoſophy;" "An Introduction to the Veterinary Art." Gen. Biog.

ERYANNOS, in *Ancient Geography*, a river of Aſia Minor, in the Troade, which had its ſource in mount Ida.

ERYBIUM, a town of Greece, in the Doride, ſituated, according to Diodorus Siculus, at the foot of mount Parnaſſus.

ERYCEIRA, Francis de Meneses, *Count of*, in *Biography*, born at Liſbon in 1614, was brought up to the uſe of arms, and obtained ſome important offices under government; but in the midſt of his uſual occupations he cultivated literature, and publiſhed a number of works, particularly hiſtories of Tangier and Portugal; and the life of John I. king of Portugal.

Eryceira, Francis-Xavier de Meneses, was grandſon of the preceding, and, like him, united a literary with an active and military life. He was born at Liſbon in 1672, and roſe to eminence in the ſtate. He was choſen member of various learned ſocieties. From his anceſtor he inherited a well choſen and extenſive library, to which he made many great additions. He is ſaid to have been the author of more than a hundred different works, of theſe, however, but few ſeem entitled to notice. The beſt known are, "Memoirs on the Value of the Monies of Portugal," 4to. 1738; "Reflection on Academical Studies;" "Parallels on Illuſtrious Men and Women;" and "A Tranſlation of the Henriade." He died in the year 1743. Nouv. Dict. Hiſt.

ERYCINA, in *Mythology*, a ſurname given to Venus, from Erix, a mountain in Sicily, where ſhe had a temple. Venus Erycina had alſo a temple at Rome, which was deemed very ancient even in the time of Thucydides. See Erix.

ERYMANTHUS, in *Ancient Geography*, a mountain or foreſt of the Peloponneſus, in Arcadia, E. of a river of the ſame name, which had its ſource towards the north, on the confines of the Elide and of Arcadia, in mount Lampie. The wood of Erymanthus was full of boars, which made great deſolation in the country. Hercules was employed to give chaſe to them, which he did with ſuch ſucceſs, that he flew with his own hands the largeſt of them. See Hercules.—Alſo, a town of the Peloponneſus, in Arcadia, called *Phegia* and *Pſophis*, according to Pauſanias.

ERYMI, a people of Scythia, on this ſide of the Imaus. Ptolemy.

ERYMNÆ, a town of Aſia Minor, in Lycia. Steph. Byz.—Alſo, a town of Greece, in Theſſaly; placed by Pliny in Magneſia.

ERYNGIUM, in *Botany*, ἠρυγγιον of Dioſcorides, the derivation of which is unknown. Eryngo or Sea Holly. Linn. Gen. 127. Schreb. 177. Willd. Sp. Pl. v. 1. 1356. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 288. Juſſ. 226. Gærtn. t. 20. Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbelliferæ*.

Gen. Ch. *Common Receptacle* conical. *Flowers* all fertile, ſeſſile, with ſcales between them. *Involucrum* of the whole receptacle of many leaves, flat, ſpreading beyond the flowers. *Cal.* Perianth ſuperior, of five upright, acute leaves, ſeſſile on the germen, ſhorter than the corolla. *Cor.* in the aggregate uniform, roundiſh. Petals five, equal, oblong, with a linear longitudinal ſtricture, their points bent in, ſo as nearly to reach the baſe. *Stam.* Filaments five, capillary, ſtraight, projecting far above the corolla; anthers oblong, verſatile. *Piſt.* Germen inferior, briſtly; ſtyles two, thread-ſhaped, a little ſpreading, ſomewhat ſhorter than the filaments; ſtigmas ſimple. *Peric.* Fruit ovate, ſeparable perpendicularly into two parts. *Seeds* oblong, cylindrical; in ſome ſpecies remaining ſhut up in the cruſt of the pericarp, in others deciduous from it.

Eſſ. Ch. Involucrum of many leaves. Flowers in little denſe heads. Common receptacle conical, ſcaly. Seeds briſtly.

A moſt ſingular and very natural genus, having the habit and aſpect of a thiſtle, the herbage rigid, thorny, either more or leſs tinged with vivid blue, or pallid and whitiſh; while the fructification is exactly that of an umbelliferous plant, though the infloreſcence is capitate. Willdenow has eleven ſpecies, but they and their ſynonyms require a thorough inveſtigation. Two are natives of Britain, *viz. E. maritimum*, Engl. Bot. t. 718, (in which plate we are ſorry to remark that the petals are drawn reflexed inſtead of inflexed, an error that till now eſcaped us.)—This is frequent on ſandy ſea ſhores throughout Europe, flowering in July and Auguſt. The long creeping perennial *roots* are aromatic and ſomewhat acrid; they are eſteemed ſtimulant and reſtorative, and are ſometimes ſold candied. The herbage is glaucous variegated with a permanent blue. *Leaves* rounded, plaited, lobed, with ſpinous teeth. *Flowers* blue, in denſe terminal heads, encompaſſed with a large leafy involucrum. *Scales* of the receptacle three-cleft. The other Britiſh ſpecies is *E. campeſtre*, Engl. Bot. t. 57, found very rarely in England, though common on the continent. Its *leaves* are much more narrowly divided than the firſt, and pinnatifid. *Flowers* greeniſh-white, with narrow involucral leaves and undivided ſcales. This appears to be the true ηρυγγιον of Dioſcorides.

Among the exotic kinds *E. amethyſtinum*, Linn. Sp. Pl. 337, a native of Styria; *E. alpinum*, ibid. Curt. Mag. t. 922, from the Swiſs alps; and *E. planum*, Jacq. Auſtr. t. 391; are all hardy perennials, frequently cultivated for ornament. The *alpinum* is indeed peculiarly handſome, on account of its many-leaved, finely divided, blue involucrum.

The following five ſpecies are not in Willdenow.

E. *cyaneum*. Sm. Prod. Fl. Græc. Sibth. v. 1. 175. Fl. Græc. v. 3. t. 258. unpubliſhed. "Radical leaves in five deep pinnatifid ſegments. Stem much branched and divaricated. Involucrum of about five leaves."—Common in Greece and the iſlands of the Archipelago. The *root* is perennial *Stem* 12 or 18 inches high, of a fine blue, as well as the involucrums and foliage, many-flowered and divaricated. *Leaves* ſmall, in linear, narrow, pinnatifid ſegments. Heads of *flowers* ſmall, blue, with prominent, conſpicuous, white anthers. This moſt reſembles *E. triquetrum*, Vahl. Symb. v. 2. 46, in habit, but the flowers and involucrum are very different.

E. *multifidum*, ibid. Fl. Græc. v. 3. t. 259.—"Leaves doubly pinnatifid, ſomewhat lyrate; radiated at the extremity. Stem corymboſe. Involucrum pinnatifid."—Gathered by Dr. Sibthorp in the Morea. Taller than the laſt, with a bright blue *ſtem* and *flowers*. The finely pinnatifid *leaves* give it the aſpect of an *Echinops*. This is preſumed to be Eryngium creticum erectum, folio multifido, caule et ramis amethyſtinis; Tourn. Cor. 23.

E. *parviflorum*, ibid. (E. foliis laciniatis, capitulis florum exiguis et denſe congeſtis; Tourn. Cor. 23.) "Leaves bipinnatifid. Stem corymboſe. Involucrum three-cleft or ſimple, four times as long as the head." Of this no figure is extant, nor is it known where Dr. Sibthorp gathered the ſpecimens found in his herbarium. The *root* is perennial. *Herb* whitiſh. *Stem* denſely clothed with leaves, and bearing numerous flowers at the ſummit. *Leaves* twice or thrice pinnatifid, their ſegments narrow and divaricated. Heads of *flowers* very ſmall, with large involucra, generally of five leaves, which are either undivided or three-cleft.

E. *purpuratum*. Leaves all pinnatifid, their lower part fringed with capillary teeth. Stem nearly ſimple, with few flowers. Involucrum of about ſeven undivided leaves.—Gathered near Tangier by the late M. Brouſſonet and the Abbé Durand, who ſeverally ſent ſpecimens to Dr. Smith. *Root* perennial. *Stems* a ſpan high, round, furrowed, leafy, ſcarcely branched, but bearing about three dark-blue heads of *flowers*, with very ſpinous calyces. *Leaves* all nearly alike, pinnatifid, with decurrent, ſometimes lobed, ſegments; their lower part claſping the ſtem, pectinated, fringed with fine long capillary teeth. Great part of the ſtem, and the upper ſide of each leaf of the involucrum, are tinged with a rich deep blueiſh purple, hardly equalled in any other of the genus.

E. *carthamoides*. Leaves oblong, toothed, undivided, heart-ſhaped and claſping the ſtem at their baſe. Stem nearly ſimple, with few flowers. Involucrum of ſeveral ovate leaves. Gathered by M. Brouſſonet in the neighbourhood of Algiers, flowering in June. *Stem* a foot high, ſtrong, round, leafy, ſometimes purpliſh, ſimple, except at the ſummit, where it bears from three to five large heads of blueiſh *flowers*, whoſe involucrum conſiſts of ſeveral large, ovate, purpliſh, ſpinous-toothed leaves, much reſembling thoſe of a *Carthamus*. The radical and ſtem-*leaves* are all ſimple, oblong, wavy, with large ſpinous teeth, veiny and pale-green.

ERYNGO, in the *Materia Medica*. The root of eryngium is attenuant and deobſtruent, and is therefore eſteemed a good hepatic, uterine, and nephritic. Its whole virtue, it is to be obſerved, conſiſts in the external or cortical part. Their virtues, however, appear to be but weak; and they are now ſcarcely otherwiſe uſed than as made into a ſweetmeat.

The London college directs it to be candied in the following manner: boil the roots till the rind will eaſily peel off; when peeled, ſlice them through the middle, and the pith being taken out, waſh them three or four times in cold water; then for every pound of roots thus prepared, take two pounds of double-refined ſugar; diſſolve the ſugar in water, ſet it on a fire, and as ſoon as it begins to boil, put in the roots, and continue the boiling till they become ſoft.

Theſe candied roots are an ingredient in artificial aſſes milk, which is thus made: take of candied eryngo root one ounce, pearl barley half an ounce, liquorice root three drams; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil them gently together, then ſtrain the liquor for uſe, of which half a pint ſhould be drunk three times a day.

ERYNNIS, *q. d.* ερις νȣ, *contentio mentis*, or becauſe, as Pauſanias remarks, ερινευειν ſignifies to fall into a fury, or *Furious*, a name given to Ceres by the Sicilians.

ERYSIBE, in *Botany*, ερυσιβη, *ruſt, or the mildew of corn*, from its ruſty panicle. Roxb. Pl. Coromand. v. 2. 31. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Sapotæ*, Juſſ.

Gen. Ch. *Cal.* Perianth in five deep, roundiſh, concave, permanent ſegments. *Cor.* of one petal, ſalver-ſhaped, the length of the calyx; tube cylindrical, pervious; limb the length of the tube, in 10 roundiſh ſegments, ſpreading. *Stam.* Filaments five, very ſhort, inſerted into the lower part of the tube; anthers erect, ovate, ſhorter than the tube. *Piſt.* Germen ſuperior, ovate; ſtyle none; ſtigma five-lobed. *Peric.* Berry oval, of one cell. *Seed* ſolitary, large.

Eſſ. Ch. Corolla ſalver-ſhaped; limb in ten equal ſegments. Style none. Stigma five-cleft. Berry ſuperior, with one ſeed.

E. *paniculata*. Roxb. Coromand. t. 159. The only known ſpecies, a native of the mountain foreſts of India, from whence Dr. Roxburgh ſent us ſpecimens in 1789. A very large climbing ſhrub. *Branches* alternate, leafy, round, clothed when young with copious ruſty down. *Leaves* alternate, three or four inches long, ſpreading and deflexed, elliptic-oblong, pointed, entire, veiny; ſmooth and ſhining above; paler and opaque beneath. *Footſtalks* half an inch long, angular, ruſty. *Stipulas* none. *Panicles* many-flowered, terminal, erect, much branched, about a ſpan long, their ſtalks, ſmall oblong ſcattered bracteas, and the calyx, all denſely clothed with ruſty down. Tube of the *corolla* greeniſh; limb yellow, about three lines in diameter. *Berry* the ſize of a ſmall cherry, black, pulpy, containing one large ſeed.

Of the uſes or qualities of this plant or its fruit we have no account. From its botanical affinity to *Chryſophyllum*, *Achras*, &c. it may certainly be eaten with ſafety. The flowers are not inelegant.

ERYSIMA, in *Ancient Geography*, a town of Aſia, in Cappadocia.

ERYSIMUM, in *Botany*, ερυσιμον of Theophraſtus and Dioſcorides, about the etymology of which there is much controverſy among the learned, but, as often happens in ſuch controverſies, nothing ſatisfactory. Hedge-muſtard. Linn. Gen. 339. Schreb. 442. Willd. Sp. Pl. v. 3. 509. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 706. Juſſ. 239. Tournef. t. 111. Gærtn. t. 143. Claſs and order, *Tetradynamia Siliquoſa*. Nat. Ord. *Siliquoſæ*, Linn. *Cruciferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of four ovate-oblong, coloured, parallel, cohering, deciduous leaves. *Cor.* cruciform, of four oblong, flat, very obtuſe petals, whoſe claws are the length of the calyx and erect. Nectary a gland betwixt each of the ſhorter filaments and the germen. *Stam.* Filaments ſix, the length of the calyx; of which two oppoſite ones are ſhorter than the reſt; anthers ſimple. *Piſt.* Germen ſuperior, linear, ſquare, the length of the ſtamens; ſtyle very ſhort; ſtigma ſmall, capitate, permanent. *Peric.* Pod long, linear, ſtraight, exactly ſquare, of two cells and two valves. *Seeds* numerous, ſmall, roundiſh.

Eſſ. Ch. Pod ſtraight, columnar, exactly ſquare. Calyx-leaves cohering. Stigma capitate.

Willdenow has 14 ſpecies, of which five are Britiſh.

1. E. *officinale.* Linn. Sp. Pl. 922. Curt. Lond. faſc. 5. t. 50. Engl. Bot. t. 735. "Pods cloſe-preſſed to the main ſtalk. Leaves runcinate." Common in waſte ground and about hedges. This is uſually taken for the ερυσιμον of Dioſcorides, whoſe deſcription, more full than uſual with that writer, is very applicable to it. Dr. Sibthorp, however, decidedly conſidered *Siſymbium polyceratium* as the plant Dioſcorides meant, and this, perhaps, will be found to accord ſtill better with his deſcription, which compares the horn-like pods to fænugreek. See its figure in Matthiolus, Ed. Valgr. fol. v. 1. 524. The ερυσιμον of Theophraſtus is ſuppoſed to be a ſtill different plant, as he reckons it among the various kinds of grain.

In this and ſimilar caſes, therefore, though the Linnæan generic name is adopted from ancient writers, it does not follow that their plant is of the ſame genus, which matter is frequently impoſſible to be aſcertained. It is ſufficient that ſuch names are eſtabliſhed by common conſent amongſt ſyſtematical botaniſts, from whom they acquire a new ſtamp of authority; nor ought they to be changed, whatever new light may be thrown upon them by future commentators. We ſtudy by the arrangements of Linnæus or Juſſieu, not by thoſe of Theophraſtus or Dioſcorides. It is only in caſe any ſpecies requires to be ſeparated from an eſtabliſhed genus, that we are glad to recur to its ancient appellation for a generic name; as in the caſes of *Cyamus*, Sm. Exot Bot. v. 1. 59. t. 31, 32 (ſee CYAMUS); and *Nuphar*, Prod. Fl. Græc. v. 1. 361.

2. E. *Barbarea.* Linn. Sp. Pl. 922. Engl. Bot. t. 443. "Lower leaves lyrate; their terminal lobe rounded: upper ones obovate, toothed."—Common in waſte ground, either dry or wet, flowering moſt in the ſpring. Its numerous *flowers* of a full yellow, often ſeen double in gardens, and its dark ſhining broad *leaves* eaſily diſtinguiſh it. The whole plant has a nauſeous, bitter, ſlimy flavour.

3. E. *præcox.* Sm. Fl. Brit. 707. Engl. Bot. t. 1129. "Lower leaves lyrate: upper ones pinnatifid, their ſegments linear, oblong, and entire."—Found in Devonſhire by the Rev. Dr. Beeke. The narrow lobes of the *ſtem-leaves*, ſmaller *flowers*, and much longer *pods*, diſtinguiſh this from the laſt, with which we believe Linnæus confounded it. The diſtinction is highly important, as we are convinced the preſent is the very ſame with the American Creſs, as it is called, or rather Winter Creſs, of the gardens, an agreeable and wholeſome pungent herb for ſallads, &c.

4. E. *Alliaria.* Linn. Sp. Pl. 922. Curt. Lond. faſc. 2. t. 48. Engl. Bot. t. 796. "Leaves heart-ſhaped."—Common under hedges in the ſpring, and known by its broad toothed *leaves*, white *flowers*, and ſtrong ſcent of garlick when bruiſed.

5. E. *cheiranthoides.* Linn. Sp. Pl. 923. Engl. Bot. t. 942. Jacq. Auſtr. t. 23.—"Leaves lanceolate, ſlightly toothed. Pods erect. Flower-ſtalks when in fruit ſpreading."—Not rare in Oſier-grounds, Turnip-fields, and other cultivated ground, where the ſoil is gravelly or ſandy, flowering in July. This reſembles the yellow ſtock or wall-flower in habit and *leaves*, but the ſmall *flowers* and ſquare *pods* at once diſtinguiſh it.

The exotic ſpecies are not quite ſo well aſcertained as ours. Ehrhart and Roth have taken pains to elucidate them, and the reſult is given by Willdenow. We know not that any of them is worthy of the attention of the cultivator except for botanical curioſity.—They are all either annual or biennial, perfectly hardy in our climate, and bear narrow lanceolate leaves, with ſmall yellow flowers. As weeds their copious ſeeds render them rather troubleſome.

ERYSIPELAS, from ερυω, *to draw*, and πελας, *near*, from the diſpoſition of the affection to draw the adjacent parts into the ſame ſtate; or from ερυθρος, *red*, and μελας, *black*, a dark red.) The generality of ſurgical authors have conſidered eryſipelas as a ſpecies of inflammation, and every reflection induces us to entertain the ſame opinion, notwithſtanding the oppoſite ſentiment of one of the lecturers on ſurgery in this metropolis. The immortal Celſus has obſerved: "notæ verò inflammationis ſunt quatuor; rubor, et tumor, cum calore et dolore," lib. 3. cap. 10. According to this definition, eryſipelas is certainly an inflammation, although the degree of ſwelling is not ſo great, nor the pain exactly of the ſame kind, as in caſes of phlegmon, or common inflammation.

With many diſtinguiſhed ſurgical authors, we regard eryſipelas as a particular kind of inflammation, moſt frequently affecting the ſmall veſſels on the ſurface of the body. It is, as Mr. Hunter deſcribes, more commonly a cutaneous inflammation, than one ſituated in deeper parts; although it is probable, that, in ſome conſtitutions, every inflammation, wherever it exiſts, will be of this kind. However, there can be no doubt of the fact laid down by this accurate obſerver, *viz.* that the ſkin appears to be the moſt ſuſceptible of eryſipelas, becauſe this affection will ſpread over a prodigious extent of the ſurface of the body, while (at leaſt, in common inſtances) the cellular membrane underneath remains free from diſorder. (See Hunter on Inflammation, p. 270.)

Mr. Hunter taught ſurgeons, that one of the uſes of the adheſions, which form in caſes of common inflammation, is to circumſcribe and bound the matter, in the event of ſuppuration taking place. Now, in eryſipelas, the extravaſation in the place affected is not ſo conſiderable as in phlegmon, nor is it of that kind, which produces adheſions among the inflamed parts. Indeed, ſince eryſipelas ſeldom ends in ſuppuration, ſuch adheſions, according to Mr. Hunter's view of the ſubject, would in general be unneceſſary. Perhaps, alſo, the circumſtance of there being no adheſions in eryſipelatous caſes, may account for the terrible diffuſion of miſchief, which always happens, when abſceſſes do occaſionally take place. Then, we know, that the matter makes its way extenſively through the cellular ſubſtance, in every direction under the ſkin, under faſciæ, and between the muſcles, producing, wherever it goes, what has been often named a gangrenous ſuppuration. When eryſipelas is of an unmixed kind, it has not the dark red colour which common inflammations have, but a lighter red, with a yellow tinge, which is particularly obſervable towards the termination of the diſorder. The ſwelling which occurs is unattended with any remarkable induration, and forms a very inconſiderable prominence. The ſkin of the inflamed part has a ſhining appearance, and, on being touched with the finger, turns white at the ſpot where the preſſure is made; but the bright red colour immediately afterwards returns. The pain is uſually of a burning, ſhooting deſcription, and the patient frequently complains of a ſort of itching, which is found to be particularly annoying. The ſwelling, which happens in caſes of eryſipelas, is not only not ſo hard and elevated as that which ariſes in examples of phlegmonous inflammation, it is at the ſame time not ſo clearly circumſcribed.

Another remarkable feature of eryſipelas, is the manner in which this inflammation often changes its ſituation, by getting well on one ſide, while it is ſpreading in ſome other direction. The great celerity with which the affection ſpreads, and the large ſurface which it in a very little while covers, may alſo be ſet down among its moſt ſtriking peculiarities.

When the affection is intimately dependent on the ſtate of the conſtitution, we very often ſee all the local ſymptoms recede in one place, and the diſeaſe make its attack in ſome other part of the body. Such inſtances are not unfrequently mentioned by writers as *metaſtaſes*, juſt as if it were a real fact, that, when the eryſipelatous ſymptoms get well on one leg, and the other leg becomes affected in a ſimilar way, theſe events happen, in conſequence of the firſt identical diſeaſe actually moving from one limb to the other. From this abſurd doctrine originates all the cant about the danger of uſing ſuch applications as are likely to repel the inflammation. The truth is, that the ſecond attack of the eryſipelas is not at all connected with the termination of the firſt; but ariſes from ſome different, and probably inexplicable cauſe, juſt as encyſted tumours will often form, one after another, in various parts of the body, as regularly as they are cut out. In this latter inſtance, no one is abſurd enough even to ſuſpect that the growth of one tumour is the effect of a previous one being cured.

In true eryſipelas, there is no throbbing of the part affected, as in caſes of phlegmon; and when eryſipelatous inflammation runs along the ſkin, the affection has a determinate edge, and does not loſe itſelf gradually and inſenſibly in the ſurrounding parts, as common inflammation does.

The alteration which the ſkin undergoes in eryſipelas conſiſts in its feeling at the part affected leſs pliable than in the natural ſtate, and a little thickened.

Such are the ordinary local ſymptoms of eryſipelas. They are ſubject, however, to ſome variety, depending on the mildneſs or violence of the attack, and on the circumſtance of the diſorder being either ſimple, or complicated with another affection; for inſtance, œdema, phlegmon, &c.

With reſpect to violence, eryſipelas may be very properly divided into three degrees. In the firſt, or mildeſt form of the complaint, the eryſipelas makes its appearance, without any preceding illneſs, or with only a ſlight indiſpoſition of ſhort duration, and conſiſting of laſſitude, diſturbed ſleep, loſs of appetite, &c. Theſe complaints very ſoon go off, when the eryſipelas comes out, which happens in about a couple of days. For two days more the local ſymptoms remain the ſame, and then the eryſipelas turns pale and yellow, gradually diſappearing altogether, with a detachment of the cuticle. During the whole courſe of the diſorder there is no fever of any conſequence; but a little while before the redneſs occurs the pulſe is ſometimes rather diſturbed.

In the ſecond, or more ſevere degree of the diſorder, the patient is troubled, about two days before the eryſipelas makes its appearance, with an unuſual proſtration of ſtrength, heavineſs in all his limbs, head-ach, loſs of appetite, nauſea, and even actual vomiting, complaints in the ſtomach, &c. Beſides theſe inconveniencies, the patient is affected with a fever, and all its uſual ſymptoms. After a couple of days, commonly on the third day from the commencement of all indiſpoſition, the eryſipelas comes out, attended with a gentle ſweat, and a moderate increaſe in the ſecretion of urine, after which circumſtances the fever, with all its attendant ſymptoms, goes off. The reſt of the progreſs of the caſe is ſimilar to what we have related, as happening in the firſt, or mildeſt attack of eryſipelas.

In the third, or moſt violent degree of the diſorder, particularly in thoſe caſes in which eryſipelas makes its attack on the face, the patient is affected with ſevere febrile ſymptoms, head-ach, loſs of ſleep, delirium, ſickneſs, &c. Theſe complaints do not diminiſh, as in the milder caſes of eryſipelas, when the local redneſs, heat, &c. take place on the third day; but continue with unabated vehemence, until the eryſipelas itſelf ſubſides. The laſt deſirable event commonly happens, according to Richter, on the eleventh day, accompanied with an increaſe in the ſecretions from the ſkin and kidnies.

The moſt dangerous caſes of eryſipelas are thoſe in which the face is affected. Of this form of the diſorder, the celebrated Cullen has left us a matchleſs deſcription, which we think is highly deſerving of inſertion in this Cyclopædia. The eryſipelas of the face, (ſays this intereſting author,) comes on with a cold ſhivering, and other ſymptoms of pyrexia. The hot ſtage of this is frequently attended with a confuſion of head and ſome degree of delirium; and almoſt always with drowſineſs, or perhaps coma. The pulſe is always frequent, and commonly full and hard.

When theſe ſymptoms have continued for one, two, or at moſt three days, there appears on ſome part of the face a redneſs, ſuch as that of erythema. This redneſs at firſt is of no great extent; but, gradually ſpreads from the part it firſt occupied, to other parts of the face, commonly till it has affected the whole; and frequently from the face it ſpreads over the hairy ſcalp, or deſcends on ſome part of the neck. As the redneſs ſpreads it commonly diſappears, or, at leaſt decreaſes in the parts it had before occupied. All the parts upon which the redneſs appears are at the ſame time affected with ſome ſwelling, which continues for ſome time after the redneſs has abated. The whole face becomes conſiderably turgid; and the eye-lids are often ſo much ſwelled, as entirely to ſhut up the eyes.

To continue Dr. Cullen's account: when the redneſs and ſwelling have proceeded for ſome time, there commonly ariſe, ſooner or later, bliſters of a larger or ſmaller ſize on ſeveral parts of the face; theſe contain a thin yellowiſh, or almoſt a colourleſs liquor, which ſooner or later runs out. The ſurface of the ſkin in the bliſtered places ſometimes becomes livid and blackiſh, but this livor ſeldom goes deeper than the ſurface, or diſcovers any degree of gangrene affecting the ſkin. On the parts of the face not affected with bliſters the cuticle ſuffers, towards the end of the diſeaſe, a conſiderable deſquamation.

Sometimes the tumours of the eye-lids end in a ſuppuration.

The inflammation coming upon the face does not produce any remiſſion of the fever which had before prevailed; and ſometimes the fever increaſes with the increaſing and ſpreading inflammation.

The inflammation uſually continues for eight or ten days; and, for the ſame time, the fever and ſymptoms attending it alſo continue.

In the progreſs of the inflammation, the delirium and coma attending it ſometimes go on increaſing, and the patient dies apoplectic, on the ſeventh, ninth, or eleventh day of the diſeaſe. In ſuch caſes, it has been commonly ſuppoſed that the diſeaſe is tranſlated from the external to the internal parts. But, Dr. Cullen obſerves, that he never met with any inſtance in which it did not appear to him, that the affection of the brain was merely a communication of the external affection, as this continued increaſing at the ſame time with the internal.

When the fatal event does not take place, the inflammation, after having affected a part, commonly the whole of the face, and, perhaps, the other external parts of the head, ceaſes. With the inflammation the fever alſo ceaſes; and, (ſays Cullen,) without any evident criſis, the patient returns to his ordinary ſtate of health.

The ſame diſtinguiſhed writer repreſents the diſeaſe as being not commonly contagious; but he conceived it poſſible that it might ſometimes be communicated from one perſon to another; and, he adds, that perſons who have once laboured under the diſorder are liable to returns of it.

According to Cullen, the event of the diſeaſe may be foreſeen from the ſtate of the ſymptoms which denote more or leſs affection of the brain. If neither delirium nor coma comes on, the diſeaſe is ſeldom attended with any danger; but when theſe ſymptoms appear early in the diſeaſe, and are in a conſiderable degree, the utmoſt danger is to be apprehended.

We have already remarked that, in caſes of eryſipelas, ſuppuration does not frequently happen; but that when it does, owing to the matter not being confined by the adheſive inflammation, very bad conſequences follow. Wherever the matter ſpreads, it occaſions under the ſkin an extenſive ſloughing of the faſciæ, tendons, and cellular ſubſtance, all which kind of miſchief may take place, while the ſkin itſelf, which is very vaſcular and highly organized, remains unimpaired in its texture. This combination of ſuppuration and mortification is more likely to happen when the eryſipelatous inflammation extends to a greater depth than common, ſo as to affect the cellular membrane. In this ſtate, as Mr. Hunter has well deſcribed, air, matter, and ſloughs, are all produced together under the ſkin, and, on handling the part, a ſtrange feel is communicated, neither like that of a fluctuation, or a crepitation. Mr. John Pearſon very whimſically, we will not ſay unaptly, compares the ſenſation with that excited by a quagmire or moraſs. Frequently, the practitioner may obſerve in ſome opening, made either by ulceration or the lancet, a ſmall black ſloughy point, and, on taking hold of it with a pair of forceps, and drawing it out, he finds, to his great ſurpriſe, that a whole mortified tendon, of conſiderable length, follows his inſtrument.

Eryſipelas is to be met with more frequently in ſummer than winter, and more commonly in hoſpitals than other places. Wounds of the head, oftener than any other kind of accident, give riſe to the diſorder.

Eryſipelas has ſometimes been obſerved on the ſkin of new-born infants. Several inſtances of this kind are mentioned in the Medical Communications, as having occurred in the Britiſh Lying-in-Hoſpital. In one of theſe examples, the child was born with its whole face ſwelled and inflamed, the left ſide being affected with a true eryſipelas. There was alſo an inflammation on the legs, feet, and left hand. On each tibia, there appeared an oblong ſlough, of a dark brown colour, almoſt livid; the one on the left leg was exceedingly large. The cure was attempted by employing embrocations, emollient poultices, and fomentations, and applying camphorated ſpirit of wine. This child appears to have ſwallowed the decoction of bark with great eaſe, as it took four ounces of it every day from the very time of birth. In three days the ſwelling of the face and other parts had conſiderably ſubſided; but, on the third day, a veſication began to form on the left cheek, and another juſt above the eye-brow, on the ſame ſide. Theſe veſications increaſed in number and ſize, eſpecially on the legs, where they extended over the whole limb. Some confectio cardiaca was added to the decoction of bark, and pledgets, dipped in oil of turpentine, were put on all the parts affected, previouſly to the application of the poultice. The veſications began to break on the ſixth day, and a ſanies to iſſue from them; yellow ſloughs alſo now made their appearance in different parts. The child ſeemed much debilitated, and, for the laſt three or four days, had taken eight ounces of the decoction of bark, with one dram of the confectio cardiaca every twenty-four hours. The pledgets, applied to the ſores, were dipped in a digeſtive ointment, with oil of turpentine, and ſome cataplaſm e cymino. Under this mode of treatment, the ſloughs were ſoon detached, and the child recovered. though not without the loſs of the little finger, two joints of the ring finger, and one of the middle one.

The diſtemper, which we have juſt been deſcribing, for ſome time proved extremely fatal, none of the infants recovering who were attacked. However, bark is ſtated to have acted quite as a ſpecific remedy for the diſeaſe, as ſoon as it was tried, and almoſt all the children are ſaid to have got well who took this medicine. Mortification always took place in ſuch ſubjects as died; and the danger was regularly obſerved to be the greateſt in the inſtances in which the genitals were the parts firſt attacked. The diſeaſe was alſo noticed to affect the children of weakly women, and of ſuch as were addicted to drinking ſpirits.

To return, however, to our account of the common forms of eryſipelas, we have to appriſe the reader, that the term "St. Anthony's fire," which is ſo frequently mentioned by all ſorts of perſons, is ſtrictly applied by medical writers and practitioners to that ſpecies of the affection in which veſicles ariſe upon the ſurface of the ſkin; while other inſtances, not accompanied with veſications, are named *ſimple* eryſipelas.

The diviſion of the ſubject, however, cannot be properly comprehended under theſe two varieties; and the generality of authors have found it neceſſary to obſerve other diſtinctions.

Mr. Pearſon, in his Principles of Surgery, has noticed the following ſpecies of the complaint:

1. The acute eryſipelas.
2. The œdematoſe eryſipelas.
3. The malignant, or gangrenous eryſipelas.

Each of theſe ſpecies may be an idiopathic, or ſymptomatic diſeaſe.

Mr. Pearſon remarks, that the acute eryſipelas is moſt commonly ſeen in thoſe of a ſanguine and choleric temperament; it is generally ſudden in its attack, and uſually affects the face. Febrile ſymptoms are often preſent immediately after the acceſſion of the diſeaſe; but they gradually diminiſh as the eryſipelas becomes more diſtinctly formed. Conſiderable heat, and great uneaſineſs, take place in the part affected; the ſkin is alſo of a brighter ſcarlet colour than in the other ſpecies. If puſtules appear, they are diſtinct; but ſometimes there are no veſications on the ſurface.

Suppuration very rarely occurs in this kind of eryſipelas, and the violence of the diſeaſe commonly ſubſides in three or four days; the part then grows yellowiſh, and throws off furfuraceous ſcales. The diſeaſe terminates about the tenth day. A tenderneſs of the hairy ſcalp will often continue for a conſiderable time after the diſeaſe has diſappeared.

The acute eryſipelas, as we have already obſerved, is ſometimes an idiopathic affection; frequently it is ſymptomatic, or, in other words, the conſequence of a wound, eſpecially one of the head. Perſons who have once been attacked with the acute eryſipelas, in a ſpontaneous manner, are particularly liable to ſuffer again from future attacks of the ſame diſorder.

Mr. Pearſon ſtates, that the œdematoſe eryſipelas is not, in general, ſo ſudden in its attack, nor ſo ſevere on its acceſſion, as the acute eryſipelas. The diſeaſe increaſes gradually, is more diffuſed, and is attended with leſs burning pain. If febrile ſymptoms ſhould ariſe, they never run high, nor are they of long duration; moſt commonly the ſtrength is depreſſed, attended with a ſoft, frequent, perhaps, irregular pulſe. In this ſpecies of eryſipelas no conſtitutional relief is derived from the appearance of the local affection: on the contrary, the danger increaſes with the progreſs of the external diſeaſe.

When the face is the ſeat of the œdematoſe eryſipelas the whole countenance has a bloated appearance. The red colour of the ſkin is mingled with yellow or brown, and the complaint is attended with ſhiverings, vomiting, and more or leſs diſturbance of the functions of the brain. Mr. Pearſon further remarks, that the veſications are often ſmall and numerous, and, that when they have been expoſed for a few days to the air, the countenance becomes covered with a dark-coloured cruſt, very much reſembling the appearance which ariſes in the confluent ſmall-pox. Though the face is very much ſwelled, it is not firm to the touch, and eaſily yields to preſſure.

The œdematoſe eryſipelas is deemed highly dangerous. Patients often die, in a delirious or comatoſe ſtate, about the ſeventh day, ſometimes a little later.

It is common to ſee many people afflicted with this ſpecies of eryſipelas about the ſame time. Mr. Pearſon informs us, that, in hoſpitals, he has ſeen ſeveral perſons ſucceſſively attacked with the complaint in the ſame ward. Some conjectures have been entertained of the diſorder being contagious.

All ages and conſtitutions may be affected with the œdematoſe eryſipelas. However, ſubjects weakened by age, or intemperance, are moſt frequently attacked. Dropſical patients, children, and new-born infants, are alſo ſeen affected with the complaint.

According to Mr. Pearſon, the œdematoſe eryſipelas, when ſymptomatic, is much leſs dangerous than when idiopathic; but, ſays this author, whenever the face is conſiderably affected, the diſeaſe is always to be regarded as a ſerious one, whatever be the remote cauſe. On the limbs it is ſeldom dangerous, or very afflicting, unleſs treated in an improper way. Mr. Pearſon mentions his having ſeen the œdematoſe eryſipelas make its firſt appearance upon the face, and, by a gradual and regular progreſſion, proceed downward to the extremities, ſucceſſively appearing upon an inferior portion of the body, as it diſappeared from a ſuperior part. Each renewed acceſſion of the complaint was leſs and leſs ſevere, as it receded to a greater diſtance from the part that was primarily affected.

The malignant, or gangrenous eryſipelas, makes its firſt appearance ſomewhat like the œdematoſe form of the diſorder. Its progreſs, however, is much quicker. Phlyctenæ, with a livid baſe, ſoon occur on the ſkin, together with gangrenous ſymptoms. The diſeaſe, at a very early period, becomes attended with a ſtate of the conſtitution, reſembling that which exiſts in putrid fevers.

The gangrenous eryſipelas moſtly occurs on the face, neck, breaſt, and ſhoulders: the danger of the diſeaſe depends very much on the ſtate of the conſtitution.

When an eryſipelatous inflammation, particularly one of the legs has been cured, a degree of œdema will frequently continue about the lower part of the limb for ſome time afterwards.

Eryſipelatous inflammation differs from phlegmon in the following reſpects. The ſwelling is leſs prominent; and is never diſtinctly circumſcribed. The ſkin often has the appearance of being ſcorched, or burnt. The redneſs is quite circumſcribed, has a very determinate edge, is frequently tinged with yellow, and, on being touched with the end of the finger, a white ſpot is produced for a ſhort time in the place where the preſſure was made. The pain is not of the lancinating, throbbing kind, which attends phlegmonous inflammation; but is ſuch as cauſes a ſenſation of a great heat and burning in the part, together with a violent degree of itching. The part affected does not preſent the feel of, what ſurgeons underſtand by, tenſion; but only ſeems to the touch as if the ſkin were a little thickened. Except in the acute eryſipelas, there is no hardneſs of the pulſe, as in caſes of phlegmon, and inſtead of being attended, as the latter affection, with rather an increaſe of ſtrength, eryſipelas is almoſt always accompanied with more or leſs debility.

With reſpect to the cauſes of eryſipelas our knowledge is very imperfect, and every obſervation on this ſubject muſt be received with doubt. We do not mean to ſtate, that the remote cauſes are not very often ſufficiently obvious. We frequently have occaſion to remark, in the practice of ſurgery, that certain punctured wounds, and injuries of the external parts of the head give riſe to eryſipelas. Indeed, we may ſtate, as a general remark, that the ſame claſs of irritations, termed *remote* cauſes, which in one conſtitution would occaſion phlegmonous inflammation, in another would excite eryſipelas. What is far more difficult of inveſtigation, is the cauſe why eryſipelas ſhould take place rather than common inflammation; in other words, the exact particularity, to which the origin of eryſipelatous inflammation is to be aſcribed, is involved in much more obſcurity. Sometimes even the remote cauſe cannot be diſcovered, the affection having the appearance of originating in a ſpontaneous manner.

It was one of the ancient doctrines, eſtabliſhed by Galen, and maintained down to the preſent time, that what is underſtood by a bilous habit is particularly ſubject to eryſipelatous inflammation. Many parts of the writings of the celebrated Pott, the experienced Richter, and other noted modern writers, evince their belief in this opinion.

Weak and irritable conſtitutions appear to us to be moſt ſubject to eryſipelas; while ſtrong, plethoric perſons moſt frequently undergo common phlegmonous inflammation. We think, that there is every reaſon to believe, that, in general, eryſipelas is intimately dependant on the ſtate of the conſtitution, or on ſome peculiarity of temperament. This opinion is ſomewhat confirmed by the fact, that while perſons, who lead drunken, intemperate lives, are particularly often afflicted with eryſipelatous inflammation, in conſequence of local injuries, other people, who lead more regular lives, generally have phlegmonous inflammation after ſimilar injuries.

It muſt be admitted, however, that eryſipelas occaſionally makes its appearance in conſtitutions with which we can find no evident fault. Indeed, Hunter ſeems to have conſiderable reaſon for his inference, that the affection may, in ſome inſtances, be altogether independent of conſtitutional cauſes, ſince it is the common courſe of the diſeaſe to be actually getting well on one ſide as faſt as it is ſpreading on another.

If we can ſometimes aſſign particular circumſtances, which operate as cauſes conducive to eryſipelas, it is all that we can hope to do. To trace the proximate cauſe in every example which preſents itſelf, is far beyond our pretenſions; neither do we believe that it is to be done by the powers of human reſearch. We might adopt the language of Cullen, and talk of eryſipelas depending "on a matter generated within the body, and thrown out, in conſequence of fever, upon the ſurface of the body." We might alſo join Mr. Pearſon in repreſenting eryſipelas as being ſometimes the "critical termination of another diſeaſe, ſuch as obſtructed menſtruation, quartan ague, ſuppreſſed ſuppuration, ſpaſmodic and convulſive diſeaſes." However, we ſhould ſhew juſt as much devotion for truth, were we to offer any other wild, vague ſuppoſitions, unſupported by rational evidence.

Leſs aſpiring in our attempts, we ſhall only aim at pointing out circumſtances which ſeem to act as cauſes, conducive to the diſorder, in ſome inſtances. If many women of temperate lives, and young children, are occaſionally affected with eryſipelas, as they undoubtedly are, the fact only proves, that there are other cauſes beſides intemperance which may be concerned in giving riſe to the complaint. The ſources of the diſeaſe muſt, we believe, on ſome occaſions, be regarded as among the myſterious and inacceſſible ſecrets of nature. When drunkenneſs and other kinds of intemperance are aſſigned as cauſes conducive to eryſipelas, it is not meant that they are excluſively ſo. There are, probably, hundreds of other cauſes in exiſtence, though we may not be able to detect them.

With regard to women of temperate regular lives, and to children being occaſionally affected with eryſipelatous inflammation, the fact cannot be called in queſtion. But, ſtill, no experienced man will contend that ſuch ſubjects are attacked with eryſipelas, on meeting with local injuries, half ſo frequently as perſons with conſtitutions impaired by any kind of intemperance, habits, or modes of life.

Richter and ſome other writers, have deſcribed eryſipelas as depending very much on a ſuppreſſed ſtate of the perſpiration; but we are inclined to think that they have aſcribed the importance of a cauſe to a mere effect of the fever, with which eryſipelas is connected.

Treatment of the acute, or phlegmonous eryſipelas.—This ſpecies of the diſeaſe being commonly attended with a full, and frequently a hard pulſe; the blood drawn ſhewing upon its ſurface the buffy coat to be ſeen in all inflammatory complaints; and laſtly, the ſwelling of the eyelids, frequently ending in ſuppuration; there can be no doubt, that the affection ſhould be treated very much in the ſame manner as phlegmonous inflammation. Blood-letting, cooling purgatives, and every part of the antiphlogiſtic regimen, are adviſed by Cullen, who affirms, that his experience had confirmed the fitneſs of this method of cure.

The evacuations of blood-letting and purging are to be employed, more or leſs, according to the urgency of the ſymptoms, particularly the febrile ones, and thoſe which mark an affection of the brain.

Although Mr. Pearſon mentions general and topical bleeding as being indicated in the treatment of the acute eryſipelas, yet he obſerves, that caſes very rarely occur in large towns where bleeding is at all admiſſible, and a repetition of the operation can very ſeldom be proper.

Profeſſor Richter ſtrongly praiſes the good effect of emetics on eryſipelas; but ſome other writers, probably in a ſtrain of ignorance, or prejudice, repreſent ſuch medicines as having ſometimes occaſioned fatal conſequences.

Another indication is to promote a gentle degree of perſpiration. For this purpoſe, we may exhibit ſmall doſes of the antimonium tartariſatum, or the pulvis ipecacuanhæ comp., æther vitriolicum; ſaline draughts with volatile alkali, &c.

Opium and camphor are alſo proper remedies for allaying irritation.

Whoever has been in the habit of conſulting the writings of ſeveral celebrated medical authors, will perceive that they place great reliance in bark, as a medicine tending very powerfully to check and cure eryſipelatous inflammations. When we mention Mr. John Hunter among ſuch authors, our readers will be inclined, perhaps, to ſuſpect that there muſt be ſome foundation for the repute into which this medicine has riſen for the complaints under conſideration. However, we muſt confeſs our own belief, that bark gained credit for its good effects on eryſipelas entirely in conſequence of the general enthuſiaſm which once depicted it as a cure for almoſt every diſeaſe of the human frame. The ſentiment is corroborated, if not confirmed, by the fact, that the beſt modern practitioners ſeem now to conſider bark no longer of eminent ſervice in caſes of acute eryſipelas.

With reſpect to local applications, in theſe inſtances, ſeveral kinds have been uſed by different practitioners. Cold aſtringent lotions, oily ſubſtances, rubefacients, farinaceous, or earthy powders, and emollient poultices, have all been tried. As far as our experience extends, the lotio aquæ lithargyri acetati is as good an application as can be made to a part affected with the acute ſpecies of eryſipelas. However, it becomes us to appriſe the reader, that the majority of medical writers beſtow the greateſt praiſe on the employment of dry mealy powders, ſuch as flour, ſtarch, &c. for topical remedies, with which the inflamed part is to be covered.

Mr. Pearſon, ſtrangely enough, ſpeaks in favour of rubefacients, as if the ſkin were not already reddened enough by the diſeaſe; but reſerves his higheſt recommendations for mild warm poultices. Let the ſurgeon, however, conſider the ill conſequences and terrible miſchief which always occur when ſuppuration ſupervenes, and let him beware of the injudicious plan of promoting the latter event.

Treatment of the œdematoſe eryſipelas.—In this caſe topical bleeding may be practiſed; but veneſection is hardly ever allowable. The bowels ſhould be kept open with ſaline purgatives of the mildeſt deſcription, and a gentle perſpiration ought to be excited, by means of ſmall doſes of tartariſed antimony, the pulvis ipecacuanha comp., &c. For the purpoſe of appeaſing pain and irritation, the practitioner may preſcribe camphor, opium, æther, &c.

When the patient's conſtitution is in a debilitated condition, tonics are indicated, together with the moſt nouriſhing food. Bark, wine, porter, brandy, the confectio aromatica, may now be found of the utmoſt ſervice.

Treatment of the malignant or gangrenous eryſipelas.—Little need be ſaid here on this ſubject, as the mode of treatment is the ſame as that of mortification in general. See Gangrene.

The grand objects are; to ſupport the patient's ſtrength; to cover the parts affected with emollient poultices; to foment them two or three times a day with a decoction of poppy-heads; to make depending openings for the eſcape of the matter and ſloughs; and remove the dead parts, as ſoon as it can be done without occaſioning the leaſt irritation and pain.

We have frequently ſeen the gangrenous miſchief ſo extenſive in theſe caſes, that amputation of the limb was the only means of ſaving the patient from deſtruction. See Richter's Anfangſgründe der Wundarzneykunſt. Band i. Von der Roſe. Pearſon's Principles of Surgery. Cullen's Firſt Lines of the Practice of Phyſic. Cooper's Firſt Lines of the Practice of Surgery.

ERYSIPHE, in *Agriculture*, a term applied by ſome to that vegetable diſeaſe generally known by the name of mildew. See Mildew.

ERYSTHIA, in *Ancient Geography*, a town of the iſland of Cyprus. Steph. Byz.

ERYTHEIA, an iſland of Iberia, in the ocean. According to Strabo, it was ſeparated from the continent by a large ſtrait of a ſtadium, or, according to Pliny, of 100 paces. It was near Gades. Its name was derived from the Phœnicians, who, having inhabited the banks of the Erythrean ſea, came to ſettle here. It was alſo called *Aprodiſias*, or the iſle of Venus, and the iſle of Juno. See Gades.

ERYTHE'MA, in *Surgery*, (from ερυθος, *red.*) The celebrated Cullen diſtinguiſhed two claſſes of eryſipelatous inflammations. When the diſeaſe was an affection of the ſkin alone, and very little of the whole ſyſtem, or when the affection of the ſyſtem was only ſymptomatical of the external inflammation, he called the diſeaſe *erythema;* but when the external inflammation was an exanthema, and ſymptomatical of an affection of the whole ſyſtem, he named the diſeaſe *eryſipelas*, which ſee.

"An Erythema, Roſe, or St. Anthony's Fire, (ſays Dr. Cullen) is an inflammatory affection of the ſkin, with hardly any evident ſwelling; of a mixed, and not very bright red colour, readily diſappearing upon preſſure, but quickly returning again; the redneſs of no regular circumſcription, but ſpreading unequally, and continuing almoſt conſtantly to ſpread upon the neighbouring part; with a pain like to that from burning; producing bliſters, ſometimes of a ſmall, ſometimes of a larger ſize, and always ending in a deſquamation of the ſcarf-ſkin, ſometimes in gangrene."

We need not enlarge on the ſubject of erythema, in the ſenſe of an eryſipelas not originating from a conſtitutional affection, as every uſeful information, concerning eryſipelatous inflammations in general, is to be found in the article Eryſipelas.

The chief object which we have in view in the preſent part of this work is to deſcribe a particular affection of the ſkin, named, in conſequence of its being occaſioned by the uſe of mercury, the *mercurial erythema*, or *eczema*.

It was perhaps, for the firſt time, diſtinctly noticed and deſcribed by Mr. Benjamin Bell in his Treatiſe on the Venereal Diſeaſe. "It is not an uncommon effect of mercury (ſays this author) to excite an eruption upon the ſurface of the body. In ſome, this appears as a miliary raſh, ſomewhat reſembling meaſles; while in others it is conſiderably elevated, and ſeems to be produced by a ſerous effuſion between the cutis and ſcarf-ſkin. In ſome the eruption is partial, being confined to particular ſpots; while in others it prevails generally over the whole body.

"This eruption, or efflorеſcence, is not attended with pain; but the heat and itchineſs which accompany it are, in ſome inſtances, ſo diſtreſsful, that it keeps the patient at all times very uneaſy, and deprives him entirely of reſt.

"The remedies, (obſerves Mr. B. Bell) which I have found to anſwer the beſt, are the internal uſe of opiates, conjoined with the application of flour or ſtarch-powder to the parts affected. The ſkin is kept ſufficiently cool and eaſy by one or the other of theſe powders being from time to time freely applied to the eruption; and, by a proper exhibition of opiates we ſecure reſt during the night. In ſome inſtances, however, we are obliged to avoid the uſe of opiates; for although they may anſwer the purpoſe of procuring ſleep, they tend evidently to increaſe the heat and itchineſs of the eruption. We find, indeed, that, in ſome conſtitutions, opium excites an uneaſy itchy ſenſation over the whole body, even where an eruption has previouſly taken place: and it is, perhaps, with ſuch patients only, that it cannot be employed in the treatment of this eruption.

"The eruption to which I allude, (adds Mr. Bell,) appears to ariſe entirely from the effect of mercury upon the ſyſtem; but it does not ſeem to depend upon any particular preparation of the remedy. It takes place indiſcrimately from all of them; and not more readily from unction than from thoſe preparations that are uſed internally." See a Treatiſe on Gonorrhæa Virulenta and Lues Venerea; by B. Bell, vol. ii. p. 228.

Since this gentleman publiſhed the foregoing work, the mercurial erythema has excited conſiderable attention, and ſeveral writers, *viz.* Drs. Moriarty, M'Mullin, and Spens, and Meſſrs. Alley and Pearſon, have endeavoured to render our knowledge of the ſubject more extenſive.

Dr. M'Mullin judiciouſly obſerves, that eruptions of various kinds are very common ſymptoms of ſyphilis, but a very unuſual effect of mercury. Hence, until the real nature of the mercurial erythema was aſcertained, whenever the affection occurred in patients undergoing a mercurial courſe for ſyphilitic complaints, it was naturally enough conſidered as an anomalous form of lues venerea. The mercury was conſequently puſhed to a greater extent, in proportion to the violence of the ſymptoms, and from the cauſe of the diſeaſe being thus unconſciouſly applied for its removal, it could not fail to be aggravated, and hurried on to a fatal termination. At length, the obſervation of this fact, and of another truth, that a ſimilar eruption did ſometimes appear in patients who were uſing mercury for other complaints, and in whom no ſuſpicion of ſyphilis could be entertained, led to the important diſcovery that the eruption was entirely an effect of mercury, and not at all connected with the original diſeaſe.

Dr. M'Mullin imputes the firſt explanation of the nature of the mercurial erythema to Drs. Moriarty and Spens, and Mr. George Alley, all which writers publiſhed in the courſe of the ſame year, *viz.* 1804. However, the paſſage which we have quoted above, from Mr. B. Bell's work on the venereal diſeaſe, clearly evinces that though the above gentlemen have undoubtedly great merit in having increaſed our information concerning the diſeaſe, yet the latter writer had noticed the affection before them. Indeed, Dr. Spens has had the liberality to make this acknowledgment himſelf.

According to Dr. M‘Mullin, the different appearances which this diſeaſe aſſumes, from its ſeverity and duration, may be beſt underſtood by deſcribing it as conſiſting of three diſtinct ſtages. The firſt ſtage, ſays this gentleman, commences with languor, laſſitude, and cold ſhiverings. Theſe ſymptoms are ſucceeded by increaſed temperature of the body, quick pulſe, nauſea, head-ach, and thirſt. The patient is troubled with a dry cough, and complains of difficult reſpiration, anxiety, and ſenſe of ſtricture about the præcordia. The tongue is uſually moiſt, and covered with a white glutinous ſlime. It ſometimes appears clean and of a bright red colour in the centre, while the margins remain foul. The ſkin feels unuſually hot and itchy, with a ſenſe of prickling, not unlike the ſenſation experienced from the application of nettles. The belly is generally coſtive; but a diarrhœa is often produced by very ſlight cauſes.

To continue Dr. M‘Mullin's deſcription: on the firſt, or ſecond day, an eruption moſt commonly appears, the colour of which is either dark or bright red. The papulæ are at firſt diſtinct and elevated, very much like thoſe which occur in rubeola. Sometimes, but not often, the eruption appears like urticaria, and in ſuch inſtances the diſeaſe is obſerved to be very mild. The papulæ very ſpeedily run together in ſuch a manner as to form a ſuffuſed redneſs, which diſappears on preſſure. In moſt caſes, it firſt begins on the ſcrotum, inſide of the thighs, fore-arm, or where mercurial frictions have been made, and the ſkin of the parts affected becomes conſiderably ſwollen. Inſtances have alſo been ſeen in which an eruption of a purpliſh colour, and accompanied by papulæ, has ſuddenly diffuſed itſelf over the whole body. (See Moriarty on Lepra Mercurialis.) Dr. M‘Mullin remarks, however, that the latter form of the affection may be conſidered as uncommon. In every inſtance which Dr. M‘Mullin has ſeen the eruption was at firſt confined to a few places, and thence gradually extended, until the different portions of the eruption had united. The papulæ were alſo rough to the feel. But, in ſuch caſes as reſemble urticaria, many minute veſicles, interſperſed among the papulæ, and containing a ſerous fluid, make their appearance from the very firſt. Contrary to what happens in moſt diſeaſes, accompanied with cutaneous affections, the febrile ſymptoms are much aggravated, and continue to increaſe, after the eruption is complete. The pulſe in general beats from 120 to 130 in a minute, the thirſt continues urgent, and the patient, who is extremely reſtleſs, ſeldom enjoys quiet ſleep. Dr. M‘Mullin further informs us, that when the eruption has continued in this manner, for a certain period, the cuticle begins to peel off in thin, whitiſh, ſcurfy exfoliations, not unlike thoſe obſerved in rubeola. This deſquamation firſt begins where the eruption made its earlieſt appearance, and in this order ſpreads to other parts. About this period the fauces become ſore, the tongue ſwells, and the eyes appear ſomewhat inflamed.

The duration of this ſtage is very various; ſometimes it continues from ten to fourteen days, and in other caſes it terminates in half that time. When the diſeaſe has appeared in its mildeſt form, the patient recovers immediately after this deſquamation, a new cuticle having formed underneath. When the diſeaſe is ſevere, however, he has only experienced the ſmalleſt part of his ſufferings, and the ſkin now aſſumes a new appearance, which Dr. M‘Mullin has conſidered as the ſecond ſtage.

This author repreſents the ſkin as appearing at this period as if ſtudded with innumerable minute veſicles, which are filled with a pellucid fluid. Theſe veſicles (he obſerves) may be expected, if the patient, at the cloſe of the firſt ſtage, ſhould complain of increaſed itching, and a ſenſe of a burning heat in the parts, from which the cuticular exfoliations have fallen. The veſicles ſometimes remain for a day or two; but in general they are burſt immediately after their formation, by the patient rubbing the parts, in order to relieve the troubleſome itching which he ſuffers. A ſerous acrimonious fluid is diſcharged, which poſſeſſes ſo diſagreeable an odour, that it induces nauſea in the patient himſelf, and thoſe who approach his bed-ſide. The ſmell is ſaid to be ſo peculiar, that it can be eaſily recogniſed by any perſon who has once perceived it. Dr. M‘Mullin ſtates, that this fluid is poured out moſt copiouſly from the ſcrotum, groin, inſide of the thighs, or wherever the ſkin forms folds, and ſebaceous glands are moſt numerous. The ſerous diſcharge from the veſicles forms, with the cuticle, incruſtations, which Dr. M‘Mullin regards as the criterion of the third or laſt ſtage.

The ſame writer obſerves, that the cruſts are generally very large, and when detached retain the figure of the parts from which they have fallen. Their colour is in general reddiſh, but it ſometimes appears dark and dirty. Dr. M‘Mullin conceives, that this period of the diſeaſe might be termed, with much propriety, the ſtage of *decruſtation*, in order to diſtinguiſh it more fully from the *deſquamation*, which has been already noticed. When the ſtage of decruſtation appears, the fauces become more affected, the eyes intolerant of light, and the tarſi tender, inflamed, and ſometimes turned inward. The cruſts formed on the face, as in other parts of the body, before falling off, break ſo as to leave cracks and fiſſures, which horridly deform the countenance; and in conſequence of the great ſwelling of the face the eye-lids are alſo completely cloſed. The back and hairy ſcalp are ſaid to be the parts moſt backward in becoming affected, and, according to Dr. M‘Mullin's account, they even ſometimes eſcape entirely in very ſevere caſes.

In this ſtage of the mercurial erythema the patient is under the neceſſity of avoiding every kind of motion, on account of the pain which it occaſions, and which he compares with ſuch a ſenſation as one may fancy would be produced by a cracking of the fleſh. The cruſts alſo fall off in ſuch abundance, that the bed ſeems as if ſtrewed with the cones of hops.

While the eruption is only making its appearance in one place, it may have attained its moſt advanced form in another part, ſo that all the different ſtages of the diſeaſe may be preſent at one time, in the ſame individual.

Typhus prevails throughout the whole courſe of the complaint; but, what is curious, the appetite continues in moſt caſes unimpaired, and ſometimes is even voracious.

Dr. M‘Mullin alſo remarks, that when the catarrhal ſymptoms have continued during the progreſs of the complaint, they are particularly aggravated in the advanced ſtage of the caſe. The anxiety and pain in the breaſt are likewiſe ſtated to be very ſevere, attended with cough and bloody expectoration, the patient invariably feeling languid and dejected. The pulſe becomes frequent, feeble, and irregular; the tongue black and parched; and, at length, diarrhœa, delirium, convulſions, gangrene of the ſurface of the body, and death, enſue.

The mild form of the diſeaſe only goes through the firſt ſtage, and ends, as we have already deſcribed, in a ſlight deſquamation, after a few days. When the affection is ſevere, however, it is often protracted more than two months, every ſtage of the eruption continuing proportionably longer; and when, in this manner, it has run its courſe, it repeatedly breaks out on the new ſurface, and paſſes through the ſame ſtages.

For the preceding hiſtory of the ſymptoms of the mercurial erythema, we feel ourſelves highly indebted to Dr. M'Mullin. See Edinburgh Medical and Surgical Journal, vol. ii. p. 25, &c.

With the exception of one caſe, which Dr. Rutter has inſerted in the eighteenth number of the journal juſt now mentioned, we have no inſtance recorded, in which the preſent diſorder originated, without the patient being under the influence of mercury. Whether Dr. Rutter's example is to be conſidered as the ſame identical diſeaſe as the one which we have been deſcribing, we ſhall not undertake to inveſtigate. We ſhall only obſerve, that ſince it is very poſſible to miſtake other complaints for the real mercurial erythema, we do not conſider one ſolitary fact, reſting on the judgment of an individual, who might differ in opinion concerning the nature of the diſeaſe, with the next medical practitioner conſulted, a ſufficient ground for implicitly believing, that ſuch a diſeaſe as the mercurial erythema can be produced quite independently of the uſe of mercury.

In certain habits, every preparation of mercury, and every form of employing this medicine, ſeem capable of bringing on the diſeaſe. As the complaint was firſt taken notice of in patients who were afflicted with ſyphilis, it was ſuppoſed to be an anomalous form of the venereal diſeaſe. But, at laſt, the repeated appearance of the eruption in perſons exempt from all ſuſpicion of having any ſyphilitic ſymptoms, made ſurgeons convinced, that what is now commonly named the mercurial erythema had nothing venereal in its nature. However, ſince few out of the great number of patients, continually employing mercury, are afflicted with this erythema, medical writers have attempted a further explanation of the difficult ſubject of cauſes, by ſtating, that the mercurial erythema only takes place in ſuch patients as have a certain undeſcribable peculiarity of conſtitution. The contemplative reader will at once perceive, that this is a vague and an unphiloſophical mode of accounting for the production of the diſeaſe, as the ſame ſorry kind of explanation may be generally adopted in regard to every diſorder, the immediate cauſe of which is totally unknown. Is it not a greater mark of prudence and good ſenſe to confeſs our ignorance, under theſe circumſtances, than to offer ſtatements, wiſhing them to be conſidered as explanatory, while they do not convey any information whatever on the ſubject?

It has been ſuppoſed by ſome, among whom is Dr. Gregory of Edinburgh, that the application of cold to the body, while under the influence of mercury, is abſolutely eſſential to the production of the diſorder under conſideration.

Notwithſtanding there can be no reaſonable doubt that the mercurial erythema is commonly excited by the uſe of mercury in ſome form or another, yet it appears from what Mr. Pearſon has ſtated, that the diſeaſe is not always exaſperated by a perſeverance in the employment of the medicine. On ſome particular occaſions, when this gentleman judged it to be of great moment to continue the mercurial frictions, the eruption neither ſpread univerſally, nor was it materially increaſed. The patients, however, did not get rid of the raſh till the mercury was diſcontinued.

We have already noticed the opinion of Dr. Gregory and ſome other practitioners, that expoſure of the body to cold, at a time when the ſyſtem is under the influence of mercury, is abſolutely neceſſary for the production of the mercurial erythema. Mr. Pearſon ſeems to entertain a very different ſentiment; for, he obſerves, that he is not aware of any other cauſe, than the action of mercury on a particular kind of conſtitution being concerned. He acquaints us, that he has ſeen this cutaneous diſeaſe occur in private practice as well as the Lock hoſpital, where the ſtricteſt attention has been paid to the temperature of the apartment, to regimen, and to perſonal cleanlineſs. He has had no reaſon to believe that any one ſeaſon of the year is more conducive to the diſeaſe than another; and he ſtates that free expoſure to the air, either in winter or ſummer, has not the leaſt perceptible effect in exciting the eruption.

Mr. Pearſon, as a general rule, recommends the employment of mercury to be immediately left off on the firſt appearance of the eruption; and though he ſeems to admit that the affection may be relieved by remedies, yet he is doubtful whether any plan of treatment has the power of interrupting its regular courſe, or abridging its duration. Mr. Pearſon would by no means wiſh to inſinuate, however, that the patient may not derive conſiderable benefit from medical aſſiſtance; his ſufferings (he owns) may be greatly mitigated; many inconveniences may be remedied; his ſtrength may be ſupported; and, in ſhort, (ſays Mr. Pearſon,) he may be ſo conducted through the diſeaſe, that his general ſtate of health ſhall not ſuffer any material or permanent injury.

It is not enough to diſcontinue the employment of mercury. In large hoſpitals, and particularly ſuch as are appropriated to venereal caſes, the patient ſhould be immediately removed from thoſe wards which may have their atmoſphere vitiated by the breathing of perſons charged in general with mercury.

In the early ſtage of the mercurial erythema, Mr. Pearſon recommends ſmall doſes, of antimonial powder, with ſaline draughts, or elſe the ammonia acetata. A gentle purgative ſhould be given every three or four days, and opium is proper for appeaſing the pain and irritation, and procuring ſleep. Sometimes, ſays Mr. Pearſon, opium mixed with camphor, or Hoffman's anodyne liquor, will have a better effect than when adminiſtered alone. When the diſcharge is no longer ichorous, and the tumefaction is ſubſiding, the ſame ſurgeon preſcribes the liberal exhibition of ſarſaparilla and bark. He has alſo thought, that the general ſenſe of uneaſineſs has been leſſened by the vitriolic acid, which proves at the ſame time grateful and refreſhing.

The diet ſhould be of a light and nouriſhing quality; but no fermenting liquors can be prudently allowed till the deſquamation of the cuticle is ſomewhat advanced.

In order to diminiſh the pain ariſing from the irritation of the ſkin, the warm bath may be uſed as often as the patient's ſtrength will permit. His linen and ſheets, which are ſoon rendered hard and ſtiff by the diſcharge, ſhould be very frequently changed. Mr. Pearſon is alſo in the habit of covering every part, where excoriations occur, with a ſoft mild cerate, made of litharge plaſter, yellow wax, and olive oil. This application is to be thickly ſpread on rollers, by which means it may be conveniently put wherever it is needed. The dreſſing ſhould be changed twice a day.

Dr. M'Mullin has noticed, that, though in the early ſtage of the mercurial erythema, diaphoretics are indicated, yet the bowels are ſo irritable, that ſuch medicines can ſcarcely be employed. For the ſame reaſon, he recommends us to be very cautious in giving mineral acids, ripe fruits, &c. This gentleman approves of the patient being kept in rather a warm temperature, and in a place where he can derive the advantage of a quick circulation of air. The bowels being weak, Dr. M'Mullin adviſes us only to employ the mildeſt purgatives, when medicines of this claſs are required.

With regard to the topical treatment, the latter gentleman ſays, that ſolutions of ſulphate of zinc, and acetite of lead, ſulphur ointment, and the decoction of oak-bark, have all been tried, but without any particular good, and he ſeems to prefer ſprinkling the parts with powdered ſtarch. To allay the cough and ſoreneſs of the fauces, he adviſes mucilaginous mixtures, containing a ſmall proportion of opium.

When the incruſtations become general, the fever always aſſumes more of the typhoid type. In this ſtage bark has been uſually preſcribed, with a view of ſupporting the ſtrength; but Dr. M'Mullin remarks, that this medicine can never be given in ſufficient quantity, owing to its affecting the ſtomach, or occaſioning diarrhœa. In ſome inſtances, he obſerves, the cold infuſion, conjoined with aromatics, has been beſt retained, and a little opium may be added to the doſes. Opium, which this gentleman deſcribes as improper in the firſt ſtage, may now be taken without any riſk of unpleaſant conſequences. He ſtates, that wine is the beſt remedy in this ſtage of the diſeaſe. Porter and diluted ſpirit are alſo proper, and the thirſt muſt be aſſuaged with whey, light broths, and nouriſhing drinks of every kind. Owing to there being now a large extent of the ſkin in an excoriated ſtate, the patient cannot at this time generally bear warm bathing, which often brings on a ſtate of ſyncope, and all that can be done is to waſh the parts, in the moſt tender manner, with tepid water.

For the ophthalmia tarſi, the unguentum zinci vitriolati is recommended, and the linimentum aquæ calcis is ſaid to relieve moſt effectually the pain which makes the patient feel as if his fleſh were cracking.

We ſhall conclude this article with adviſing the reader, who wiſhes to be perfectly acquainted with the ſubject of mercurial erythema, to conſult B. Bell's Treatiſe on Gonorrhœa Virulenta and Lues Venerea, vol. ii. p. 228. Pearſon on the Effects of various Articles in the Cure of Lues Venerea. Edit. 2. p. 165. An Eſſay on a Peculiar Eruptive Diſeaſe ariſing from the Exhibition of Mercury, by G. Alley, Dublin, 1804. A Deſcription of the Mercurial Lepra, by Dr. Moriarty, Dublin, 1804. Hiſtory of Three Caſes of Erythema Mercuriale, by Dr. Spens, in Edinb. Med. and Surgical Journal, vol. i. p. 7. Eſſay on Erythema Mercuriale, by Dr. M'Mullin, in Edinb. Med. and Surgical Journal, vol. ii. p. 25. Caſe of Erythema not occaſioned by Mercury, by John Rutter, M. D. in Edinb. Med. and Surgical Journal. vol. v. p. 143.

ERYTHRÆ, in *Ancient Geography*, a town of Greece, in Bœotia. Pliny. It was ſituated near mount Citheron, according to Euripides. Some authors place it in the territory of Platæa, to the eaſt of this town.—Alſo, a town of Greece, in Theſſaly, ſituated upon the river Erypæus, according to Strabo.—Alſo, a town of Greece, in Œtolia, near Eupalium.—Alſo, a town in the iſle of Cyprus, called Paphos.—Alſo, one of the twelve towns of Aſia Minor, in Ionia, according to Pliny Strabo ſays, that it gave name to the Erythræan Sibyl. He ſays alſo, that it had a port, called Cyſſus, in which were four iſles called Hippi. This town was built by Nilæus, the ſon of Codrus. In the town was a temple of Hercules, one of the moſt ſtately edifices in all Aſia. Erythræ took part, on all occaſions, with the Romans, who rewarded its fidelity with ample privileges, and conſiderably enlarged its territory. It is now a village, named Erethri.—Alſo, a town of Africa, in Libya.

ERYTHRÆA, in *Botany*, ερυθραια, *red*, a name given by Renealm to the *Chironia Centaurium*, (Gentiana *Centaurium* of Linnæus), on account of its red colour, unuſual in the Gentian tribe. This writer controverts the univerſally received opinion of its being the κενταυριον μικρον of Dioſcorides, becauſe the latter is ſaid to prefer watery ſituations. But neither this, nor indeed any other of his arguments, is of much weight; for the *Chironia Centaurium* often occurs in low and wet places, and according to Dr. Sibthorp is very frequent throughout Greece. *Chironia ſpicata*, which Dioſcorides would hardly diſtinguiſh from it always grows in marſhy ſpots, and is found on the coaſts of Greece, as may alſo *Chironia pulchella*, though ſcarcely diſtinguiſhed by any body from the common kind when Dr. Sibthorp viſited that country, and therefore not noted by him.

ERYTHRÆAN Sea, in *Ancient Geography*, is the ancient name of the *Red Sea*. Indeed, the ancients gave this name to the whole expanſe of water that extends from the coaſt of Ethiopia to the iſland of Taprobana. This appellation was probably derived from Edom or Eſau, whoſe deſcendants were called Idumæans, and inhabited the northern part of Arabia. The Idumæans navigated upon the Red ſea and the Perſian gulf, and alſo upon the Indian ſea, and the oriental name Idumæan ſignified red. Whence the ſea of the Idumæans was called the Red ſea, and the Erythræan ſea.

ERYTHRÆAN *Sibyl*. See SIBYL.

ERYTHREAN, an appellation given to Hercules, from a temple which he had at Erythres, in Arcadia.

ERYTHRINA, in *Botany*, from ερυθρος, *red*, on account of the ſcarlet flowers, whence alſo it is called Coral-tree. Linn. Gen. 365. Schreb. 486. Willd. Sp. Pl. v. 3. 912. Mart. Mill. Dict. v. 2. Juſſ. 356. (Corallodendron; Tournef. t. 446.) Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, entire, tubular; its margin more or leſs two-lobed; its baſe on the lower ſide furniſhed with a honey-bearing pore. *Cor.* papilionaceous, generally of five petals; ſtandard much the longeſt, lanceolate, aſcending, its ſides bent downwards; wings minute, ſomewhat ovate, ſcarcely longer than the calyx, and hardly reaching beyond the claw of the ſtandard; keel ſtraightiſh, uſually about the length of the wings, ſometimes longer, of two petals either ſeparate or united, notched at the end. *Stam.* Filaments ten, unequal, united below into a tube, ſlit at the upper edge, a little incurved, half as long as the ſtandard, one of them occaſionally ſeparate; anthers ten, oblong. *Piſt.* Germen ſuperior, ſtalked, awl-ſhaped, tapering into an awl-ſhaped ſtyle, as long as the ſtamens; ſtigma terminal, ſimple. *Peric.* Legume very long, protuberant from the ſeeds, pointed, of one cell. *Seeds* ſeveral, kidney-ſhaped.

Eſſ. Ch. Calyx two-lobed, ſtandard much longer than the keel. Wings minute. Legume cylindrical, with many convex ſeeds.

Obſ. *E. herbacea* has the tenth ſtamen ſeparate; which is alſo the caſe with *E. Criſta-galli*, whoſe keel moreover has its petals united into one, and is much longer than in the generality of the ſpecies.

The ſpecies of this ſplendid genus are, for the moſt part, natives of very hot climates in the Eaſt or Weſt Indies, and amount in Willdenow, who has paid particular attention to them, and deſcribed two new ones, to twelve.

E. *herbacea*, Linn. Sp. Pl. 992. Trew. Ehret. t. 58. found in Carolina, will ſupport our winters in a green-houſe, nor does its ſtem always die down to the root. The *flowers* form long and very handſome ſpikes, being of a moſt vivid though deep ſcarlet, with purpliſh ſtalks and calyx. *Seeds* ſcarlet with a black eye.

E. *Corallodendrum*, Linn. Sp. Pl. 992, brought from the Weſt Indies, requires a ſtove. It has an arboreſcent prickly *ſtem*, with *flowers* much like the former.

E. *mitis*, Jacq. Hort. Schoenbr. v. 2. 47. t. 216, is another ſimilar ſpecies in its *flowers*, but deſtitute of prickles. It was ſent to the Imperial garden from the Caraccas.

E. *Criſta-galli*, Linn. Mant. 99. Sm. Exot. Bot. v. 2. 69. t. 95, is perhaps one of the moſt ſtately of the whole. This is ſaid to be a native of Braſil, but was raiſed in the Liverpool garden from ſeeds brought from the Eaſt Indies, probably from the garden at Calcutta. It was in 1805 but a ſlender prickly ſhrub about ſix feet high, with ternate prickly-ribbed *leaves*. *Flowers* in large terminal cluſters, of a rich unpoliſhed deep ſcarlet, their ſtandards much broader, and keels much longer, than is uſual in this genus; the wings very ſmall and three-lobed, of a greeniſh white. Tenth *filament* ſeparate to the very baſe.

E. *ſpecioſa*, Andr. Repoſ. t. 443, a plant we have never ſeen, flowered in the garden of A. B. Lambert, eſq., and though ſuppoſed to be a native of South America, is ſaid to be perfectly hardy, and to ſtrike very freely from cuttings. Whether it be comprehended under any of Willdenow's ſpecies, we are not at all certain. The *ſtem* is prickly, thick and ſtrong. *Leaflets* very broad, with prickly ribs. *Flowers* ſcarlet, in very denſe ſpikes. *Wings* half as long as the ſtandard, which is narrow like the firſt ſpecies; keel not half ſo long as the wings. If theſe circumſtances are conſtant, the generic character will require correction.

ERYTHRINUS, in *Ichthyology*, a ſpecies of SPARUS and alſo of SALMO, which ſee reſpectively.

ERYTHROCEANEUS, in *Ornithology*, the red and blue maccaw, with a wedge-like tail, and the ſides of the head naked and rough. See PSITTACUS.

ERYTHRODANUM, in the *Materia Medica*, a name by which ſome authors have called the rubia tinctorum, or madder.

ERYTHROIDES, in *Anatomy*, from ερυθρος, *red*, and ειδος, *form*, a name given by ſome anatomiſts to the firſt proper covering of the teſticles. It is not now admitted that theſe bodies are covered by any thing except the fibres of the cremaſter and cellular ſubſtance of the ſcrotum, to which, perhaps, the above-mentioned name may have been applied.

ERYTHRONIUM, in *Botany*, from ερυθρος, *red*, in alluſion either to the colour of the flower, or to the more unuſual blood-like ſtain in the leaves. Dog's-tooth Violet. Linn. Gen. 165. Schreb. 220. Willd. Sp. Pl. v. 2. 96. Mart. Mill. Dict. v. 2. Juſſ. 48. (Dens canis; Tournef. t. 202.) Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Liliа*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals ſix, regular, lanceolate, pointed, lying over one another alternately towards the baſe, ſpreading gradually, reflexed from about the middle; three of them external, three internal. Nectary two ſcars, or little ſcales, at the baſe of each of the inner petals. *Stam.* Filaments ſix, uniform, awl-ſhaped, ſhort; anthers oblong, erect, as long as the filaments. *Piſt.* Germen ſuperior, roundiſh or oblong, with three angles; ſtyle ſimple, ſhorter than the corolla, taper at the baſe, and a little bent at that part, otherwiſe ſtraight; ſtigmas three, ſpreading, ſomewhat cylindrical, furrowed, or notched. *Peric.* Capſule nearly globular, contracted at the baſe, of three cells and three valves. *Seeds* numerous, ovate, pointed.

Eſſ. Ch. Corolla bell-ſhaped, of ſix reflexed petals. Nectary two ſcars at the baſe of the three inner ones. Capſule globoſe, contracted at the bottom. Seeds ovate.

1. E. *Dens canis*. Linn. Sp. 437. Jacq. Auſtr. v. 5. 31. append. t. 9. Curt. Mag. t 5. Leaves with a blunt flat point. Style cylindrical. Germen globoſe, obtuſe. Native of mountainous places in Italy, Switzerland, Carniola, Styria, Carinthia and Tartary, flowering in the ſpring. In our gardens it is a hardy perennial, diſtinguiſhed by its elliptical radical *leaves*, very various in breadth, elegantly ſtained with purple, and its ſolitary drooping crimſon or whitiſh *flower*, with pendulous dark purple anthers. No remains of the herbage are to be ſeen after the end of June. Lobel and ſeveral botaniſts of his time preſumed this to be the real ςατυριον of Dioſcorides, nor does it ill accord with the deſcription, though Dr. Sibthorp ſeems not to have met with the plant in Greece. It cannot, however, be made to agree with the ςατυριον ερυθρονιον of the ſame author, though the latter appellation ſeems to have given riſe to its preſent generic name. The old authors made two ſpecies on account of the various dimenſions of the leaves, which Linnæus reduced to one, but he very improperly made a third variety of the following ſpecies.

2. E. *flavum*. (E. americanum; Curt. Mag. t. 1113. E. Dens canis γ; Linn. Sp. Pl. 437.) Leaves involute at the point. Style club-ſhaped. Native of the colder parts of North America. It flowered in April 1808, in the gardens of Mr. Loddiges at Hackney, and Mr. Saliſbury at Brompton, and was firſt well determined by Mr. Gawler in Curtis's Mag. The leaves reſemble the former, except in having a hooded termination, from the involute edges of the point. *Flower* deep yellow ſpotted with red. *Anthers* and pollen yellow. *Style* very thick in the upper half. *Germen* obovate.

3. E. *revolutum*. Leaves flat-pointed? Style cylindrical. Germen elliptic-oblong, acute.—Gathered by Mr. A. Menzies on the weſt coaſt of North America. The *leaves* are broadly elliptical, and in our ſpecimens appear pale, and ſcarcely ſpotted. *Petals* purpliſh, very much rolled back, as in the Martagon Lily. *Stamens* with unuſually long taper-pointed filaments, and pale or yellowiſh, not dark purple, anthers. *Germen* elliptic-lanceolate, pointed. *Style* contracted at the baſe, but otherwiſe pretty exactly cylindrical, with much longer ſtigmas than either of the foregoing.—The whole plant alſo is larger, and appears to us unqueſtionably diſtinct. The diſcovery of this ſpecies in America renders the original name of the laſt ſo exceptionable, that we hope we may be pardoned for changing it before it is adopted in any regular ſynoptical work, otherwiſe it would be too late. S.

ERYTHROPHTHALMUS, in *Ichthyology*. See CYPRINUS.

ERYTHRORHIZA, in *Botany*, ερυθρα ῥιζα, *a red root*; Michaux Fl. Boreali-Amer. v. 2. 36. t. 36, is *Galax aphylla*, which ſee.

ERYTHROXYLUM, ερυθρον ξυλον, *red wood*. Brown. Jam. 278. Linn. Gen. 228. Schreb. 307. Willd. Sp. Pl. v. 2. 746. Mart. Mill. Dict. v. 2. Juſſ. 253. Claſs and order, *Decandria Trigynia*. Nat. Ord. *Tribilatæ*, Linn. *Malpighiæ*, Juſſ.

Gen Ch. *Cal.* Perianth of one leaf, turbinate, very ſmall, withering, in five ovate acute ſegments. *Cor.* Petals five, ovate, concave, ſpreading. Nectary an upright, coloured, notched ſcale, attached to the baſe of each petal. *Stam.* Filaments 10, the length of the corolla, connected at the baſe by an abrupt membrane; anthers heart-ſhaped. *Piſt.* Germen ovate, ſuperior; ſtyles three, thread-ſhaped, diſtant, the length of the ſtamens; ſtigmas thickiſh and obtuſe. *Peric.* Drupa ovate, of one cell. *Seed.* Nut oblong, with four obtuſe angles.

Eſſ. Ch. Calyx turbinate. Petals five, each with a notched nectariferous ſcale at its baſe. Stamens connected at their baſe. Drupa of one cell.

This genus, founded by Browne, conſiſts of two ſpecies only in his work. 1. *E. areolatum*, Linn. Sp. Pl. 612. Brown. Jam. t. 38. f. 2. and t. 14. f. 3. (E. carthaginenſe; Jacq. Amer. 134. t. 87. f. 1.) This is called, in Jamaica, Red Wood, or Iron Wood, and is ſaid to be excellent for the ſize of the tree, which is not above five or ſix inches in diameter. The *leaves* are obovate, two inches long, marked with two lines at the back, which circumſcribe the part that was expoſed before each leaf expanded. *Flowers* ſtarry, white, fragrant, on ſimple, cluſtered, lateral ſtalks.

2. The ſecond ſpecies of Browne has been neglected by following authors, probably as a variety of the firſt. He deſcribes it as different in its manner of growth, with ſmaller rounder *leaves*.

Cavanilles and Lamarck have much increaſed the number of ſpecies, ſo that they now amount in Willdenow's work to 12, all except the above unknown to Linnæus. They are natives either of South America, Madagaſcar, or the iſlands of Mauritius and Bourbon, and were chiefly gathered by Commerſon. The French call many of them Bois d'huile. The wood is, in ſome inſtances, ſaid to have a very ſtrong and diſagreeable ſmell while burning.

ERYX, in *Ancient Geography*. See Erix.

Eryx, in *Zoology*, a ſpecies of Anguis, being the *Anguis dorſo trilineato* of Boddaert, above cinereous, with three black lines, and light blueiſh beneath. It is found in England, and in America.

ERZ, or Erzi, in the *Botanical Writings of the Ancients*, a word uſed originally by the Hebrews, and by them made the name of the cedar.

ERZEN, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, ſeated on the Humme; 7 miles S.W. of Hameln.

ERZERUM, or Arzerum, a city of Aſiatic Turkey, and capital of a pachalic to which it gives name, and is a part of Armenia, ſituated near the head of the Euphrates, at the foot of a chain of mountains which are uſually covered with ſnow till the latter end of ſpring. The town is ſurrounded with a double wall, and defended with ſome ſquare towers; the houſes are mean, and none of them large. The ſuburbs are inhabited by Chriſtians. Of the inhabitants, they count 18,000 Turks, of whom two-thirds are Janizaries; 6000 Armenians, who have an archbiſhop, and two churches; and 400 Greeks, who have a biſhop, and one mean church. The Greeks are moſtly employed in the manufacture of copper, brought from ſome mines three days journey from the city; this, and the manufacture of the ſkin of a ſpecies of martin, are the only articles of their commerce. Erzerum is the ſtaple of the merchandize of India, eſpecially when the Arabians infeſt the environs of Aleppo and Bagdad. This merchandize conſiſts of ſilk from Perſia, cotton, painted linens, ſpices, rhubarb from Bucharia, madder from Perſia, zedoary, &c. This town was one of the laſt which was taken from the Greek emperors by the Arabians; 250 miles N.N.E. of Aleppo, and 510 E. of Conſtantinople.

ERZGEBIRG. See Ertzgebirge.

ESAPHE, from εσαφαω, *I feel with the fingers*, a word uſed by Hippocrates, to expreſs the touching of the mouth of the uterus, in order to diſcover its ſtate of diſeaſe.

ESAU, in *Biography*, the ſon of Iſaac and Rebecca, and the twin-brother of Jacob, whom he ſucceeded at his birth, was born in the year 1836 B.C. At his birth he was covered with hair, indicating great bodily ſtrength, by which he was fitted for the kind of life to which he afterwards devoted himſelf. As he was fond of hunting, he ſupplied his father with a variety of delicious food, and became his favourite. Jacob, however, was the favourite of his mother, and by means of a circumſtance mentioned in his hiſtory, ſupplanted Eſau of his birth-right, which he conſented to barter for a meſs of red pottage, that had been prepared for their father, during his abſence. Hence he and his poſterity derived the appellation of Edom, ſignifying red. At the age of 40 years Eſau diſtreſſed his parents by marrying two wives out of idolatrous Canaanitiſh families, with which the poſterity of Abraham were prohibited from forming any connection. In proceſs of time, he regained his father's favour, and as death approached, Iſaac determined to confer his laſt prophetic benediction on Eſau, as his firſt-born ſon and heir. The artifice of his mother, however, counteracted his purpoſe; and ſhe contrived to impoſe upon Iſaac, and to obtain the father's parental bleſſing for her ſon Jacob. Eſau was indignant on account of the treatment of his brother; and determined to kill him as ſoon as their father ſhould die.

Rebecca again interpoſed, and ſent Jacob away to her brother Laban, with whom he might be ſecure from the threatened vengeance of his brother. During the period of ſeparation, which laſted ſeveral years, Eſau married a wife of the family of Iſhmael, and removing to mount Seir, acquired great power and wealth. When Jacob returned, after long abſence, to his father's country, with a numerous family, and large flocks and herds, he dreaded his brother's diſpleaſure; and though they had an amicable and affectionate interview, he entertained ſuſpicion of remaining reſentment, and inſtead of complying with the wiſhes of his brother, who was deſirous that he would ſettle in his neighbourhood, he dwelt in Shechem. After their father's death they lived in peace and amity; but as their poſſeſſions enlarged, and there was not ſufficient room for them in the land in which they were ſtrangers, Eſau returned to mount Seir, where his poſterity multiplied under the denomination of Edomites. (See Edom.) The time of his death is not mentioned, but biſhop Cumberland thinks it probable that he died about the ſame time with his brother Jacob, at the age of about 147 years. Geneſis, ch. xxv—xxxvi.

Esau, in *Geography*, a mountain of Arabia, in the country of Yemen, 4 miles N. of Udden.

ESAULOVO, a town of Ruſſian Siberia, in the government of Kolivan; 36 miles E.S.E. of Kraſanoiarſk.

ESBONITÆ, in *Ancient Geography*, a people of Arabia Petræa, who took their name from the capital, which was ſeated in the mountains over-againſt Jericho.

ESBUS. See Heshbon.

ESCACENA, in *Geography*, a town of Spain, in the country of Seville; 20 miles W. of Seville.

ESCAILLON, a river of France, which runs into the Scheldt, about two miles above Valenciennes.

ESCALA, La, a town of Spain, in the province of Catalonia, on the coaſt of the Mediterranean; 22 miles E. of Gerona.

ESCALADE, or Scalade, in the *Military Art*, a furious attack of a wall or a rampart; carried on with ladders, to paſs the ditch, or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to ſecure the men.

When the troops are prepared to paſs the ditch, either with the aſſiſtance of boards, hurdles, and faſcines, when it is muddy, or with ſmall boats of tin, or baſkets covered with ſkins, or oil-cloth when it is deep, and filled with water, a party muſt be placed on the counterſcarp, oppoſite to the landing-place, ready to fire at the garriſon if they are alarmed, and oppoſe the mounting on the rampart. If the ditch is dry, the ladders are fixed in ſome place fartheſt diſtant from the centry; and as ſoon as they get upon the rampart, they put themſelves in order to receive the enemy; if the centry ſhould be ſurpriſed, and ſilently overcome, the detachment haſtens to break open the gate, and to let in the reſt of the party. If the ditch is wet, the rampart high, and provided with a revetement, it will be difficult to ſurpriſe the town in this way; but if there is no revetement, the troops may hide themſelves along the outſide of the rampart till all are over. Since the invention and uſe of gun-powder, and the walls of cities have been flanked, they are ſeldom taken by eſcalade.

ESCALANA, in *Geography*, a town of Spain, in Old Caſtile; 14 miles N.N.E. of Segovia.

ESCALANTE, a town of Spain, in the province of Biſcay; 15 miles E. of Santander.

ESCALAON, a town of Portugal, in the province of Beira; 16 miles N. of Almeida.

ESCALLION, in *Botany*. See SCALLION.

ESCALLONIA, ſo called by the younger Linnæus, at the recommendation of Mutis, in honour of a learned Spaniard named Eſcallon, the pupil of Mutis in botany, mathematics and philoſophy, and his inſeparable companion during his abode in New Spain. This gentleman diſcovered the ſhrub in queſtion, as well as a vaſt number of new or rare plants beſides, in his various journeys through New Granada, moſt of which were, by Mutis or himſelf, communicated to Linnæus or his ſon. A very fine plant was originally choſen by Mutis for the above purpoſe, of which a ſpecimen and drawing were ſent to Linnæus; but it proved, on a careful examination, to be a *Loranthus*, and remains undeſcribed in the Linnæan herbarium. —Linn. Suppl. 21. Schreb. 152. Willd. Sp. Pl. v. 1. 1149. Mart. Mill. Dict. v. 2. Juſſ. 321. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Onagræ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, inferior, hemiſpherical, with five large, ſpreading, ovate, acute, permanent teeth. *Cor.* Petals five, equal, inſerted into the calyx, tongue-ſhaped or obovate, obtuſe, a little diſtant from each other, longer than the calyx-teeth. *Stam.* Filaments five, equal, erect, awl-ſhaped, inſerted into the calyx between the petals, oppoſite to its teeth and about the ſame length; anthers incumbent. *Piſt.* Germen half inveſted with the calyx, globular; ſtyle cylindrical, ſtraight, the length of the ſtamens; ſtigma capitate, umbilicate. *Peric.* Berry roundiſh, of two cells, crowned with the calyx-teeth. *Seeds* very numerous, minute.

Eſſ. Ch. Berry of two cells, with many ſeeds. Calyx encompaſſing the fruit. Stigma capitate. Petals five, inſerted into the calyx.

1. E. *myrtilloides*. Linn. Suppl. 156. Sm. Pl. Ic. t. 30. —Leaves finely ſerrated, minutely pointed, veiny beneath. Flowers ſolitary.—Gathered in New Granada by Eſcallon. —*Stem* ſhrubby, branched, ſlightly angular, with a ſmooth deciduous bark. *Young branches* numerous, alternate, ſhort, ſimple, leafy, each terminated by a ſolitary, ſtalked, terminal *flower*. *Leaves* alternate, ſpreading, about three-quarters of an inch long, obovate, obtuſe with a minute point, minutely ſerrated, eſpecially towards the end, ſmooth, deciduous; with no perceptible veins on the upper ſide; paler and veiny beneath; the baſe tapering down into a ſhort, often fringed, *footſtalk*, each of whoſe edges unites at their baſe with a glandular toothed angle or rib in the branch. *Stipulas* none. *Flower-ſtalks* angular and glandular. *Petals* about thrice as long as the calyx-teeth, apparently white, erect, their extremities reflexed. *Berry* black? the ſize of a large pea, or bigger, crowned with the calyx and baſe of the ſtyle.

2. E. *ſerrata*. Sm. Pl. Ic. t. 31.—Leaves ſerrated, ſomewhat abrupt, ſmooth and without veins at the back. Flowers ſolitary.—Gathered about the ſtraits of Magellan, by Commerſon; in Staten land, (not Terra del Fuego,) by Mr. Archibald Menzies.—A humble branched ſmooth *ſhrub*, with ſomething of the aſpect of a *Vaccinium*. *Branches* alternate, ſomewhat zig-zag, angular, with a pale ſmooth bark; thoſe of the preſent ſeaſon green, leafy, ſtraighter, each bearing a ſolitary, terminal, ſtalked flower. *Leaves* deciduous, alternate, obovate, obtuſe, often abrupt or retuſe, with a minute central point or tooth, equally ſerrated or ſomewhat crenate, very ſmooth; ſlightly veiny above; pale and deſtitute of lateral veins beneath, though furniſhed like the former with a ſtrong central rib. *Footſtalks* ſmooth and entire, as are the angles of the branches. *Stipulas* none. *Flower-ſtalk* ſmooth. *Petals* white, ſpreading, not recurved. Top of the *germen* violet. All the parts of fructification, except the petals, are but one-third the ſize of the former. The little *berries*, crowned with the permanent ſtyle, appear to remain through the winter, and their upper part, above the calyx-teeth, eaſily ſeparates like a lid as they ripen, expoſing the pulp full of ſmall ſeeds, with its tranſverſe partition.

3. E. *glanduloſa*. Leaves double ſerrated, acute, glandular at the back like the branches. Flowers ſomewhat corymboſe.—Gathered in Chili by Mr. A. Menzies.—*Branches* wand-like, roundiſh, leafy, when young clothed with abundance of prominent glandular tubercles. *Leaves* alternate, when full grown near an inch and half long, obovate, pointed, ſtrongly and doubly ſerrated; ſmooth or ſlightly downy above; veiny, and rough with innumerable prominent reſinous glands, beneath; tapering at the baſe into a ſhortiſh glandular *footſtalk*. Each leaf is accompanied by an axillary tuft of ſmaller ones, the rudiments of future branches. *Stipulas* none. *Flower-ſtalks* ſeveral about the tops of the branches, axillary and terminal, ſimple or ſubdivided, each about an inch long, angular, glandular like the branches, as is alſo the baſe of the calyx. *Bracteas* few, at the baſe or ſubdiviſion of each ſtalk, linear, glandular. *Calyx* about the ſize of the laſt. *Petals* more like the former, and ſomewhat longer, with rounded, reflexed extremities. *Style* furrowed, ſurrounded at its baſe with an annular lobed gland or nectary, of which we can find no traces in the other ſpecies. *Germen* of two cells. The *fruit* we have not ſeen. S.

ESCALONA, in *Geography*, a ſmall, tolerably built, walled town of Spain, in the province of New Caſtile, with ſeveral ſuburbs, ſeated on an eminence defended by a caſtle, in a fruitful ſpot watered by the Alberche, 20 miles N.W. of Toledo, and 32 S.W. of Madrid. It has four churches, and two convents.

ESCALOP *Foſſil Shells*, in *Conchology*, are deſcribed by Da Coſta (Conchol. p. 247.) as found in the lime-ſtone quarries at Thame in Oxfordſhire; Mr. Walcot, in his "Petrifactions found near Bath," has alſo deſcribed a ſimilar kind of ſhell, as found in the clay on the ſide of the road between Claverton-Down and village, and in the free-ſtone at the quarries near King's Down; and another kind found in a ſlaty loam at the limeſtone quarry near the Creſcent in Bath.

ESCAMBIA, one of the moſt conſiderable rivers that fall into the bay of Penſacola, in Weſt Florida, diſcharges itſelf near the head of the north branch, about 12 or 15 miles from Penſacola, through ſeveral marſhes and channels which have a number of iſlands between them, that are overflowed when the water is high. The courſe of this river from an unknown ſource is very winding. The lands on each ſide are, in general, rich, low, or ſwampy, or well adapted for the culture of rice or corn. The numerous rivulets that fall into this river from the high country about it may be led over every part of the rice lands, at any ſeaſon of the year. The iſlands at the mouth of the river, of which ſome are conſiderable in extent, are not inferior for rice to any in America.

ESCAMBIO, from the Spaniſh *cambier*, to change, was anciently a licence granted any one for making a remittance, or giving a bill of exchange to another, beyond ſea.

For, by ſtat. 5 Rich. II. no perſon might exchange, or return money beyond ſea, without the king's licence

ESCAMUS, in *Ancient Geography*, a river of Mœſia, which has its ſource in mount Hæmus.

ESCAPE, FIRE. See FIRE-ESCAPE.

ESCAPE, in *Law*, an evaſion out of ſome lawful reſtraint, either by violence or ſtealth.

Eſcapes are either *voluntary*, or *negligent*.

Voluntary, are ſuch as are, by the expreſs conſent of the keeper to whoſe cuſtody, in civil actions, the debtor has been committed; after which, he can never retake his priſoner again, (3 Rep. 52. 1 Sid. 330.) though the plaintiff may retake him at any time, (ſtat. 8 or 9 W. III. c. 27.); but the ſheriff muſt anſwer for the debt.

Negligent eſcapes are where the priſoner eſcapes without his keeper's knowledge or conſent; and then upon freſh purſuit the defendant may be retaken, and the ſheriff ſhall be excuſed, if he has him again before any action brought againſt himſelf for the eſcape. (F. N. B. 130.) A reſcue of a priſoner in *execution*, (which ſee,) either going to gaol or in gaol, or a breach of priſon will not excuſe the ſheriff from being guilty of and anſwering for the eſcape; for he ought to have ſufficient force to keep him, ſince he may command the power of the county (Cro. Jac. 419.)

An eſcape of a perſon arreſted upon criminal proceſs, by eluding the vigilance of his keepers before he is put in hold, is an offence againſt public juſtice; and the party himſelf is puniſhable by fine or impriſonment. (2 Hawk. P. C. c. 122.) But the officer permitting ſuch eſcape, either by negligence or connivance, is much more culpable than the priſoner. Officers, therefore, who, after arreſt, *negligently* permit a felon to eſcape, are puniſhable by fine (1 Hal. P. C. 600.); but *voluntary* eſcapes, by conſent and connivance of the officer, are a much more ſerious offence; for it is generally agreed that ſuch eſcapes amount to the ſame kind of offence, and are puniſhable in the ſame degree, as the offence of which the priſoner is guilty, and for which he is in cuſtody, whether treaſon, felony, or treſpaſs; and this, whether he was actually committed to gaol, or only under a bare arreſt. (1 Hal. P. C. 590. 2 Hawk. P. C. 124.) But the officer cannot be thus puniſhed, till the original delinquent hath actually received judgment or been attainted, upon verdict, confeſſion, or outlawry, of the crime for which he was ſo committed or arreſted; otherwiſe it might happen, that the officer might be puniſhed for treaſon or felony, and the perſon arreſted, and eſcaping, might turn out to be an innocent man. But before the conviction of the principal party, the officer thus neglecting his duty may be fined and impriſoned for a miſdemeanor. (1 Hal. P. C. 588, 9. 2 Hawk. P. C. 134, 5.). See RESCUE.

ESCAPE *warrant*. If any perſon committed or charged in cuſtody in the king's bench, or Fleet priſon, in execution, or on meſne proceſs, &c. go at large; on oath thereof before a judge of the court where the action was brought, an eſcape warrant ſhall be granted, directed to all ſheriffs, &c. throughout England, to retake the priſoner, and commit him to gaol when taken, there to remain until the debt is ſatisfied; and a perſon may be taken on a Sunday upon an eſcape warrant. Stat. 1 Anne, cap. 6.

ESCAPEMENT, in *Horology*, is an ingenious mechanical contrivance for tranſmitting, in a modified way, and at equidiſtant intervals of time, the maintaining power of a clock or watch to the regulator, whether balance or pendulum, in order to reſtore that loſs of motion in every vibration or oſcillation, which neceſſarily ariſes from the friction of the acting parts, and the reſiſtance of the air in every machine. It has been ſaid, under the article CLOCK, that the maintaining power, whether conſiſting of a weight or ſpring, when ſuffered to expend itſelf unreſtrained, would make the wheel-work run on with an increaſing velocity, until the obſtacles to motion, ſuch as the friction in the teeth and at the pivots, the reſiſtance of the air, &c. fixed the maximum of velocity with which it could expend itſelf; at which period the friction and reſiſtance would jointly operate as a regulator, whilſt they and the maintaining power remained unaltered, and the machine ſo circumſtanced would greatly reſemble a common kitchen-jack; and if an index were inſerted on the arbor of the firſt or ſlowly moving wheel, it would indicate ſuch portions of time as the ratio between the maintaining power and the regulating friction and reſiſtance of the air taken together would produce; but it is obvious, that every alteration produced in the friction by wear, foulneſs, &c. or in the denſity of the air by the ſtate of the atmoſphere, would affect the indication ſo much, as to render it extremely irregular; hence the balance and the pendulum were ſucceſſively invented and applied to regulate the indication of time by their iſochronous vibrations; but then as both theſe regulators have alternate motions backwards and forwards, they could neither of them be applied *immediately* to check a wheel that moves continually in one direction, without the intervention of ſome contrivance, connected both with the wheel and regulator, which ſhould convert a direct circular motion into a motion changing its direction by perpetual alternations. To deviſe and execute a piece of mechaniſm that ſhould perform ſuch an office ſteadily and accurately, required much ſcience as well as mechanical ſkill, and the invention once executed was denominated an *eſcapement*, or by contraction among the workmen *'ſcapement*, becauſe it ſuffers a tooth of the wheel, with which it acts, to *eſcape*, or paſs on, at ſuch intervals of time as are meaſured by the regulator, which wheel is therefore alſo called the *eſcapement wheel*.

From this ſhort account of the origin and office of an eſcapement, the reader will perceive, that the accuracy of its conſtruction conſtitutes one of the moſt eſſential conſiderations in an horometrical machine, it being an indiſpenſable condition, that the ſucceſſive impulſes taken from the maintaining power through the medium of the wheel-work, and given to the regulator, ſhould be ſo modified, as to diſturb as little as poſſible the natural iſochroniſm of the regulator, or, if it do diſturb it, that it ſhould ſomehow compenſate that diſturbance. Hence it becomes neceſſary, that the workman, or mechanician, ſhould be fully acquainted with the theory of the natural iſochroniſm of his propoſed regulator, when he undertakes to deſign and execute his eſcapement; he muſt not only know how much of the maintaining power will be ſufficient to balance the loſs ſuſtained in the natural length of a vibration, by reaſon of friction and the reſiſtance of a ſtandard medium, but he muſt conſider and indeed aſcertain, by theory or experiment, or both, at what part of the arc of vibration the power muſt be applied; likewiſe how long the impulſion ſhall continue to act, and whether that action ought to be uniform, increaſing, or decreaſing in its intenſity. Theſe and ſimilar conſiderations have produced, as might be expected, a great variety of conſtructions of an eſcapement, both with regard to their external ſhape and *modus operandi.* As a good eſcapement is of the utmoſt importance in the uſeful art of clock-making, and as we have no author in the Engliſh language who has given us the different conſtructions in hiſtorical order, together with ſuch remarks as may enable the reader to judge of their reſpective excellence, we will devote ſome time to the detail of both the theory and practical conſtruction of ſuch different eſcapements as ſeem to merit a general notice.

But before we enter upon our deſcription and examination of different eſcapements of clocks and watches, as the reader has not yet had an opportunity of peruſing the article Pendulum, and as all eſcapements derive their ſhape and manner of action from the relation they bear either to the laws of its motion, or to thoſe of a moving balance, it will contribute greatly to his better underſtanding the ſubject, if we premiſe firſt ſome of the chief circumſtances which relate to the theory of a free pendulum, and to the influence that any external impulſe will have on it when applied to become the regulator of a clock; and ſecondly, if we explain the theory of a balance's motion, which we have purpoſely reſerved for this place by reaſon of its intimate connection with the eſcapement.

1. In *fig.* 1. of *Plate* XXXI. of *Horology*, let C D repreſent a *free pendulum*, or pendulum that has no weight but what is collected at the centre of oſcillation or point D, and let the arc D B repreſent a ſemi-vibration round the point C, taken as the centre of motion or point of ſuſpenſion, at which we will ſuppoſe there is no friction, then if the reſiſtance of the air and rigidity of the ſtring or rod were not to interfere, when the pendulum was once removed from its natural or perpendicular ſituation C D to B, and ſuffered to deſcend again by the ſole force of gravity, it would acquire ſuch a velocity at its loweſt point D, by means of the accelerating force of gravity, as would, under theſe circumſtances, carry it up an equal ſemi-vibration or arc D G, the increments of accelerated motion being equal in the arc B D to the decrements of retarded motion in the equal arc D G, the ſame reaſoning would apply in the returning vibration from G to B; the velocity acquired at D by the deſcent from G to D would carry the pendulum again up to B, and the conſequence would be, under ſuch *unnatural* circumſtances, if they could be effected, that there would be a perpetual alternation of vibrations of the ſame length, which would conſequently be iſochronal with reſpect to each other, ſo long as the pendulum remained of the ſame length; and ſuch a pendulum would of itſelf be a perfect time-meaſurer, and would only want a regiſter to indicate the number of its vibrations, to make it a complete regulator or chronometer: but the fact is, the friction and rigidity at the point of ſuſpenſion cannot by human art be entirely annihilated, though ingenuity can greatly diminiſh it; nor can the obſtacle to free motion ariſing from the reſiſtance of the air be removed, or even rendered uniform; hence it is found that when a pendulum is drawn aſide from its point of reſt, every ſucceeding vibration, after motion has commenced, is ſomewhat ſhorter than the preceding one, until after ſome hours have been ſpent in alternate vibrations continually ſhortening, the pendulum finds its original point of reſt; the time expended in doing this is longer in proportion to the diminution of friction, the air and other circumſtances remaining unchanged. Ferdinand Berthoud, the famous French clock-maker, made ſome experiments to aſcertain this fact, and conſtructed the knife-edge ſuſpenſion of a ſecond's pendulum, with a heavy lenticular ball, ſo free from friction, that an arc of vibration of 10° was not reduced to 15′ till $29^{h}\,46^{m}$ had elapſed; but notwithſtanding every attempt to reduce the friction, the pendulum came to reſt at laſt. From this ſhort view of the tendency of a pendulum to come to reſt after it has had a motion communicated to it, we clearly perceive the neceſſity of making ſome auxiliary additions to the natural force of gravity, in order that the pendulum may keep up the length of its original vibration in every ſucceeding one, notwithſtanding the obſtructions which continually oppoſe the operation of gravity; theſe auxiliary additions to the motion, produced by gravity only, conſtitute the operation of the maintaining power, modified by the wheel-work and eſcapement, in every pendulum clock; and hence ariſes a *diſturbance* in the *theory* of the free pendulum, which makes ſuch a theory no farther of uſe in clock-work, than as it affords certain laws and a ſcale of forces, ſuch as the mechanician may labour to imitate, by modifying the joint agency of his *auxiliary additions* and of the operation of gravity, ſo that they ſhall act in concert; which imitation is to be effected principally, as to its *mode*, by the eſcapement, the maintaining power being concerned only as to the *quantity* of any additional power to be applied in aid of gravity.—Now, if we ſuppoſe the pendulum at the ſituation B, or extremity of its arc, and draw A B perpendicular to the vertical line C D, and B E = C B perpendicular to the line A B, or, which is the ſame thing, parallel to the line C D; alſo, if we draw B F a tangent to the arc at the point B, and from the point E demit the line E F upon it, to form a right angle at F, in which caſe the line F E will be parallel to the line C B, B E will repreſent the force of gravity, which, by the reſolution of forces, is equivalent to B F and F E; but F E is perpendicular to the tangent, or is in the direction C B of the radius, and therefore can neither accelerate nor retard the motion, whilſt B F, being in the direction of the tangent, or perpendicular to the radius, is wholly employed in accelerating or retarding the pendulum's motion: hence, the line B E : B F : : the force of gravity : the accelerating force; but from the ſimilar triangles B E F, C B A, B E is = C B, and B F = B A, therefore, by ſubſtitution, C B : B A : : force of gravity : accelerating force, and conſequently the accelerating force $= \frac{\text{gravity} \times BA,}{CB}$ in which expreſſion gravity and the radius C B are invariable, therefore the accelerating force varies as the ſine B A of the arc of vibration. From this law of variation of the accelerating force of a body moving in a circular arc, it follows, that the longer arcs require longer times than the ſhorter arcs in the proportion of 34 : 29, as Huygens has demonſtrated; for the ſine does not increaſe ſo faſt as the arc, which it ought to do, to make the vibrations of the ſame pendulum in different arcs iſochronal: if, however, the body could be made to move along the chord or ſtraight line B D, inſtead of the arc B D, then the vibrations of different lengths would be iſochronal, becauſe two ſimilar bodies will run down each a ſeparate chord of different lengths to the loweſt point of the ſame circle in the ſame time, namely, in the time that each would take in falling

through the whole diameter of the circle, and the acquired velocity of each, at the loweſt point, would be in proportion to the length of its chord. But the mechanician has not attempted to make his pendulum vibrate in chord lines, which probably is impracticable, but has invented another curve, called the cycloid, generated by a point in a circle revolving on a ſtraight line, which curve poſſeſſes this peculiar property, that the accelerating forces, which a body acquires by moving along it, are exactly proportionable to the *arcs*, (ſee Cycloid,) ſo that a pendulum vibrating in this kind of curve, will perform its long and ſhort vibrations in the ſame time. This property of the cycloid was firſt diſcovered by the celebrated Huygens, who owed much of his celebrity to it, and adopted a contrivance for making a pendulum move in ſuch a curve, which will be deſcribed under our article Pendulum, and alſo the reaſons will be given why it was laid aſide in the practice of clock-making. It may be proper, however, to remark here, that with a pendulum vibrating in the arc of a cycloid, with all its weight collected in the ball, and its length rendered invariable, if ſuch a pendulum could be made, it would, notwithſtanding, be of conſequence what the nature of the eſcapement were, becauſe though the variations in the *arcs*, ariſing from varied gravity alone, would not affect the *times* of the ſucceſſive vibrations, yet, when *additional force* is applied in aid of gravity, by means of the maintaining power and eſcapement, the uniform law of acceleration juſt deſcribed would be partially diſturbed by ſuch addition, though the diſturbance would be leſs perceptible than in circular arcs of conſiderable extent.

When, however, a pendulum vibrates in a ſmall arc, it is demonſtrable that ſuch an arc differs very little from a cycloidal arc near its loweſt point, nay almoſt coincides with it; it is alſo found from experience, that a heavy ball is leſs diſturbed by the requiſite additional force, communicated by the maintaining power, than a light one, as might be inferred from theory; on which two accounts the prevailing practice among clock-makers is, to make ſuch eſcapements for a pendulum as require but ſhort vibrations, and, in order to gain momentum, to append a heavy ball; and it has been diſcovered, and is now indeed an acknowledged fact, that a regulator with an exact compenſation for the effects of variable temperature in its pendulum, and that vibrates by means of a good eſcapement in ſmall arcs, with a heavy lenticular ball, goes with a degree of accuracy beyond what Huygens durſt even hope for from his cycloidal contrivance; in effecting which, theory and practice were found to be greatly at variance.

But the cycloidal theory, which, conſidered as a theory, is not only ingenious, but illuſtrative of the principal circumſtances which relate to the motion of a pendulum, will furniſh us with a conciſe and clear notion how the natural arc and time of a vibration will be altered by an acceſſion of external force to the force of gravity, without ſome knowledge of which alteration no mechanician can proceed on ſcientific principles in the conſtruction of an eſcapement.

Suppoſing now the pendulum in *fig.* 2, ſimilar to that in the preceding figure, and the arc to be ſo ſmall as nearly to coincide with the cycloidal curve, let the arc G B be unbent into the ſtraight line *h* H, and with the ſemi-arc D H, as a radius, deſcribe the ſemi-circle H L *h*; ſet the line A B from H to M, and from *h* to *m* perpendicular to the line *h* H, and join *m* M, which line will paſs through the centre D; from any other points I and K in the ſemi-arc or radius, draw the lines I N and K O parallel to H M, and alſo the correſponding ones *i n* and *k o* parallel to *h m*, and we ſhall obtain the following relations of the properties of the pendulum's motion, *viz.*

1ſt. The forces of gravity urging the pendulum towards D from B, at the points I and K of the ſemi-vibration, will be repreſented by, and proportional to, the ordinates I N and K O of the ſtraight line M D *m*; and the correſponding ordinates *i n* and *k o* will repreſent, and be proportional to, the retarding forces of the ſame gravity, at the points *i* and *k* of the other ſemi-vibration, and *vice verſâ* in each half of the returning vibration.

2dly. The velocities acquired by the uniform action of gravity at the points I K and *i k*, will be reſpectively proportional to the ordinates I P, K Q, and *i p*, *k q*, of the ſemicircle H L *h*; hence the velocity of the pendulum at the loweſt point D, is to its velocity at any other point of the arc I, as D L (= D H, or whole ſemi-arc) is to I P.

3dly. The times of the pendulums vibrating through the portions H I, I K, K D, &c. of its arc, will be repreſented by, and proportional to their correſponding arcs H P, P Q, Q L, &c. reſpectively in the ſemi-circle H L *h*; which proportions will be equally applicable in the aſcending portions of the arc D *k*, *k i*, and *i h*, which will alſo be moved through in times proportional to the arcs L *q*, *q p*, and *p h*, reſpectively; if the pendulum is projected from the loweſt point D with the initial velocity D L, this velocity will be reduced at the point *k* to *k q*, at *i* to *i p*, and at *h* to nothing, whence the pendulum will return, and the operation of gravity will begin to be reverſed.

4thly. If one pendulum deſcribe the arc repreſented by H D *h*, and another deſcribe the arc K D *k*, (ſtill ſuppoſing them to be cycloidal or very nearly ſo,) they will deſcribe them in equal times, but their velocities at D, or greateſt velocities, will be reſpectively proportional to H D and K D, or length of their ſemi-arcs; that is, while a pendulum, projected with the initial velocity D L, from the loweſt point, aſcends to the point *h*, or extremity of its ſemi-vibration, another ſimilar pendulum, projected with the initial velocity R D, will aſcend to the point *k*, or extremity of its arc, D R being = D *k*, and the ſame will be true in the deſcent, where the increments of motion exactly balance the aſcending decrements.

5thly. The areas M H I N, M H K O, &c. are proportional to the ſquares of the velocities acquired in moving down the arcs H I, H K, &c. or to the diminution of the ſquares of the velocities effected by the retardation of gravity in the returning or aſcending ſemi-vibration.

From a due examination of the relations exhibited in the preceding illuſtration of the principles of a pendulum's motion, the reader will readily perceive that there is a certain length of the arc of every vibration, whether performed in a circle or cycloidal curve, which correſponds to its maximum of velocity, or velocity at the loweſt point; which length, in large circular arcs, is determined by the greateſt chord line, but in cycloidal curves, or *ſmall* circular arcs, is the whole arc itſelf: he will alſo underſtand how, when the weight of a pendulum is given, its accelerating action in any given point of the arc may be appreciated; from which and ſimilar conſiderations he will be able to form ſomething like an eſtimate of the effect that will be produced in the above natural relations by the application of an external force of an aſcertained quantity, acting in a given manner: for inſtance, let us ſuppoſe that a maintaining power is applied to keep up the vibrations of a pendulum, as in our laſt figure; that the quantum of power to be added to gravity be to its accelerating force at H or *h*, as *h m* is to *m r*, which we will ſuppoſe to be a number of grains to ſome number of ounces; and that this additional power is applied through the agency of an eſcapement, which ſo modifies it, that its action is exerted but a ſhort time, and at the extremity of the arc: the rough conjecture which the reader would be apt to form would be, that as the two forces began to act in concert, a pendulum actuated by them would obey a compound ſcale of forces, differing in quantity but not in quality from the ſimple ſcale of gravity, and that therefore little or no alteration would take place in the time of its vibration; let us ſee what would be the reſult according to our theory; from the point *m* of the line *h m*, of the greateſt acceleration or retardation, as the caſe may be, ſet off *m r* equal to its repreſentative, for ſo many grains of augmenting or retarding force, and then *h r* will be the whole force urging the pendulum towards D: do the ſame for every point of *h* D, and we get a new ſcale of forces repreſented by the dotted line *r s t* D, and the ſpace *m* D *r*, contained between the two ſcales D *m* and D *r*, will repreſent the addition made to the ſquare of the velocity in moving over *h* D by the joint action of gravity and of the maintaining power. Then if we make the area D *u v* equal to the area D *h m*, by leaving out as much ſpace parallel to the perpendicular *h m*, as we take in beyond the hypothenuſe *m* D, the point *u* will limit the excurſion or extent of the returning, as well as of every ſucceeding vibration, becauſe the area of the triangle D *u v* is proportional to the ſquare of the velocity, and *u* is therefore the point where the initial velocity D L will be extinguiſhed. Laſtly, if the arc *h w* of the ſemi-circle be biſected, its half will very nearly repreſent the contraction effected in the time of the outward ſemi-vibration, agreeably both to theory and practice; and in a ſimilar manner might be eſtimated the effect to be produced on a natural vibration, or vibration from ſimple gravity, by any acceſſion of external force differently applied: in the inſtance we have given, a temporary impulſion would evidently make a greater derangement when given at the extremity of the arc, than if it had been given at I, and greater at I than at K, and conſequently the leaſt derangement would have ariſen if the impulſion had been given at the loweſt point D, which is worthy of recollection; though the fact is, that moſt of the eſcapements, that are not of the detached kind, continue to act for a ſenſible time, and, after all, the thing principally aimed at in modern practice is, to conſtruct all the parts of an horological machine ſo, that the arc of vibration may vary as little as poſſible under the different influences that affect the pendulum's motion; for then, whatever the length of the arc be, whilſt there is no variation in it, the vibrations will be iſochronal, whatever be the nature of the curve; but completely to effect ſo deſirable a purpoſe can hardly be expected under all the combinations of variable reſiſtances ariſing from friction, oil, air, &c., however detached the eſcapements may be, *i.e.* however ſmall the continuance of each of their impulſions. Hence, certain ingenious artiſts have attempted ſuch a compound ſcale of forces, conſiſting of gravity and maintaining power conjointly, as ſhall render even circular vibrations of different lengths iſochronal among themſelves, when they ſhall happen to vary in length, which plan would certainly make the beſt compenſation for the effects of variable reſiſtances, if ſuch plan could be completely executed at pleaſure; and the compound ſcale of forces to do this, muſt be to the ſcale of gravity alone, as the *arc* of ſemi-vibration is to the *ſine* of the ſame in every point of the excurſions. For in *fig.* 1, if B F be ſuppoſed equal to the ſemi-arc B D, then B E, the whole compound force at the point B, will be greater than C B or force of gravity alone, and will be to it, by ſimilar triangles, as B F (= B D) is to the ſine A B, as has been demonſtrated; therefore the whole compound force at any point B of either ſemi-vibration ſhould be to the force of gravity alone in that point, as the arc D B is to the ſine A B, which compound ſcale conſequently will demand a certain limited variation, or ſcale, in the auxiliary force derived from the maintaining power through the modifying medium of the eſcapement.

2. When a balance was firſt applied as a regulating power, it poſſeſſed no natural property, like the pendulum, of perpetuating its own oſcillations, but had its motion produced by an artificial force acting alternately on its oppoſite pallets, and derived entirely from the maintaining power at certain intervals; ſo that to perform all the oſcillations in equal times, the action of the force applied was required to be the ſame in mode, quantity, and duration, in each oſcillation, which conditions could not be fulfilled by reaſon of the conſtant changes that took place in the friction of the works, and in the denſity and conſequent reſiſtance of the air; a ſimple balance therefore was no otherwiſe better than a continued fly, except that its alternate oſcillations prevented the acceleration of motion that would enſue, if there were no ſuch frequent checks as the balance experiences at each alternate impulſe of the pallets. Dr. Hooke's invention of a regulating ſpring, to be to the natural balance what gravity is to a pendulum, was an important one, to which all the excellence of an ordinary watch may have its origin imputed, and without which the compenſations for different temperatures in the beſt chronometers would not be of any utility. The diſcovery of a *ſpring's force* being *as its tenſion*, or diſtance moved from the point of reſt, *(ut tenſio ſic vis,)* was the firſt ſtep towards a theory of motion by which the balance and its regulating ſpring, taken conjointly, may have their effect eſtimated, and by which ſuch a balance with the beſt compenſation and eſcapement now vies in accuracy even with the pendulum itſelf.—George Atwood, eſq. of Cambridge, has publiſhed an excellent memoir in the Philoſophical Tranſactions of London, vol. 84, part i. 1794, intitled "Inveſtigations founded on the Theory of motion, for determining the times of Vibration of Watch Balances," from which we beg leave to extract ſo much as falls within our purpoſe in this place.

"Let P M N S, *fig.* 3. of our laſt plate, repreſent the circumference of a watch balance, which vibrates by the action of a ſpiral (or helical) ſpring, on an axis paſſing through the centre C. Let O D B E be the circumference of a concentric circle, conſidered as fixed, to which the motion of the balance may be referred. In the circumference of this circle let any point O be aſſumed, and when the balance is in its quieſcent poſition, ſuppoſe a line to be drawn through C and O, interſecting the circumference of the balance in the point A; the radius C A will be an index, by which the poſition of the balance, and its motion through any different arcs of vibration, will be truly defined. In the ſequel, the motion of the balance, and the motion of the index C A, will be uſed indifferently, as terms conveying the ſame meaning. Since the balance is in its quieſcent poſition when the index C A is directed to the fixed point O, on this account O is called the point of quieſcence of the balance, or balance ſpring, indicating the poſition when the balance is not impelled by the ſpring's elaſtic force either in one direction or the other. If the balance ſhould be turned through any angle O C B, the ſpiral ſpring being wound through the ſame angle, endeavours by its elaſtic force to reſtore itſelf, and when at liberty, impels the balance through the arc B O with an accelerated velocity, till it arrives at the poſition O, where the force of acceleration ceaſes; with the velocity,

city acquired at O, the balance proceeds in its vibration, deſcribing the arc O E with a retarded motion. The elaſtic forces of the ſpring at equal diſtances, on the oppoſite ſides of the point O, are aſſumed to be equal; it is alſo aſſumed that the effects of friction, and other irregular reſiſtances, which retard the motion of the balance, are compenſated by the maintaining power, ſo that the time of deſcribing the firſt arc of vibration B O, by an accelerated motion, ſhall be equal to the time of deſcribing the latter arc O E, by a retarded motion, and that the entire arc of vibration B O E is biſected by the point O.

To render the conſtruction of *fig.* 3. more diſtinct, the fixed circle O D B E is repreſented to be at a ſmall diſtance from the circumference of the balance, but is to be conſidered as coincident with it, ſo that the arc B O, ſubtending the angle B C O, may be of the ſame length with an arc of the circumference of the balance, which ſubtends the ſame angle B C O: on this principle C O or C A may be taken indifferently as the radius of the balance.

The determination of the time in which the balance vibrates, from the theory of motion, requires the following particulars to be known, *viz.*

Firſt. The ſpring's elaſtic force, which impels the circumference of the balance, when it is at a given angular diſtance O D, (*fig.* 3.) from the quieſcent point O:

Secondly. The law or ratio obſerved in the variation of the ſpring's force, while the balance is impelled from the extremity of the ſemi-arc B, to the point of quieſcence O, where all acceleration ceaſes.

Thirdly. The weight of the balance, including the parts which vibrate with it.

Fourthly. The radius of the balance C O, and the diſtance of the centre of gyration from the axis of motion C G.

Fifthly. The length of the ſemi-arc B O.

Suppoſe the plane of the balance to be placed vertically, and let a weight P, (*fig.* 4.) be applied by means of a line ſuſpended freely from the circumference at T, to counterpoiſe the elaſtic force of the ſpring when the balance is wound through an angle from quieſcence O C D. This weight P (the weight of the line being allowed for,) will be the force of the ſpiral (or other) ſpring, which impels the circumference of the balance, either at reſt or in motion, when at the angular diſtance O D from the quieſcent poſition. It appears from many experiments (of Berthoud) that the weights neceſſary to counterpoiſe a ſmall ſpring's elaſtic force, when the balance is wound to the ſeveral diſtances from the quieſcent point, repreſented by the arcs O G, O H, O I, &c. *fig.* 4, are nearly in the ratio of thoſe ſeveral arcs. It alſo appears, that the ſhape, the length, and number of turns of the ſpiral, may be ſo adjuſted to each other, that the forces of elaſticity ſhall be counterpoiſed by weights, which are in the preciſe ratio of the angular diſtances from the quieſcent poſition, or, as it is ſometimes expreſſed, in the ratio of the ſpring's tenſions; at leaſt as nearly as can be aſcertained by experiment: this law of elaſtic force is aſſumed in the ſubſequent inveſtigation.

The poſition of the centre of gyration may be always determined when the figure of the vibrating body is regular, by calculating the ſum of the products, which ariſe from multiplying each particle into the ſquare of its diſtance from the axis of motion, and dividing the ſum by the weight of the vibrating body; the ſquare root of the reſult will be the diſtance of the centre of gyration from the axis of motion. When the figure of a vibrating body is irregular, recourſe muſt be had to experimental methods, in order to determine the poſition of the centre of gyration. See Atwood's treatiſe "On the Rectilinear Motion and Rotation of Bodies."

Let the radius of the balance C A or C O = r, *fig.* 3, the ſemi-arc B O = b; let the ſpring's elaſtic force, acting on the circumference of the balance, when wound to any given angle O C D, from the quieſcent poſition, be P, and let the arc O D = a; the weight of the balance and the parts which vibrate with it = W; the diſtance of the centre of gyration from the axis of motion C G = g. Theſe notations being premiſed, the reſiſtance of inertia, by which the maſs contained in the balance oppoſes the communication of motion to the circumference, is $\frac{Wg^2}{r^2}$, and conſequently the force which accelerates the circumference at the angular diſtance O C D from the quieſcent poſition is $\frac{Pr^2}{Wg^2}$. This quantity remaining invariably the ſame, while the balance deſcribes the arc of vibration B O E, may be denoted by the letter F, ſo that $F = \frac{Pr^2}{Wg^2}$; ſuppoſe the radius C A commencing a vibration from the point B to have deſcribed the arc B H, and let O H = x, ſince the force which accelerates the circumference at the angular diſtance from quieſcence O D = F, and the forces of acceleration are ſuppoſed to vary in the proportion of the angular diſtances from the quieſcent point O, the force which accelerates the circumference of the balance at the point H will be = $\frac{Fx}{a}$; let u be the ſpace through which a body falls freely from reſt by the acceleration of gravity, to acquire the velocity of the circumference at the point H; the principles of acceleration give this equation $\dot{u} = \frac{-Fx\dot{x}}{a}$; (Newtonii Princip. vol. i. prop. xxxix.) and taking the fluents while x decreaſes from b to x, $u = \frac{F \times \overline{b^2 - x^2}}{2a}$: if therefore l is made = 193 inches, being the ſpace which bodies falling freely from reſt by the force of gravity near the earth's ſurface deſcribe in one ſecond of time, the velocity of the circumference, when the extremity A of the index C A has arrived at the point H, will be = $\sqrt{\frac{2lF}{a}} \times \sqrt{b^2 - x^2}$. Let t repreſent the time in which the circumference deſcribes the arc B H; then will $\dot{t} = \sqrt{\frac{a}{2lF}} \times \frac{-\dot{x}}{\sqrt{b^2 - x^2}}$; and $t = \sqrt{\frac{a}{2lF}} \times$ a circular arc, of which the coſine $= \frac{x}{b}$ to radius = 1, which is the time of deſcribing the arc B H expreſſed in parts of a ſecond; when $x = o$, that is, when the circumference has deſcribed the entire ſemi-arc B O, the circular arc of which the coſine $= \frac{x}{b}$ is a quadrant of a circle to radius = 1. Let $p = 3.14159$, &c. the time t of deſcribing the ſemi-arc $BO = \sqrt{\frac{a}{2lF}} \times \frac{p}{2} = \sqrt{\frac{p^2 a}{8lF}}$.

In this expreſſion for the time of a ſemi-vibration, the letter a denotes the length of the arc O D (*fig.* 3.); if this arc ſhould be expreſſed by a number of degrees $c°$, a will then $= \frac{prc°}{180°}$; and this quantity being ſubſtituted for *a*, the time of a ſemi-vibration will be $t = \sqrt{\frac{p^2 r c^\circ}{8 l F \times 180^\circ}}$; if inſtead of F, its value $\frac{P r^2}{W g^2}$ is ſubſtituted in the equation $t = \sqrt{\frac{p^2 r c}{8 l F \times 180^\circ}}$, the time of a ſemi-vibration will be $t = \sqrt{\frac{W p^2 g^2 c}{8 P r l \times 180^\circ}}$.

Let the given arc c° be $= 90$; in this caſe $t = \sqrt{\frac{W p^2 g^2}{16 P r l}}$. Theſe are expreſſions for the time of a ſemi-vibration, whatever may be the figure of the balance, the other conditions remaining the ſame as they have been above ſtated. If the balance ſhould be a cylindrical plate, it is known that the diſtance of the centre of gyration from the axis is to the radius as 1 to $\sqrt{2}$; wherefore in this caſe $g^2 = \frac{r^2}{2}$; and the time of a ſemi-vibration, or $t = \sqrt{\frac{W p^2 r}{32 P l}}$."

Agreeably to this expreſſion, Mr. Atwood wiſhed to try the practical reſults of a chronometer made by Kendal, to prove how far his theory agrees with practice, and aſſuming the centre of gyration to be the ſame as if the balance were a cylindrical plate, he obtained from Mr. Earnſhaw the following data, *viz.*

W, the weight of the balance and vibrating parts = 42 grains.

P, the force at the circumference of the balance, which counterpoiſes the force of the ſpring when wound to the diſtance of 90° = 24 grains.

r, the radius of the balance = 1.125 inches.

l, the ſpace deſcribed in one ſecond of time by bodies which deſcend freely from reſt by the acceleration of gravity = 193 inches.

p, the circumference of a circle to radius 1 = 3.14159, &c.

The balance, when adjuſted to mean time, made juſt five vibrations in a ſecond; the actual time of a ſemi-vibration is therefore 0.1000.

Then *t*, the time of a ſemi-vibration by the theory, will be $= \sqrt{\frac{42 \times 3.14159^2 \times 1.125}{32 \times 24 \times 193}} = 0.0994$ parts of a ſecond; hence $0.1000 - 0.0994 = 0.0006$ is the difference between the actual time and the time by calculation from the theory; and the near coincidence of the two reſults proves that the ſuppoſition of the centre of gyration being nearly as in a cylindrical plate, is near the truth.

"It is obſervable," ſays our author, "that the ſemi-arc of vibration B O = *b*, does not enter into theſe expreſſions for the time of a ſemi-vibration; if, therefore, inſtead of the ſemi-arc B O, an arc of any other length L O, terminating in the point of quieſcence, (*fig.* 3.) ſhould be ſubſtituted in the preceding inveſtigation, the time of deſcribing L O would be ſtill $= \sqrt{\frac{a p^2}{8 l F}}$, or, $\sqrt{\frac{p^2 r c^\circ}{8 l F \times 180^\circ}}$, equal to the time of deſcribing the other ſemi-arc B O; conſequently, whether the balance vibrates in the largeſt or ſmalleſt arcs, the times of vibration will be the ſame. From the preceding inveſtigations it appears, continues our author, that when the force by which the circumference of the balance is accelerated at the given angular diſtance c° from the quieſcent poſition is = F, the time of a ſemi-vibration $t = \sqrt{\frac{p^2 r c^\circ}{8 l F \times 180^\circ}}$; and converſely, when the time of a ſemi-vibration is = *t*, the force which accelerates the circumference at the given angular diſtance c° from the quieſcent poſition, that is, $F = \sqrt{\frac{p^2 r c^\circ}{8 l t^2 \times 180^\circ}}$.

"Since time-keepers are uſually adjuſted to mean time when the balance makes five vibrations in a ſecond, the time of a ſemi-vibration will, in this caſe, be $= \frac{1}{10}$th part of a ſecond; the ſubſtitution of $\frac{1}{10}$th for *t* being made in the preceding equation, the force which accelerates the circumference of the balance, when at any given angular diſtance c° from the quieſcent poſition, will be determined for all time-keepers adjuſted to mean time, in which the balances make five vibrations in a ſecond. Suppoſe the given angle $c^\circ = 90^\circ$, then making $c^\circ = 90^\circ$, $p = 3.14159$, &c. $l = 193$, $t = \frac{1}{10}$, the accelerative force at the angular diſtance from quieſcence 90° or $F = \frac{p^2 r \, 90^\circ}{8 l t^2 \times 180^\circ} = r \times 1.00408926$. We have therefore arrived at the following concluſion; if the radius of the balance is equal to one inch, and the time-keeper is adjuſted to mean time when the balance makes juſt five vibrations in a ſecond, the force which accelerates the circumference of the balance at the diſtance of 90° from the quieſcent poſition is = 1.00408926, the accelerative force of gravity being = 1. And if the radius of the balance is greater or leſs than one inch, the force by which the circumference is accelerated at the diſtance of 90° from quieſcence will be greater or leſs than 1.00408926 in proportion to the radii.

"According to the principles aſſumed in the preceding ſolution, the ſpring's elaſtic force is ſuppoſed to vary in the proportion of the angular diſtances from the quieſcent poſition, and on this condition the vibrations are ſhewn to be iſochronous, whether they are performed in longer or ſhorter arcs; but if the ſpring's elaſtic force at different diſtances from quieſcence ſhould not be preciſely in the ratio here aſſumed, the longer and ſhorter arcs may be deſcribed in times differing in any proportions of inequality. If, for inſtance, the ſpring's force, inſtead of varying in the ratio of the aforeſaid diſtances, ſhould vary in the $\frac{999}{1000}$dth power or $\frac{1001}{1000}$dth power of the diſtances, it does not appear from the preceding ſolution what alteration in the daily rate would be cauſed by this change in the law of the force's variation, when the ſemi-arc of vibration is increaſed or diminiſhed by a given arc. To aſcertain this point fully, other reſearches will be neceſſary, by which it may be known, what alteration of the daily rate of a time-keeper is occaſioned by a given increaſe or diminution of the arc of vibration, when the ſpring's elaſtic force varies in a ratio of the diſtances from the quieſcent poſition, the general index or exponent of which is any number or fraction *n*.

"The force which accelerates the balance being aſſumed in that power of the diſtances, the exponent of which is *n*, let B O = *b*, (*fig.* 5.) be the ſemi-arc of vibration when the time-keeper is adjuſted to mean time; let D O = *a*; the accelerating force on the circumference at the diſtance from quieſcence O D = F; ſuppoſe the circumference to have deſcribed the arc B H from the extremity of the arc B; and let H O = *x*: then the force by which the circumference is accelerated when at the angular diſtance from the quieſcent poſition O H $= \frac{F x^n}{a^n}$; let *u* be the ſpace through which a body falls freely from reſt by the acceleration of gravity, to acquire the velocity of the circumference when it has deſcribed the arc B H: the principles of acceleration gave this equation $u = \frac{-F x^n \dot{x}}{a^n}$: taking the fluents while x decreaſes from b to x, $u = \frac{Fl^{n+1} - Fx^{n+1}}{\overline{n+1} \times a^n}$, and l being 193 inches, the velocity acquired by the circumference, after deſcribing B H, will be $= \sqrt{\frac{4lF}{\overline{n+1} \times a^n}} \times \sqrt{b^{n+1} - x^{n+1}}$; let T be the time of deſcribing the arc B H; wherefore $\dot{T} = \sqrt{\frac{\overline{n+1} \times a^n}{4lF}} \times \frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$. The time of deſcribing the arc B H will be the fluent of this fluxion, while x decreaſes from b to x, and the time of deſcribing the ſemi-arc B O will be the entire fluent of $\sqrt{\frac{\overline{n+1} \times a^n}{4lF}} \times \frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$, while x decreaſes from b to o. Now let the balance commence its vibration from any other point I, (*fig.* 5.) and let I O $= c$; ſuppoſe the circumference to have deſcribed the arc I K, and make O K $= y$; let t be the time of deſcribing the arc I K; then by proceeding in the ſame manner as in the former caſe, it is found that $\dot{t} = \sqrt{\frac{\overline{n+1} \times a^n}{4lF}} \times \frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$; and the time of deſcribing the ſemi arc I O will be the entire fluent of this fluxion, while y decreaſes from c to o. Although the fluents of the fluxions $\frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$, and $\frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$, cannot be expreſſed in general terms, yet the exact proportion of the ſaid fluents may be aſſigned, which will be the proportion of the times in which the balance vibrates in the two ſemi-arcs B O, I O; the multiplying quantity $\frac{\sqrt{\overline{n+1} \times a^n}}{4lF}$ being common to both fluxions; and ſince the entire fluent of $\frac{-\dot{x}}{\sqrt{b^{n+1} - x^{n+1}}}$ is to the entire fluent of $\frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$ as $b^{\frac{1-n}{2}}$ is to $c^{\frac{1-n}{2}}$, it follows that the time of a ſemi-vibration in the arc B O is to the time of a ſemi-vibration in the arc I O as $b^{\frac{1-n}{2}}$ to $c^{\frac{1-n}{2}}$, or as 1 to $\left.\frac{IO}{BO}\right|^{\frac{1-n}{2}}$.

Suppoſe a watch to be adjuſted to mean time when the ſemi-arc of the balance's vibration is $=$ B O, (*fig.* 5.) and let this ſemi-arc be afterwards diminiſhed to I O; the time ſhewn by the watch in any given portion of mean time t, when the ſemi-arc of vibration is I O, will be $= t \times \left.\frac{BO}{IO}\right|^{\frac{1-n}{2}}$; and if t is put $= 24^h$, the alteration of the daily rate, in conſequence of the diminution of the ſemi-arc of vibration from B O to I O, will be $24^h \times \left.\frac{BO}{IO}\right|^{\frac{1-n}{2}} - 1$. To apply this propoſition, let a caſe be aſſumed; ſuppoſe a watch to be regulated to mean time, when the ſemi-arc of vibration is 135°, and let this ſemi-arc be diminiſhed 8°, ſo as to become 127°; let the ratio of the ſpring's elaſtic force deviate from that of the diſtances from the quieſcent poſition by a ſmall difference of $\frac{1}{1000}$dth power of the diſtances, inſtead of in the entire ratio of the ſaid diſtances from the quieſcent poſition. The alteration in the daily rate of the watch will be obtained from the preceding theorem, by making the following ſubſtitutions; B O $= 135°$, I O $= 127°$, $n = \frac{999}{1000}$, the alteration of the daily rate $= 24^h \times \left.\frac{135}{127}\right|^{\frac{1}{2000}} - 1 = +\, 2''.62$."

From this theory of the balance and balance ſpring it is evident, that when there is a very minute alteration in the law of the force's variation, amounting to no more than $\frac{1}{1000}$dth part of the entire ratio of the diſtances, an acceleration is cauſed in the daily rate of more than 2½″, when the diminution of the ſemi-arc is only 8°, and as this alteration in the force is leſs, probably, than can be detected by actual meaſurement of the force by mechanical means, it is very probable that a much greater acceleration or retardation of the rate, than in the example before us, may occur from the ſame cauſe, which can only be corrected by a correſponding alteration either in the length or ſtrength of the balance ſpring, or both, as the caſe may require, and the beſt way of detecting the law of force by which the ſpring acts at different diſtances from the quieſcent poſition, is by increaſing or diminiſhing the maintaining power, ſo as to render the arc of vibration unequal in ſucceſſive trials for a limited time. The neceſſary concluſion, from ſuch trials with different maintaining powers, will be, that when an acceleration of the daily rate accompanies a diminution of the arc of vibration, the elaſtic force of the ſpring uſed varies in a leſs ratio than that of the diſtances from the quieſcent poſition; but on the contrary, when a retardation takes place under the ſame circumſtances, the ſaid elaſtic force varies in a higher ratio than that of the diſtances from the point of quieſcence. We here ſuppoſe the ſame eſcapement to be uſed in all the trials, and that the impulſe given to the balance is no more than ſufficient to overcome the inertia of the balance and the reſiſtance it meets with from friction and the denſity of the air; but as there is generally an overplus of power communicated to the balance to guard againſt ſtopping by the acceſſion of dirt or thickening of the oil, this ſuperfluous power has ſuch an influence on the balance and its ſpring when in motion, as to produce a compound law of varying forces, ſomewhat different from the ſimple law derived ſolely from the elaſticity of the ſpring, and the more this compound law varies from the ſimple law derived from the ſpring's elaſticity, the greater will be the diſcrepancy between the theory and performance of a watch balance. The buſineſs of a good eſcapement of a watch or balance clock is to keep the balance in continual motion with as little interference as poſſible with the ſimple law of its natural varying forces, which it has been ſhewn are in proportion to the diſtances from the point of quieſcence.

After theſe remarks on the laws by which a pendulum and a balance together with its ſpring become the regulators of an horological machine, the reader will be able to form an opinion, founded on ſcientific principles, on the merits or demerits of the different eſcapements that are ſucceſſively deſcribed, not only in this article, but in the articles CHRONOMETER and CLOCK, which have been already publiſhed.

Henry Sully, who was an ingenious clock and watch maker about the beginning of the 18th century, wrote a hiſtory of the eſcapements of his time down to the year 1727, which Julien le Roy added to Sully's "Regle Artificielle du Temps," in the ſecond edition, publiſhed at Paris, 1737, from which Berthoud has extracted his account of ſeveral eſcapements in his "Hiſtoire de la Meſure du Temps," and which we mean to avail ourſelves of in a certain degree in our ſubjoined deſcriptions.

The different eſcapements of clocks and watches may be divided into four claſſes; *viz;*

1. Thoſe with a *recoil*, or which produce a backward motion of the eſcapement wheel and ſecond's hand in ſome parts of the vibration; (echappement a recul.)

2dly. Thoſe that have the *dead-beat*, or that allow the eſcapement wheel and hand to reſt while the whole vibration is made; (echappement a repos.)

3dly. *Detached*, or *free* eſcapements, which act on the balance or pendulum an almoſt inſenſible time, and ſuffer the vibration to be performed almoſt without connection with the pallets; (echappement a vibrations libres.)

4thly. *Detached*, or *free* eſcapements with a *remontoir*, or auxiliary ſpring frequently wound up by the maintaining power, to equaliſe the arcs of vibration; (echappement a vibrations libres et a remontoir d'égalité d'arcs.)

The moſt ancient eſcapement in uſe at this time, and probably the firſt that was ever contrived, is the *crown-wheel eſcapement* at preſent employed in our table-clocks and common watches; we know not who was the original inventor, but find mention made of it by Leonard de Vinci, who died in the year 1513; and Venturi thinks that the horological machines of Wallingford and Dondi, early in the fourteenth century, had the ſame, as we have ſeen, under our article Clock, that Henry de Wyck's clock had in the year 1364. The idea of converting a rotatory into a vibratory motion, and the means adapted to effect this purpoſe mechanically are equally ingenious; as an effort of genius this thought is much to be admired. We have already given a general deſcription of the connection that the eſcapement-wheel has with a train of wheel-work on one ſide of it, and with the balance on the other, under our article juſt referred to, but as the balance had no rim, and was without the *regulating*, or, as it is ſometimes called, the *pendulum ſpring*, we think it right to give a ſeparate drawing and deſcription of this eſcapement, as made at preſent, together with ſome remarks on its properties.

1. *Crown-wheel eſcapement.*—In *Plate* XXXI. of *Horology*, *fig.* 6. repreſents the crown-wheel and balance in connection, which may be in either a horizontal or vertical poſition, and is in fact ſometimes in one poſition and ſometimes in the other in a common watch agreeably to the different poſitions of the body of the wearer; and it is eaſy to conceive that a ſhort pendulum might be ſubſtituted for the balance when the crown-wheel moves horizontally in a fixed poſition, and the axis of the balance is placed horizontally, which is the caſe in moſt of the portable clocks. The name of crown-wheel is taken, no doubt, from the reſemblance it has to an old faſhioned *royal diadem*; but when applied to a watch it is frequently called ſimply the *balance-wheel*, from its connection with the *balance*: this wheel and the balance, including the pallets and regulating ſpring, may be conſidered as conſtituting the *eſcapement*, the action of all which may be underſtood from the following ſhort account.

Suppoſe the pinion *a*, on the arbor *a b* of the balance-wheel or crown wheel *c d*, to be actuated by the main-ſpring, or weight which forms the maintaining power, by means of the rain, in the direction *c f d e*, while the pallets *e* and *f*, attached to the axis of the balance *g h*, and ſtanding at right ngles to each other, or very nearly ſo, are long enough to all in the way of the ends of the ſloped teeth of the wheel, hen turned round an angle of 45°, ſo as to point in oppo-ite directions, as in the figure; then a tooth of the wheel elow, for inſtance, meets with the pallet *f*, ſuppoſed to e at reſt, and drives it before it a certain ſpace, till the end of the tooth *eſcapes*; in the mean time the balance attached to the axis of the pallets moves in the direction *h k g*, and winds up the ſmall ſpiral ſpring *i*, one end of which is faſt to the axis and the other to a ſtud on the plate of the frame, in this operation the ſpring oppoſes the momentum given to the balance by this puſh of the pallet *f*, and prevents the balance from going quite round before the pallet *e* meets with another tooth at the oppoſite end of the wheel's diameter; here this pallet receives a puſh which carries the balance back again, having as yet but ſmall momentum, in the direction *h l g*, and aids the ſpring, which now unbends itſelf till it comes to its quieſcent poſition, but beyond that point is unwound, partly by the puſh from the maintaining power on the pallet *e*, and partly by the acquired momentum of the moving balance, particularly when this pallet has eſcaped; at length pallet *f* again meets with the ſucceeding tooth, and is carried *backward* by it, in the direction the balance is now moving in, till the maintaining power and force of the unwound ſpring together overcome the momentum of the balance; during which time the *recoil* of the ſecond's hand is apparent, when put on the pivot of the arbor *a b*; at length the wheel brings the pallet *f* back again till it eſcapes, and the ſame proceſs takes place with pallet *e* that has been deſcribed with reſpect to pallet *f*, and thus two contrary excurſions, or oſcillations of the balance, take place before one tooth has completely eſcaped, which is the reaſon why there muſt be always an odd number of teeth in this wheel, that a ſpace at one ſide of the wheel may always be oppoſite to a tooth at the other, in order that one pallet may be out of action while the other is in action. The ſame account will apply to the vibrations of a ſhort pendulum ſubſtituted for the balance, when this eſcapement is uſed. This eſcapement, which is of the firſt claſs, is evidently calculated to derange the natural law of the ſpring's varying force, which, we have ſeen, is in theory in proportion to the diſtances from the quieſcent poſition; for as the action of the maintaining power continues to preſs on the pallets, either with or againſt the balance's motion, during a large portion of each vibration, this extraneous force acting along with the elaſtic force of the ſpring makes a new law compounded of the two forces, which may or may not be a regular law, as modified by circumſtances, that are to be taken into conſideration; for inſtance, the relative forces of the maintaining power and of the regulating ſpring, the uniformity of each force ſeparately conſidered, the ratio between the radius of the pallet-wheel and length of the pallets, the weight and diameter of the balance, the angle of action in the eſcapement relatively to the whole arc of vibration, the adjuſtment of the length and ſtrength of the ſpring for iſochroniſm, and of its quieſcent place to the poſition of the pallets, together with the friction and inertia of the acting parts, as well as reſiſtance of the air to the moving balance muſt all enter into the account, which complex data render all calculations founded in theory very inadequate to their purpoſe of determining the practical reſults independently of experimental trials, which are neceſſarily adopted by the workmen in finiſhing the adjuſtments. The bad effect of an almoſt conſtant force on the balance, as derived from the maintaining power, is evident by the application of the key to the fuſee-arbor of a watch, and by urging it in a direction contrary to that of winding up, for the additional force thus given to the maintaining power, will very ſenſibly accelerate the beats of the watch, and leſſen the arc of vibration; hence any inequality occaſioned in the maintaining power, by the acceſſion of dirt, or by want of perfect compenſation in the fuſee of the varying force of the main-ſpring, &c. will alter the daily rate very materially, though the mechanical adjuſtments at the balance may, in the firſt inſtance, have produced jointly a law of varying forces in the regulating mechaniſm that ſhall approximate near enough to the iſochronous law of the balance ſpring, while the arcs of vibration remain unaltered. It is of the utmoſt importance, therefore, when a crown-wheel eſcapement is uſed in any watch, that, whenever a new main-ſpring is put in, the fuſee ſhould alſo be altered, ſo as to become as perfect a compenſator as poſſible for that *identical ſpring*, which, we believe, is ſeldom, if ever, attended to in practice. This eſcapement uſually has a pin in the rim of the balance that may catch a notch on each ſide of the cock beyond the extremities of the longeſt vibrations, called the *banking*, to prevent the derangement of the balance and of its regulating ſpring by any ſhake or accident.

2. *Eſcapement a pirouette by Huygens.*—About the year 1675, when Huygens was contriving the beſt conſtruction he could deviſe of a marine time-piece, he naturally dwelt upon the portability of the balance, as affording the likelieſt plan of accompliſhing his purpoſe, but he was aware that the balance vibrating in ſhort arcs was not comparable in point of ſteadineſs to a pendulum, as a regulating principle, ſeeing it is too much under the controul of the maintaining power, when uſed with the crown-wheel eſcapement, the only one at that time known. The balance under ſuch ſtrong influence, and that a variable influence, had the property of putting itſelf into motion when in a ſtate of reſt: Huygens, therefore, made ſuch additions to the balance and eſcapement then in uſe, as produced much longer vibrations than had been before witneſſed, and introduced an additional wheel and pinion between the pallet-wheel and the balance to effect this object; thus, in *fig.* 7. of our laſt plate, is a ſide view of a ſmall frame containing the mechaniſm of Huygens' eſcapement, conſiſting of two wheels, one pinion, a pair of pallets, and a balance with the ſpiral ſpring, together with the requiſite cocks to bear the pivots of the arbors; *a b* is the crown-wheel or pallet-wheel of the uſual ſhape and number of teeth, placed in a vertical poſition, like the contrate wheel of a common watch or table clock; *c d* is a contrate wheel placed horizontally, like the pallet-wheel of a common watch, having two pallets *e*, *f*, as uſual on its arbor, at right angles to each other, and acting exactly as we have explained above; the contrate wheel *c d* drives a pinion *g* on the axis of the balance *h*, under which, as uſual, is the ſpiral ſpring *i*; the action of this eſcapement differs from that of its predeceſſor only, inaſmuch as the contrate wheel impels the pinion ſeveral times round at each impulſe of one of the pallets, thereby occaſioning ſeveral revolutions of the balance itſelf at each oſcillation; and Sully ſays, that when the ſpring is not uſed he has ſeen the oſcillations performed in the ſpace of two ſeconds, and with a ſpring in one, in imitation of a ſeconds' pendulum clock, to which this eſcapement is not applicable. The influence, however, of the maintaining power muſt have been exerted on the balance in this conſtruction alſo, during at leaſt one of its revolutions, and the extraneous force interfering with the law of the ſpring's varying forces would produce a compound ſcale of forces, in which, as in the former inſtance, one would be nearly conſtant while it acted, and the other varying; beſides, the friction in the teeth of the wheel and pinion, however well executed of the reſpective ſizes and ſhapes, would produce checks that would be unfavourable to the ſteady oſcillations of the balance, we therefore are not ſurpriſed to find that this eſcapement, which was of the firſt claſs, was ſoon diſcontinued.

3. *Eſcapement with two balances by Dr. Hooke, and by Du Tertre.*—Dr. Hooke, ſays Sully, produced a balance in the year 1675, which he had invented in 1658, with two balances engaging each other by means of teeth cut in their edges, and one of them having a ſpiral ſpring on its verge or axis; but Berthoud attributes the invention of this eſcapement with two balances, without the ſpring, to a German artiſt on the authority of Thiout (Traité d'Horlogerie de Thiout) where there is a drawing of the eſcapement in queſtion; J. B. Du Tertre afterwards made ſome additions, which we have given in *fig.* 8. of *Plate* XXXI., and of which the following is a deſcription, *viz.*; A and B are two balances acting together, like wheels with equal numbers of teeth, and having on one of the croſſes of each a pallet, at *a* and *b* reſpectively; at equal diſtances from the axes of theſe balances is the arbor of the laſt wheel of the train, bearing two ſtars with each five radii, one numbered 1, 2, 3, &c. which is ſmaller than the other, lying the lower in poſition, and the other marked *d e f*, &c. with radii long enough to reach almoſt to the centres of motion of the balances, which they can paſs only when the ſemi-circular parts that are cut away are preſented to them; but at other times they reſt againſt the central ſemi-circular pieces that remain uncut: the radii of the ſmall ſtar reach far enough to fall on the pallets *a* and *b* ſucceſſively, which they impel alternately, and give motion to both balances at the ſame time; but the eſcape takes place by means of the radii of the large ſtar, that reſt ſucceſſively againſt the ſemi-circular portions of metal not cut away, above the centres of the balances reſpectively. The three axes ſtand in the angles of an iſoſceles triangle, and have their upper pivots ſupported by three ſeparate cocks, placed over the upper plate of the frame, the lower pivots of the balances reſting on the upper plate, but the arbor of the two ſtars paſſing acroſs the frame to take the laſt wheel. The action is thus; radius 1 of the ſmall ſtar has parted with the pallet *a* of balance B, and the long radius *d* is eſcaping; preſently radius 4 will fall on the pallet *b* of balance A, and impel it in a direction from 4 to 5, the balance B at the ſame time moving in a contrary direction; this impulſe will continue till the radius 4 falls from the pallet, ſoon after which the long radius *g* will fall on the ſemicircular central piece of balance A, and ſtop the further motion of the two ſtars, which move together on the ſame arbor, and the balances will go on in their vibrations till the ſpring under balance B brings them back again, ſo as to preſent the cut half of the central piece of balance A to the point *g* of the long radius, which, being impelled by the train, now eſcapes; the ſtars go on till radius 4 of the ſmal ſtar meets with the pallet *a* of balance B, the motion o which it now oppoſes, and is itſelf brought back, ſo as to make a recoil of the hands till it has ſtopped the motion o the balances, which now begin each another oſcillation: thi radius 4 eſcapes the pallet *a*, and the long radius *g* falls on th ſemi-circular piece, at the centre of balance B, as it did before on that of balance A; the oſcillation continues forwar again till the ſpring brings it back, when another followin radius of the ſmall ſtar falls again on the pallet *b* of balanc A, as before, and drives it; ſoon after which a ſucceeding lon radius falls on its ſemi-circular central piece, and reſts till a the return of the oſcillation it can eſcape; thus an alternatio of oſcillations is produced by the ſhort radii acting alternat ly on the two balances, while the long radii ſuſpend the in pulſes by reſting on the ſemi-circular parts of the centres the balances, during the latter portion of each excurſio This eſcapement was evidently of the firſt claſs, like its pr deceſſors, and though it avoided the jerk uſually given one balance by the ſtroke of the pallet, yet was ſubject to th friction ariſing from the action of the teeth, like the prece

ing one; it had, however, a capability of making the angle of action and angle of the balance's motion before the eſcape in any ratio to each other, by altering the lengths or number of the radii reſpectively, as well as the diſtance of the pallets from the centres of motion; it had alſo the good property of preventing an increaſe in the maintaining power from affecting the balances in the ſame proportion, by the long lever preſſing againſt the ſemi-circular central part of the balances alternately, during the latter part of the excurſion of the balances, ſo as to check any acceſſion of momentum occaſioned by an acceſſion of maintaining power: the law of this preſſure, however, might be modified by changing the figure of the ſemi-circular piece into a ſpiral ſhape, ſo that the preſſure might bear a proportion to the angular diſtances of the balances from the ſpring's quieſcent poſition. The friction in both caſes, it muſt be admitted, would be detrimental to the performance. The banking, we preſume, in this eſcapement, was the ſame as in an ordinary watch, as no remark is made thereon. The invention, it appears, muſt be attributed to three ſucceſſive artiſts; firſt the German, whoever he was, invented the eſcapement without the balance ſpring, and with the ſmall ſtar only, in which ſtate it would act under the controul of the main-ſpring, without the regulating ſpring: ſecondly, the regulating ſpring was added by Dr. Hooke, and, thirdly, the large ſtar was introduced by Jean Baptiſte Du Tertre, about the year 1724, which addition completed the eſcapement as given in our drawing, which in its preſent ſtate will not act without a regulating ſpring. Of courſe this laſt addition followed Tompion's and De Baufre's eſcapements hereafter deſcribed, from which probably the idea of the large ſtar preſſing on the circular part of the axis of motion was derived. Each addition was evidently an improvement on the original German eſcapement as deſcribed by Thiout; but the number of pivots in motion, and the increaſed friction occaſioned by the preſſure of the ſemi-cylindrical pieces at the centres of the balances, were obſtacles too powerful to be overcome in this conſtruction.

4. *Firſt dead beat eſcapement by Tompion.*—The ingenious Tompion of London was probably the firſt watch-maker who contrived an eſcapement without recoil, or eſcapement of the ſecond claſs, called a *dead-beat* eſcapement from the circumſtance of the ſecond's hand remaining motionleſs, or, as it were, dead, during the motion of the balance after the eſcape. Sully ſays that he ſucceeded in effecting this about the year 1695. In this eſcapement, of which *fig.* 7. of *Plate* XXXV. is a plan, the balance verge carried a cylindrical piece of metal *a b c*, terminating with a pallet *c*, with a notch cut between *a* and *c* to allow the eſcape of each ſucceſſive tooth of the balance wheel. This wheel had its plane parallel to the planes of the plates of the frame, and its teeth bent at the end, and ſo diſtant, that the cylindrical piece and pallet could revolve between any two of them. When the cylindrical part of the pallet preſented its notch to a contiguous tooth of the eſcapement wheel, it received a puſh therefrom, which put the balance in motion, and the next ſucceeding tooth falling on the circular or cylindrical portion of the pallet, now in motion in the direction *c b a*, reſted againſt it without recoil till the balance ſpring had brought the notch back again, when it eſcaped in its turn by giving its puſh, and a third tooth fell on the cylindrical part of the pallet, and in like manner remained motionleſs till the notch came back again and allowed the eſcape: thus one eſcape took place at every alternate vibration, and the contrivance was admirably calculated to prevent the bad effect on the balance of any change in the impulſes derived from the main-ſpring; but the friction on the back of the pallets when large, and at the balance pivots occaſioned by the preſſure of the reſting teeth, conſtituted the ſame objection in practice as applied to Du Tertre's modification of the eſcapement with two balances. This eſcapement, however, was the archetype of all the ſucceeding dead-beat eſcapements, and therefore is deſerving of the notice we have given it.

5. *Cylinder eſcapement in diamond by De Baufre.*—A native of Geneva of the name of Facio had applied rubies to the pivot holes of a watch about the year 1700, and went into partnerſhip with De Baufre, a French watch-maker, eſtabliſhed in London; the latter artiſt finding the advantage of applying the poliſhed ſurfaces of the precious ſtones for diminiſhing friction at the parts of action, contrived a new eſcapement about 1704, of which the pallets were of diamond. Sully ſays that a watch of De Baufre, with the diamond pallets, was put into his hands by ſir Iſaac Newton, who had found its accuracy of performance admirable. The following account will be intelligible, we preſume, to any artiſt who underſtands the mechaniſm of a watch. The balance had two pallets on its verge conſiſting of a ſemi-cylindrical diamond, and the eſcapement wheels, of which there were two, were vertical, with their common arbor at right angles to the verge of the balance; *i. e.* with their planes parallel to the verge: theſe wheels, which were ſimilar, were placed one oppoſite the other on contrary ſides of the verge in ſuch way, that a tooth of one fell in the middle of the ſpace of the other, and *vice verſâ*; the pallets were $\frac{1}{24}$th of an inch thick, and two and a half twelfths in diameter, and the diſtance between the ends of the teeth of the double eſcapement wheel about $\frac{1}{12}$th of an inch, or twice as much as the thickneſs of the pallets; the pallets had their planes parallel to the plane of the balance, and had their ſemi-circle ſloped in an angle of about 45° at the ends for the pallets to ſlide over, after preſſing on their planes alternately during the reſpective oſcillations. We will endeavour to explain the action, as we comprehend it to have been by a verbal deſcription. Let the leading pallet be called *a*, and the following pallet *b*; and let the balance be ſuppoſed in motion with a tooth of the eſcapement wheel reſting on the plane of the diamond; when the ſloped end of pallet *a* arrives at the ſaid tooth, the tooth falls off, accelerating the balance by its ſliding motion, and goes on till an oppoſite tooth of the other wheel falls on the plane of the diamond in motion; this tooth reſts without recoil, as did the former one, till the ſloped end of the pallet *b* comes to it, when it falls off in its turn, and gives motion to the balance, which has thus its ſpring wound up by the momentum of the balance ſufficiently far to bring the balance back again after every impulſe; and thus an alternation of vibrations is continually maintained while the force of the mainſpring laſts. This eſcapement is alſo of the ſecond claſs, or of the dead-beat kind, but is ſubject to the conſtant friction of its immediate predeceſſors, though this friction is greatly diminiſhed by the ſubſtitution of the diamond for metallic pallets, and by the buſhing of the pivot holes with rubies; it poſſeſſed all the good properties of Tompion's eſcapement juſt deſcribed. (See Machines and Inventions approuveés, &c. vol. vii. p. 137.) Larcum Kendal uſed two crown wheels in a ſimilar manner, which W. Howell improved by adding a forked detent to make the eſcapement detached, which was rewarded by the Adelphi Society, in 1792. See their Tranſactions, vol. x. p. 216.

6. *Sully's modification of De Baufre's eſcapement.*—The praiſe which ſir Iſaac Newton beſtowed on De Baufre's new watch induced H. Sully to beſtow much attention on it, and in the year 1721 he adopted an alteration in it, which made only one wheel neceſſary for the eſcape at both oſcillations;

lations; but Berthoud has expreſſed an opinion that his alteration conſtituted no real improvement, but made the adjuſtment of the pallets more difficult. Sully having applied his modification of the eſcapement in queſtion both to a pendulum clock and a marine time-piece, preſented two memoirs on its conſtruction to the Royal Academy of Sciences in the years 1723 and 1724; which are alſo printed in his deſcription of marine time-pieces, publiſhed in 1726. *Fig.* 1. of *Plate* XXXII. of *Horology*, repreſents a ſide view of this eſcapement, where A is the eſcapement wheel, B the contrate wheel between it and the balance C, which has a pinion only on its verge, that is actuated by the contrate wheel; the pallets 1, 2, are two circular pieces of agate, placed at the diſtance from one another of one ſpace of the eſcapement wheel nearly; theſe pallets have each an inclined or ſloped end, like De Baufre's, the ſlopes alſo being at the contrary ends of each; the intention of this modification is not only to make one wheel A perform the whole buſineſs of the eſcapes, but to produce long vibrations of the balance, even beyond a complete circle. The action was thus; on giving motion to the balance C, ſuppoſe the tooth *b* to reſt on the plane of the pallet or agate 1, it ſoon meets with the end ſlope, and falls off till it meets with the pallet 2 below, on which it reſts, after having given a puſh to the pallet during the act of ſliding off; the balance goes on, till the ſpring, now wound up, brings it back, there being in the mean time no recoil, by reaſon of the arbor of the contrate wheel being alſo the axis of the pallets, and at right angles thereto; the tooth *b* now finds, after the return of the balance, the ſloped end of pallet 2, and eſcapes entirely; but at the ſame inſtant tooth *c*, which follows, falls on the plane of pallet 1, and is then in the ſame ſituation we at firſt found *b* in, therefore the ſame action is repeated with this, and every ſucceeding tooth, till the power of the main-ſpring is exhauſted. This modification of De Baufre's eſcapement is conſequently of the ſecond claſs alſo, and enables us to comprehend more clearly the action of the original one, which had its double eſcapement-wheel placed with reſpect to the balance verge, as the preſent one has its ſingle one, with reſpect to the arbor of the contrate wheel. The effect produced muſt have been nearly the ſame on the pallets, though the vibrations of the original balance muſt neceſſarily have been ſhorter than of the latter, but then it had not the friction in the wheel-work between the pallets and balances.

7. *Eſcapement with two cylindrical pallets.*—In the year 1727 Julien le Roy ſhewed Sully ſome watches juſt brought from England into France, which had each two cylindrical pallets with notches cut in them like Tompion's ſingle pallet, which kind of eſcapement ſeems to have differed from his, only in having an eſcape at every vibration, and in having the old crown-wheel as an eſcapement wheel; but as we have not been able to trace the inventor of this eſcapement, we muſt conſider it as a lineal deſcendant from Tompion's, and therefore as a variety of Engliſh extraction. Its utility has been, however, evinced by the circumſtance of Julien le Roy's having adopted it as a favourite, and uſed it in ſome of his productions: it had the property of converting the recoil of the crown-wheel into a dead-beat.

8. *Cylinder or horizontal eſcapement of Graham.*—We are not informed in what particular year Mr. Geo. Graham, the celebrated watch and clock-maker, invented the eſcapement with a cylinder, called alſo the horizontal eſcapement, from its wheel being in an horizontal poſition, but it appears that Julien le Roy introduced this conſtruction into France in the year 1728, when wonderful properties were attributed to it, but particularly the property of compenſating all the inequalities of the maintaining power, which at that time was the great deſideratum among watch-makers. The contrivance bears a great analogy to Tompion's eſcapement, and was probably originally derived from his, which, however, does not leſſen the merit of the contrivance, as it requires as much ingenuity to improve an exiſting inſtrument, frequently, as to invent a new one. *Fig.* 2. of *Plate* XXXII. is a perſpective view of Graham's horizontal eſcapement, in which A is the eſcapement-wheel, B the balance, and C the hollow cylinder fixed on the verge of the balance; each tooth of the wheel, which may have any convenient number of teeth, is formed of a triangular inclined plane or wedge, ſupported by a ſtem projecting perpendicularly from the plane of the wheel at its circumference; the length of the wedge of each tooth is juſt a diameter of the internal part of the cylinder, ſo that the cylinder may revolve round the wedge when the balance is in motion; in this ſituation the anterior point of the wedge juſt touches the cylinder's interior ſurface, but the poſterior point of the ſame is free, ſo as not to touch and ſtick faſt in the cylinder, but to give it a puſh on the edge when the contact ceaſes; the diſtance between the teeth is alſo great enough to allow the exterior portion of the cylinder to come between them, when the eſcape has taken place, and while the balance continues its oſcillation. The action is performed in the following manner; ſuppoſe the wedge to be juſt eſcaping from the hollow part of the cylinder, and to be giving its impulſe to the edge of the cylinder which it quits, the balance goes on and winds up the ſpring, as uſual, at the ſame time preſents its exterior face, or convex ſurface to the point of the ſucceeding tooth or wedge; this point falls on the ſaid convex ſurface and reſts there, without recoil, till the oſcillation is finiſhed, at the return of the balance, by means of the ſpring now wound up, the hollow or concave part of the cylinder comes to the point of this following wedge, and being rounded at this end, admits it eaſily into its concavity, at which inſtant the other edge of the cylinder receives a ſecond impulſe in a contrary direction; the balance now makes another oſcillation, and the point of the wedge reſts againſt the interior face of the cylinder, as it did before on the exterior, without recoil, and in both ſituations of reſt the wedge has no other effect on the balance than that of retarding it by its preſſure againſt the circular ſurface; the ſecond tooth is now in the ſame ſituation as we found the firſt, and preſently in its turn gives another puſh at leaving the cylinder altogether, and leaves the third wedge to perform the ſame office by firſt reſting on the back of the cylinder, then entering it, and laſtly giving its parting impulſe to the ſecond edge of the ſaid cylinder, as the two wedges that preceded had ſucceſſively done before. At one period this eſcapement was in high eſtimation in England, as well as on the continent, and even now the common watches that are conſtructed with this eſcapement will fetch greater prices than thoſe with the ordinary crown-wheel eſcapement, but the detached eſcapements of the beſt chronometers are now held in much higher eſtimation than either. We have ſeen that the hollow cylinder, though conſtituting but one pallet, in effect performs the office of two pallets, and permits but one tooth or wedge to eſcape entirely at two oſcillations, during one of which the point reſts at the outſide, and during the other at the inſide of the cylinder, while the two edges of the cylinder perform the part of ſeparate pallets on receiving ſeparate impulſes in contrary directions, it is, therefore, of importance in this, as indeed in all eſcapements with a regulating ſpring, that the quieſcent poſition be duly adjuſted to render both oſcillations preciſely ſimilar in extent and duration at each ſide, otherwiſe the performance will be a ſpecies of hobbling, and the compound law of motion,

derived from the ſpring's action and impulſes on the pallets conjointly, will be far from regular; conſequently not likely to be an iſochronal law. Berthoud has deſcribed a cylinder eſcapement with two balances connected by two pinions, but it did not prove ſucceſsful.

9. *French eſcapement a Virgule.*— The French eſcapement known by the appellation of *a virgule*, from the pallet's reſemblance of a *comma*, is repreſented by *fig.* 6 of *Plate* XXXV. A, B, C, are three teeth of the balance wheel, placed very obliquely compared to a true radial line, and carry each a pin at their extreme ends, ſtanding vertically like the ſupports of Graham's wedges for his cylindrical eſcapement; the pallet B A has its centre of motion at *c*, the centre of both the concave and convex portion, exactly over the verge of the balance; this centre is in the circumference of the circle that paſſes through the points or pins of the teeth; the pallet, which is of hardened and poliſhed ſteel, has its plane parallel to that of the wheel, and is ſupported between *f* and *e* by a crank piece put over the verge, which cannot be admitted as high as the pallet; this end *a o*, which connects the convex and concave portions, is a portion of an equi-angular ſpiral, and the part *b d* of the pallet is called the *horn*, probably from its reſemblance of the beak of a bird; the inferior face *b* A may be ſtraight like the dotted line, or curved, at the option of the maker, and the ſuperior part *f* A may be of any ſhape: the convex part *a e f* contains about 100°. The length of the pallet from *a* to *d* is ſuch, that when the pin at B preſſes againſt the curved part at *a*, the point *d* of the horn will juſt miſs the pin at A of the preceding tooth, and the height at which the pallet ſtands is ſuch as to make it paſs over the rim of the wheel, but not over the pins at the ends of the teeth. When the balance is at reſt, and has its ſpring in equilibrio, the point *d* of the horn is at the point *i*, about 30° from *d*; but the preſent poſition is that which the pallet has when the tooth A has juſt eſcaped from the point *d* of the horn. To explain the action, on a ſuppoſition that the tooth A has juſt eſcaped, the ſucceeding pin B has juſt fallen on the point *a*, joining the ſpiral and convex portions of the pallet, and the balance has juſt received its impulſe from tooth A as it paſſed from *b* to *d* along the inferior face of the horn; it, therefore, proceeds in its motion in the direction *d g h* of the dotted circle, while the point B ſlides on the convex ſide *e f*, and is detained without recoil; when the point *d* of the horn has arrived as far as *h*, more than 90° from A, the momentum of the balance is exhauſted, and the balance returns; the point *d* comes to about the point *i* before the pin of tooth B comes to *o*, and enters the concave part of the pallet, where it ſlides till the point arrives about *k*, where the momentum of the balance ſpring is again exhauſted; the balance returns again, and when the point *d* comes to *i*, the pin of tooth B eſcapes the concave part at *b*, and ſlides along the inferior face of the horn, at the ſame time giving it a puſh till it eſcapes entirely, and is in the ſituation of tooth A, where the proceſs began; in the ſame manner the following tooth C, and every ſucceeding tooth in its turn, will fall on the convex ſide of the pallet, return and enter the concave ſide, and then finally eſcape. We muſt obſerve, however, that the pallet oppoſes the motion of the balance as it paſſes along the ſmall ſpiral part from *a* to *o*, which may be ſo proportioned as to be a counterbalance to the impulſe previouſly given to the balance by the leading tooth, in caſe the friction on the back of the cylindrical part is not competent to retard the balance's impulſe ſufficiently. The effect produced by this eſcapement muſt be very ſimilar to that produced by Graham's cylindrical eſcapement, but has this advantage, that the inclined plane formed on every wedge of Graham's conſtruction is transferred to the pallet, and ſerves for all the pins to ſlide on in ſucceſſion, thereby removing the difficulty of forming all the wedges alike in ſize and ſhape. Beſides, the convex and concave ſides of the pallet may be reduced to any dimenſions, provided the acting tooth may not ſlide at once from the ſpiral to the horn, and allow the train to run down, which may be the caſe if the parts of action be ſmall, and there be much play in the pivot holes of the wheel and balance. The conſtruction is a compound of Tompion's and Graham's watch eſcapements, to both of which it has certain points of reſemblance. In 1752, Le Paute altered this eſcapement, by putting pins for teeth in both planes of the wheel, as he did in Amant's eſcapement *a cheville*, which addition gave it ſome advantages.

10. *Eſcapement with one pallet and one detent by Thiout.*— Thiout, a French clock-maker of conſiderable eminence, publiſhed a work in 1741, entitled "Traité de l'Horlogerie Mechanique et Practique, approuvé par l'Academie Royale des Sciences," 2 vols. 4to, in which he has deſcribed an eſcapement of a watch that has been miſtaken ſometimes for a real detached eſcapement, and conſidered as the firſt that has been made of ſuch a conſtruction, though the inventor himſelf did not conſider it as ſuch, as is evident from his own deſcription. This eſcapement is given in *fig.* 8. of *Plate* XXXII., and to uſe the author's own account, "it is an eſcapement of a watch in which half of the vibrations *ſeem* independent of the train of wheels, while they are performed. The detent B ſtops the eſcapement wheel, the balance bringing back the pallet A, the detent recedes, to leave the wheel free to ſtrike the pallet; and ſo on. This eſcapement could not perform without a ſpiral ſpring." It hence appears, that the pallet A is on the verge of the balance, but that the detent B is on a ſeparate arbor, while they are connected by the tail of the pallet entering the ſlit in the remote end of the detent, ſo that the balance is never diſengaged from the detent, and therefore cannot be conſidered as of the detached claſs. When the balance moves in a direction from A to B the pallet gets out of the teeth, but the detent falls in, and *vice verſâ*. The curves of the claw of the detent appear to have been drawn from the centre of its motion, and therefore we are diſpoſed to think that there would be no recoil in the eſcapement wheel.

11. *The anchor eſcapement by Clément, or Dr. Hooke.*—While theſe improvements were going on in watch eſcapements, an equal attention was paid to the contrivance of new clock-eſcapements. Huygens had placed the pallets of the crown-wheel eſcapement at an angle of about 60° inſtead of 90°, as they were made for a watch, in order that they might be accommodated to the ſhort vibrations of a pendulum, or rather, perhaps, to the vibrations of ſome length performed in a cycloidal curve, by means of his cycloidal cheeks near the point of ſuſpenſion; but ſtill the arc of action on the pallets was too long to allow practice and theory to coincide, as to the performance of long and ſhort arcs of vibration in the ſame time. The preference that ſeemed due to ſhort arcs, when circular, ſuggeſted the propriety of contriving an eſcapement that would admit of very ſhort arcs of vibration. This was firſt effected about the year 1680 according to Smith's account, by Clement, who was a clock-maker in London; but Dr. Hooke has diſputed the priority of the invention, and has affirmed that he exhibited a pendulum with what is now known by the name of the *anchor* eſcapement, to the Royal Society of London, in the year 1666, ſoon after the great fire of that year. We will not endeavour to ſettle the point that relates to priority of invention, but proceed to deſcribe the contrivance itſelf, which has continued, and is likely to continue, to be of permanent

uſe in ordinary clocks. *Fig.* 3. of our laſt named plate is the repreſentation of the anchor eſcapement, as it is commonly conſtructed for a pendulum clock that ſwings ſeconds, which pendulum, in conjunction with the anchor eſcapement, gained the appellation of the *Royal pendulum.* The eſcapement, or ſwing-wheel A, has uſually thirty teeth, when a vibration is performed exactly in a ſecond, in which caſe a ſecond's hand is uſually inſerted on its elongated pivot, to indicate ſeconds; but if no attention is intended to be ſhewn to the indication of ſeconds, the train may be made to admit of any other convenient number of teeth; B C is the anchor and pallets, taking its name from a reſemblance to a ſhip's anchor, that may be obſerved in its ſhape; the diſtance from its centre of motion a to that of the wheel b is determined by the number of teeth that the pallets take in between them, it being eſſential to the freedom of action that two lines, drawn from the two centres of motion a and b, ſhould conſtitute a right angle at each of the two points of action, as ſeen included by the dotted lines, meeting at the ends of the acting teeth d and e: in the pallets which we have made to include nine teeth, the centre of the pallet's motion falls at the point a, but if they were made to include eleven teeth the ſaid point would fall above at h; and if they included fewer than nine the point for the centre of motion would fall below a: in general ten or twelve are contained between the pallets of a ſecond's pendulum, but this muſt depend on the arc that the pendulum is intended to vibrate; for the more teeth are taken in, the greater is the diſtance of the two centres of motion, and conſequently the ſmaller the angle or arc of action on the pallets. If a circle $f g$ be deſcribed by a radius equal to half the diſtance of the centres of motion $a\,b$, round the point a, the two faces of the pallets B and C uſually lie in the tangent lines $e\,i$ and $d\,g$ of that circle, which lines are the guides for making the ſlopes. The action of the eſcapement before us may be explained thus; ſuppoſe the tooth d, ſeen reſting on the ſlope of pallet C, to be urging this pallet outwards from the centre of the wheel, by which a motive force is applied to the moving pendulum through the medium of the crutch; preſently it eſcapes, and pallet B is brought inwards towards b, ſo as juſt to avoid the tooth e; the wheel is now at liberty to move, and goes on, by the force of the maintaining power, till the ſucceeding tooth k falls on the ſloped face of pallet B, which is now urged outwards, and endeavours to give a contrary motion to the pendulum; but the momentum of the moving pendulum is too powerful for its impulſe, and carries the tooth k back again till the momentum is expended, at which inſtant a recoil of the wheel and ſecond's hand placed on its arbor take place; preſently the pendulum returns, and the tooth k now puſhes it on, and eſcapes; the pallet C is now brought back, ſo that the tooth following d falls on its ſloped face, and in its turn experiences a recoil till the pendulum returns, when it puſhes on and eſcapes; then another tooth next after k falls on the face of B, and experiences the ſame recoil and ſubſequent power of eſcapeing that the others did; and thus the alternate vibrations of the pendulum are perpetuated as long as the maintaining power continues. The effect of this eſcapement on the pendulum is ſimilar to that of the crown-wheel eſcapement on the balance; the pendulum is either accelerated or retarded in every part of its vibration, except during the almoſt inſenſible inſtant of the drop of the ſucceeding tooth, when one has eſcaped; but as the momentum of a heavy pendulum in motion is greatly exceeding that of a balance in motion, the bad effect is ſmaller in degree. When an additional weight is added to the weight conſtituting the maintaining power, the arc of vibration is increaſed, whence one might be led to expect a retardation in the time of a vibration, the arcs being circular; but the fact is, that the vibration is accelerated very ſenſibly by means of the pendulum being both accelerated in its deſcent and oppoſed in its aſcent, and the pendulum comes ſooner back than gravity alone would bring it. Here then the compound law of motion differs from the ſimple law of gravity, but not in the ratio of the arcs to the ſines of the angle of vibration; for if the compound law were to the ſimple law of gravity as the *arcs* are to their *ſines*, the vibrations would be iſochronal, whatever their extent might be. It is hardly neceſſary to add that this eſcapement is one of the firſt claſs.

12. *Graham's dead-beat.*—The dead-beat eſcapement, as originally contrived by Graham, is a modification of the anchor eſcapement we have juſt deſcribed, from which it differs only by taking off a part of the ſlope of each pallet, and by making the pads, that is, the back of one pallet and interior part of the other, portions of circles deſcribed from the anchor's centre of motion, ſo that when the point of a tooth reſts on thoſe parts, while the pendulum is finiſhing a vibration, no recoil takes place, but the wheel continues motionleſs, or, as it were, *dead.* *Fig.* 4. of the ſame plate gives the figure of the dead-beat eſcapement-wheel and pallets, where we have repreſented the wheel, as we did the wheel of recoil, with only four inſtead of ſix radii, that there might be more ſpace for our geometrical lines. In this conſtruction, as in the preceding one, the diſtance of the centres of motion a, b, is determined by the tangent lines meeting the radii at the points of the acting teeth; when this diſtance is an exact diameter of the eſcapement wheel, we find that the pallets take in juſt ten teeth out of thirty, which is the caſe in the figure before us, but when twelve teeth are taken in, the centre of the anchor's motion falls at h, juſt a diameter and a half from the centre of the wheel; and this is Berthoud's rule for giving the diſtance $a\,b$ without any reference to the tangent and radius; for he has found that the arcs of action on the ſlopes of the pallets $a\,m\,n$, and $a\,o\,p$, are each only one degree, but that if fewer teeth than twelve were included between the pallets, the anchor would be ſhorter, and the arcs of action proportionally longer. This rule might be a good one with a given maintaining power, that is, where the whole arc of vibration is of a given extent, but it does not follow that one degree for the arc of action before the eſcape is the beſt in all caſes where the motive powers vary. We are of opinion that experiments might be inſtituted to aſcertain this important point, by applying various weights ſucceſſively, firſt with pallets that have twelve teeth included, and then with ſuch as have eleven, ten, &c. but the experiment could not go beyond 14 teeth, becauſe when half the wheel is included the tangent becomes a vertical line, parallel to the line of diſtance $a\,b$, and therefore this diſtance becomes *infinite.* There is probably a certain maintaining power that is beſt for a certain angle of action, with a pendulum of a given weight, but that does not ſeem to have been aſcertained either by calculation or experiment hitherto. The thing to be aimed at is, to make the compound law of the pendulum's motion ſuch that the varying forces may accelerate or retard it in proportion to the arcs of diſtance from the loweſt point, which is the caſe with the ſimple law of gravity, as it regards the *ſines* of the ſaid arcs. We have put the ſame letters of reference to our preſent figure as to *fig.* 3, that the reader may the more eaſily comprehend the correſpondence between them, and to prevent the neceſſity of further minute deſcription of the parts; the ſlopes of the pallets being determined by the ſame tangent lines $e\,i$ and $d\,g$, as before. We ſhall, therefore, confine the remainder

of our deſcription to the features that differ, and to the mode of action depending thereon. The circle B C, paſſing the points of the firſt and eleventh teeth, including the ten ſpaces between the pallets, forms the interior faces of the ſaid pallets B and C, and the exterior portions B *e* and C *d* are formed by a concentric circle of larger radius. Theſe circles are deſcribed from the point *a*, or centre of the anchor's motion, therefore a tooth reſting at any time againſt any one of thoſe circular portions remains without recoil; the diſtance between the ſaid circles is ſomewhat leſs than one-half of the ſpace contained between the extreme ends of any two contiguous teeth, and the nearer it is to one-half of a ſpace, the ſmaller will be the drop after an eſcape, or, as the workmen ſay, the cloſer the pallets will be laid. The teeth are ſomewhat varied in ſhape from the inclined teeth of the recoil eſcapement, a portion of the ſlope at the bottom being cut away, that the end of the pallet may enter the ſpace, when the pendulum vibrates beyond the arc of action, without coming in contact with the metal of the wheel, which would make the pendulum rebound, and diſturb the regularity of the vibration. Theſe obſervations being premiſed, the reader will now be prepared to comprehend the action. The tooth at *e* has juſt paſſed the ſlope of pallet B, and is eſcaping, after having given its ſtroke or impulſe gradually, in ſliding along the ſlope from *e* to its preſent ſituation; the pallet B is now going from the centre of the wheel's motion *b*, and the pallet C is come back from its excurſion, in time to allow the tooth *b* to fall on its inner circular part, near the angular point of the ſlope; the pendulum goes on in its vibration till its gravity overcomes its momentum, during which time, the pallet B is no longer in contact with the wheel, but the pallet C enters the ſpace between *b* and *d*, and the point of the tooth *b* reſts on the inner circle of the pallet; preſently the pendulum returns, the point of tooth *b* ſlides back again till the ſlope *b d* preſents itſelf, when urged by the maintaining power, it eſcapes after having made its puſh to the pallet C, which now continues its motion outwards, and conſequently pallet B falls in the way of the tooth *k*, which follows, but which reſts on the exterior circle B *e* of this pallet, till the pendulum returns as before; it then meets the ſlope at *e*, and, giving its puſh to the pallet, eſcapes, as its preceding tooth had done; and thus the vibrations are alternately aided in future, while, as has been ſeen, one tooth only completely eſcapes at the interval of two vibrations: which is the reaſon why a wheel of 30 teeth is proper for the indication of 60 vibrations of a ſecond's pendulum. When the wheel is made of hardened ſteel, and the pallets of ruby or agate, the friction is greatly diminiſhed, and will admit a ſhort angle of action, or diminution of power.

13. *Modification of the dead beat by Grignon.*—When we gave the "Hiſtory of the ſucceſſive Improvements in Clocks," under our article Clock, we ſaid that the ſenior Thomas Grignon, of Covent Garden, London, improved the dead-beat eſcapement of Graham, and preſented a clock to the Society of Arts in 1759, which remains in one of their rooms to this day, that has got this improved eſcapement, the peculiar property of which is ſaid to be, that it performed alike with *four* and with *twelve* pounds ſuſpended as a maintaining power; if this is a fact, the eſcapement muſt have the property, ſo much deſired in all eſcapements, of rendering all the arcs of vibration iſochronal. We have been favoured with a manuſcript account of this eſcapement, and of its principle of conſtruction. It will be doing but juſtice to the memory of departed genius, if we give the author's own figures, demonſtration, and account of his improvement, as he has left it in his own hand-writing. *Fig.* 5. *of Plate* XXXII. is the *ſcheme*, and *fig.* 6. the *demonſtration*, as the author himſelf has intitled the figures, the latter of which has no letters of reference, but is ſufficiently intelligible in conjunction with the other. "It appears from the ſcheme," ſays the author, "that the diſtance of the centre of the pallets from the centre of the ſwing wheel in that machine (at the Adelphi) is *one whole diameter* of the wheel, which has this peculiar excellence, that the triangles formed at the ends of the pallets, by drawing the tangents for the ſlopements are *equal*; (nor indeed can they ever be equal, continues he, where the diſtance is more or leſs than *one whole* diameter of the ſwing wheel,) and, on the contrary, where that diſtance is duly obſerved, all the triangles will ever be equal; for then all the interſections, made by drawing the two tangents to the circle of the pallets, will fall exactly alike, (*fig.* 6.) interſecting the intermediate circle, as may be ſeen by the figure, conſequently the tangent lines, together with the chord of the ſwing wheel form a rectangled triangle, the upper angle of which, by altering the ſlopement only, changes its place in the circumference of the circle, the ſame chord always continuing its baſe. For a farther demonſtration of which, ſee 21ſt propoſition of the the 3d book of Euclid.

"Again, when the diſtance is duly obſerved, we ſhall find that one of the lines for the ſlopement of the pallets will be the hypothenuſe, and the other the perpendicular of rectangled triangles, whoſe baſes are equal to 120°, the halves of which muſt be 60°. That they are rectangled triangles may be eaſily proved; for if the baſe be 120°, and perpendicular 60°, the hypothenuſe muſt be 180°. See 1ſt Prop. of the 12th book of Euclid."

In another manuſcript paper, Mr. Grignon ſays, "that the teeth of the ſwing wheel have an equal effort, when they act upon the ſlopements or faces of the two levers or pallets, may be thus demonſtrated.

"Draw the lines A, A, upon the faces or ſlopements of the pallets or levers *a*, *a*, now theſe are the lines of direction; let fall the perpendiculars B, B, from the centre of motion of the pallets C; now, I ſay, that if you meaſure the lengths of theſe perpendiculars, they give you the efforts of the arms of the levers or pallets D C, D C; for by the 9th prop. of Mr. De la Hire's Treatiſe of Mechanics, the efforts of a weight or power are not to be meaſured by the length of the arms of the levers, but by perpendiculars drawn from the hypomochlion upon the lines of direction of the weight or power. That theſe levers are equal is thus proved; for, taking C for your centre, deſcribe the circle E E E; now if the perpendiculars B, B, are both radii of the circle E E E, they muſt, of conſequence, be equal, which is what was to be proved. Again, that the faces or ſlopements of the pallets or levers are equal may alſo be thus proved: *a* A, *a* A, are the lines of direction of the action of the teeth, and being both tangents of the ſame circle E E E are conſequently equal."

The remarks that have occurred to us on contemplating Mr. Grignon's *ſcheme*, as he has called it, are, firſt, that his diſtance between the centres of motion require *ten teeth* out of thirty to be taken in by his pallets, as we have ſhewn in our laſt article; ſecondly, the circle E E E is deſcribed with leſs than half the diſtance of the centres, and is yet made the circle to which the tangents are drawn, that form the ſlopes, the reaſon of which he has explained, the radius C B of this circle, it appears, muſt be determined by a line *a* A, drawn parallel to the line of diſtance, which muſt be a tangent to the ſaid circle, and which affords an eaſy and practicable mode of drawing the ſlopes agreeably to this conſtruction; thirdly, if the ſlopes thus formed by tangents drawn to a diminiſhed circle have the iſochronal property, they are worthy of future imitation, under the circumſtance particularly of ten teeth being included between the pallets; and laſtly, we obſerve, that the *ſame circle* forms the *exterior* curve of one pallet, and the *interior* one of the other, which is not the caſe with Graham's pallets, but which certainly makes the friction alike on both pallets, ſeeing the circular ſurfaces rubbed by the points of the wheel's teeth are at equal diſtances from their common centre of motion. Theſe conſiderations are all in favour of Mr. Grignon's modification of the dead-beat eſcapement, as each excurſion of the pendulum muſt be influenced by ſimilar circumſtances, and if moreover it poſſeſſes the iſochronal property attributed to it, it is ſomewhat remarkable, that the Adelphi ſociety have been labouring to reward inferior eſcapements in great variety, while one of the beſt *dead-beat* eſcapements is beating *dead* to the ſociety, having *eſcaped* their notice, while performing its functions within their own walls.

14. *Mr. Bennett's modification of the dead-beat.*—Mr. J. Bennett of Norwich has publiſhed an account of what he conſiders an improved method of deſcribing the curves and faces of Graham's dead-beat pallets (ſee Nicholſon's Jour. vol. xv. 8vo.) which account we think deſerves a place here in common with Grignon's method.

Draw the line A B (*fig.* 7. *Plate* XXXII.) ſays the author, on which deſcribe the circle B, the ſize of the intended ſwing wheel; then, according to the number of teeth the pallets are intended to eſcape over ſay, as 60 (the double of the number of the wheel's teeth) is to 360°, ſo is double the number intended and one more to that proportion; thus, ſuppoſe the number intended to eſcape over nine, the double of which is 18, to which add one, and there are 19; then ſay,

As 60 : 360° :: 19 : 114°; the half of 114°, which is the whole arc included, is 57°; then on the circle already drawn ſet off on each ſide of the line A B 57°, from which points draw lines to the centre of the circle; then on theſe points where the circle is croſſed erect perpendiculars, which will interſect at the centre of the pallet's motion in the line A: from this point as a centre draw the arc C C, to cut the points where the radial lines cut the circle; the arc thus drawn deſcribes the receiving and leaving pads of the pallets. The inclination or inclined plane of each pallet muſt form an angle of 60° with the ſaid radial lines; thus from the points of interſection, near E and G, draw the ſmall ſemicircles D and G with any radius, and ſet off 60° from *f* to *g* on the ſemi-circle D, and from *h* to *m* on the ſemi-circle G, then will lines drawn from the centres of the ſemi-circles, through the points *g* and *m* reſpectively, give the proper direction of the ſlopes of the pallets' faces.

This conſtruction is very ſimilar to Grignon's, though differently projected: the centre of motion A is determined in the uſual way, and the odd unit given to double the number of teeth included is an allowance for the breadth of the pallet, to have as little drop as poſſible; the ſlope of the pallet G is parallel to the line A B, in Grignon's conſtruction, but is not quite ſo here, for the difference of the angles at the oppoſite ſides of the radial line is $\overline{60^{\circ}-57^{\circ}}=3^{\circ}$, which is what theſe lines want of being parallel, which quantity of deviation ſeems to conſtitute the principal difference between the two conſtructions; if the radial line of pallet G had been drawn to the lower point of the pallet, ſo as to have made the angle at the centre 60°, and the teeth included had been exactly ten, then the two methods would have coincided, and the point A of the pallets' motion would have been an exact diameter of the wheel from its centre. We conceive that the effects of the two conſtructions may be ſo nearly alike, that their difference in practice may be almoſt imperceptible. If there is any difference, varying the maintaining power conſiderably in different trials will detect it, by rendering the alterations in the rates perceptible from the compariſons. Otherwiſe the alternate angles might each have been 57°, inſtead of one of them being 60°.

15. *Iſochronal eſcapement for a pendulum.*—So long ago as about the year 1720 Saurin, Julien le Roy, and Enderlin, wrote memoirs on the nature of the curve that was neceſſary to give to the pallets of an anchor, inſtead of the concentric circles, in order that the ſwing wheel may have juſt ſo much recoil only, as will render all vibrations, performed in arcs of different extent, iſochronal; and ſince their time Berthoud in France, Reid in Edinburgh, Melville and others in London, have put in practice a method of conſtructing pallets founded upon the ſame principle. We think it not improbable, however, but that the Scotch and Engliſh artiſts have borrowed their contrivance from the French author, who publiſhed his conſtruction in his "Eſſai ſur l'Horlogerie" in the year 1786, before which time we do not find any traces of an iſochronal eſcapement except Grignon's juſt deſcribed, and Smeaton's, which follows. The conſtruction of the eſcapement in queſtion differs from the dead-beat only in one particular, which is, that the circular portions of the pallets, which in the dead beat are concentric, deſcribed from the centre of the pallet's motion, in the iſochronal eſcapement are *excentric*, with reſpect to each other, thoſe curves on which the ends of the teeth of the ſwing wheel reſt being deſcribed from points out of the centre of motion. Berthoud had made ſeveral experiments with different eſcapements, and different maintaining powers, from which he found that the ſame addition to the power which accelerated the vibrations of the pendulum, when a recoil eſcapement was uſed, retarded the ſame when a dead-beat eſcapement was ſubſtituted; hence he concluded that there muſt be a medium between much recoil and no recoil, which would make the pendulum vibrate in the ſame time in all arcs, or, which is the ſame thing, with any addition or diminution of the maintaining power; he therefore fixed, after various trials, on a conſtruction producing but a *ſmall recoil*, which anſwered his moſt ſanguine expectations, and which we ſhall be happy to deſcribe here, particularly as it promiſes to anſwer a better purpoſe than the common dead-beat, which has been long in high eſtimation; and as it has not, we believe, been deſcribed by any Engliſh author. *Fig.* 1. of *Plate* XXXIII. is a plan of Berthoud's iſochronal eſcapement, where A, as before, is the ſwing-wheel, B and C the pallets of the anchor, and *a* the centre of their motion; the diſtance of the centres *a*, *b* alſo, as before, depending on the number of teeth taken in by the pallets; the angles *m a n* and *o a p*, are the angles of action by which Berthoud has given his ſlopes of the pallets without the tangent lines *e i*, and *d g*, but we have thought it right to ſhew how they may be given both ways. Berthoud's method of ſloping to ſuit any angle previouſly given is more extenſive in its application, but the quantity and direction of the impulſe will vary as the angles *m a n*, and *o a p*, vary; whereas the method of ſloping by the tangent lines can only vary by varying the circle *f g*, as Grignon has propoſed: in our plan we have taken the circle's diameter equal to the diſtance *a b* of the centres for the ſake of uniformity of plan, that the reader may ſee how the pallets, ſo formed, differ in ſhape from the dead-beat pallets. The exterior portion of the circle *d* C, of pallet C, is deſcribed with the extent *a d* from the centre *a*, but the interior portion *b* 4 is deſcribed with the ſame extent from a point

below the centre; the difficulty conſiſts in determining the true ſituation of this excentric point 5; Berthoud's rule, founded on the reſult of experiments, is this; having determined the breadth of the pallets, equal to ſomewhat leſs than half a ſpace of the ſwing-wheel, deſcribe from *b*, in the line *a p*, the concentric dotted circle 1, 2, 3, &c. ſet the diſtance between the two concentric circles, or breadth of the pallet, *three times* over along the inner curve to 1, 2, and 3, then in a direction from 3 towards *a* ſet the ſame *once* to 4; in the next place, with the extent *a b* find the point 5 by interſection from the points *b* and 4, and this point 5 is the excentric point deſired, from which the curve *b* 4 is deſcribed with the extent *a b* as before, which is the interior curve to be ſubſtituted for the concentric curve 1, 2, 3 of the dead-beat eſcapement; and it is evident that while the pendulum is in motion inwards, with a tooth reſting on this excentric curve, the wheel muſt have a certain recoil. Again, the exterior curve of excentricity, of pallet B, is thus deſcribed; the curve 1, 2, 3, &c. is deſcribed, from the point of the tooth that is in the line *a m*, and the points therein are taken as before at the diſtance from each other of the breadth of the pallet, or at ſomewhat leſs than half a ſpace of the wheel; the point 4 is here ſet outwards in the direction from *a* to 3; then with the extent *a e* the excentric point 6 is determined by interſection from *e* and 4, which point is above the centre; laſtly, with the extent *a e*, as before, deſcribe the excentric curve *e* 4 from the point 6, which being ſubſtituted for the concentric circle 1, 2, and 3, will produce a ſimilar recoil in the pallet B, as the curve *b* 4 produces in pallet C. The inner curve of pallet B having no action, like the outer curve of pallet C, may be deſcribed from *a*, or be a ſtraight line. The writer of this article has a half-ſecond's pendulum clock with this eſcapement, and Troughton's tubular pendulum, which goes admirably with any power that will keep it in motion.

16. *Smeaton's eſcapement of the turret-clock at Greenwich.*—The eſcapement which Mr. Smeaton contrived for the turret clock at Greenwich reſembles the iſochronal eſcapement, which we have juſt deſcribed, in a certain degree, and was, no doubt, intended to anſwer the ſame purpoſe. *Fig.* 2. of *Plate* XXXIII. contains the plan of this eſcapement, in which A B is the radius of the eſcapement wheel; B C a tangent line at $3\frac{3}{4}$ teeth from the vertex, drawn from C, the centre of the pallet's motion; B D E is a circle deſcribed from the centre C through the points B and E, which are each $3\frac{3}{4}$ teeth from the vertex; F G is a line drawn parallel to the vertical line A C at the diſtance from the vertex of $3\frac{1}{2}$ teeth, and cutting the circle B D E in the point G; then G C B is half of the angle of vibration, and ſetting off the arc B H = B G, G C H will be the whole angle of vibration. Draw the line C H cutting F G in I, and through the point G of this pallet from the centre A deſcribe a circle that may cut the radius A K in the point K; this will be the point of the other pallet; the line E C being alſo a tangent to the wheel at $3\frac{3}{4}$ teeth from the vertex. Now ſetting off K L on the circular arc = G H, the angle of vibration K C L will be equal to the other angle of vibration G C H, and if through the point L the line C L be produced, and L M be ſet off = I H, then will the wheel move equally forward, by a ſimilar motion of each pallet. Again, with the radius K C, upon K as a centre, deſcribe the arc C N, and alſo with the ſame radius from the point M deſcribe the interſecting arc O P; then from Q, the point of interſection with the radius unaltered, deſcribe the curve through the two points K and M to R, which curve will give the working face of the pallet that will produce a ſmall recoil nearly equal to that produced by the plane G I; in this conſtruction the depth of the teeth is equal to a ſpace contained between two contiguous teeth, and the acting ſide of the tooth is a portion of a circle deſcribed from the bottom of the ſloped ſide of the *fifth tooth* incluſive. The circle to which the ſlope of the tooth is a tangent is $\frac{1}{6}$th of the diameter of the wheel. When the ſwing-wheel has a greater number of teeth than 30, $7\frac{1}{2}$ teeth are ſtill contained between the pallets, and the centre of their motion is determined, as in the former conſtructions, by a tangent line drawn from the point of the acting tooth. The two ends of the anchor may be made more apparently equal in length by letting the pallet K eſcape over $3\frac{1}{4}$ teeth and the pallet G over $4\frac{1}{4}$, in which caſe the arc B D will be of a greater radius than the arc N D. The ſteel pallets or end-pieces are fixed by ſcrews that allow an adjuſtment for diſtance or depth of the pallets, ſo that they may be detached, newly formed, and replaced, at any time after they have been in uſe.

17. *Eſcapement with two levers by De Bethune.*—Thiout ſays that De Bethune was the firſt contriver of the clock eſcapement with two detached levers, and that the origin of this conſtruction was derived from the eſcapement of Dr. Hooke, or of a German artiſt, with two balances, which we have deſcribed. Thiout made the firſt of his in the year 1727, and ſays that from that time the eſcapement with two levers became common among clock makers in France. *Fig.* 3. of our laſt plate is a repreſentation of this eſcapement as made for a pendulum; where A and B are the two levers placed faſt on each a ſeparate arbor included within the frame; to the lever B is attached the crutch or fork that communicates with the pendulum not ſeen, and the fork C which is viſible in the figure; the lever A has a bar of metal D faſt to it, that carries the roller E, of a diameter equal to the aperture of the fork C; and the ends of theſe levers conſtitute the pallets placed at the diſtance from each other of five out of thirty teeth of the ſwing wheel. During the action of this eſcapement, when one of the levers is acted on by a tooth, the roller and fork are raiſed up, and the other lever becomes a detent to the wheel; then when at the next vibration the other lever is acted upon, the roller and fork are depreſſed, and the firſt lever in its turn becomes a detent; and thus the vibrations are alternately aſſiſted while the maintaining power continues to actuate the ſwing wheel. This eſcapement has a recoil, and Julien le Roy diſcovered (Memoire ſur l'Horlogerie par M. le Roy, fils ainé de Julien le Roy, 1750) that when the levers are each the exact length of the radius of the ſwing wheel, it poſſeſſes the iſochronal property, that is, all arcs of vibration will be performed with it in the ſame time. We are not aware that this eſcapement was ever made in England.

18. *Dead-beat eſcapement for a pendulum by Amant, (a cheville)*—*Fig.* 4. of the ſame plate ſhews the plan of an eſcapement by Amant, formerly a clock-maker at Paris, that has an eſcapement wheel without teeth, but with pins or pegs inſerted in a concentric circle in the plane of the wheel, as appears in the figure; the pallets A and B are both faſt to the verge or arbor of the crutch, in the uſual way, and are brought ſo nearly together that the ſame pin that ſlides along the ſloped face of one pallet B immediately falls on the inner circle of the other pallet A, and continues without recoil till the pendulum has made its vibration; at the return of the pendulum the pin meets with the ſloped face of pallet A and eſcapes; then the next pin falls on the interior circle of pallet B, and remains without recoil till the pendulum returns from its vibration, when it ſlides down the ſlope and gives a puſh to the pallet as the firſt one did before; thus the two pallets are alternately actuated by the ſame pin before

its final eſcape, and ſixty vibrations are made during one revolution of the plate with thirty pins. The ſlopes appear to ſtand at right angles to each other, but it is not ſaid, in the account we have ſeen, how either of the ſlopes ought to be drawn geometrically. This is the kind of eſcapement at preſent uſed in the large turret clock at Hampton Court, and we have ſeen many other clocks in England with a ſimilar eſcapement, which, we have no doubt, may perform as well as with the ordinary dead-beat eſcapement as originally conſtructed by Graham, provided the drop from the firſt to the ſecond pallet, which muſt neceſſarily be equal to the thickneſs of the pin, do not produce a jerk that may affect the vibrating pendulum.

19. *Dead-beat eſcapement* (*a cheville*) *by J. A. le Paute.*—In Le Paute's "Traité d'Horlogerie," publiſhed at Paris in 1755, is an account of a dead-beat eſcapement as made by him for a clock, which differs from our laſt by Amant only in its mode of poſition, and which therefore requires no figure for its deſcription; the levers of the two pallets open like a pair of dividers to any extent, but are not in the ſame plane, one of the levers being over the anterior plane of the pin wheel, and the other over the poſterior plane; hence two ſets of pins are neceſſary, one on each plane; but the action is the ſame as we have deſcribed it in Amant's eſcapement, which it probably excels inaſmuch as the drop may here be made as little as poſſible, becauſe the ſame pin is not required to paſs between the ends of the pallets in eſcaping; but one pin acts only with one pallet before it eſcapes; there are conſequently ſixty pins in all, thirty on each plane of the wheel.

The ſame author alſo publiſhed an account of a watch eſcapement with pins (a cheville) which the reader will find deſcribed at page 198 of the ſame treatiſe.

It is eaſy to conceive, after what we have ſaid about the iſochronal pallets, that both Amant's and Le Paute's eſcapements, and indeed all the dead-beat eſcapements, may be made to have a little recoil, ſo as to become of the iſochronal kind, provided the acting concentric circles of the pallets were made in a certain degree excentric; that is, if they were deſcribed from points out of the centre of motion of the pallets themſelves. The only difficulty is in determining the ſituation of thoſe points under different circumſtances, which we think is a fair object for future experiments.

20. *Harriſon's clock eſcapement.*—The eſcapements which we have hitherto deſcribed require oil on the pallets, to diminiſh the friction of the parts that rub againſt one another in action; but the eſcapement we are now going to deſcribe as the invention of the ingenious Harriſon requires no oil, on account of his conſtruction being free from rubbing at the time of the pallets' action. *Fig.* 5. of *Plate* XXXIII. exhibits the ſhape of Harriſon's eſcapement. G D O is a portion of the ſwing wheel, moving round M as a centre: A is the verge or arbor of the crutch that communicates with the rod of the pendulum; to this are attached the pallets, each conſiſting of a long and a ſhort lever with a joint at the place of union; the ſhort lever A B is faſt to the arbor or axis of motion, and carries the longer lever B C which has a claw or hook *a* C, and a ſlender ſpring is ſo applied as to keep theſe two levers nearly at right angles to each other; at right angles to A B is alſo the other ſhort lever A E faſt likewiſe to the axis of motion, and bearing the longer lever E F, as A B bears the lever B C; the joints are at B and E, and a ſimilar ſmall ſpring holds the levers A E and E F in like manner at right angles to each other, when not otherwiſe acted on. The lever E F has not only a claw, like the other long lever, but a heel to it, or projecting part *f*. The action of this contrivance may be thus explained; ſuppoſe the tooth D urging the pallet or claw C, while the pendulum is moving towards the right hand in its excurſion; this preſſure of the tooth produces a tendency in the lever B C to move round, but the joint at B yields, and opens the angle A B C a little; during this motion round A, the ſhort lever A E is lowered a little, and with it the long lever E F, which we will call the detent; its claw F therefore falls in the way of the tooth G, which now drops on the back part of the claw, and is inſerted into a notch under the projecting heel *f*; the further motion of the pendulum, and conſequent depreſſion of the ſhort lever A E, carry the end of the tooth G back again till the vibration is finiſhed, and produce a recoil. At the moment when the tooth begins to have a recoil, the tooth D at the pallet or claw C is withdrawn and eſcapes; the ſlender ſpring of the lever B C, which had been bent from its quieſcent ſtate, now reſumes its original ſituation, and throws out the lever B C, till its angle formed at B is again nearly a right angle; in the mean time the wheel is detained by the heel of the detent E F, in which ſituation it oppoſes the vibration through the medium of the two levers E F and E A, which are attached to the crutch of the pendulum. The vibration being finiſhed, the pendulum returns towards the left, and the wheel is at liberty to advance again; the preſſure of the tooth G on the claw of the detent now aſſiſts the vibration through the arc of eſcapement or arc of action, and cauſes the pallet C to approach the wheel, till the tooth following D falls on it and experiences a recoil in its turn. This recoil ſets the detent F at liberty from the preſſure of the tooth G, which now flies back by means of its ſlender ſpring to its rectangular ſituation, as it regards the ſmall lever A E: preſently this vibration terminates and the pendulum returns, while the tooth following D aids its vibration by pulling forwards the pallet C, when the proceſs of making two ſucceſſive vibrations is gone through, and the ſame operation is repeated. The reader will have obſerved in this account that the tooth and pallet, or tooth and detent, do not *ſlide* on one another, but give each other a *direct puſh*, or pull, the buſineſs of the ſmall ſprings being to remove them from contact by one ſudden leap, where rubbing is altogether avoided, which contrivance ſuperſedes the neceſſity of having oil applied to the pallets, and is certainly an ingenious contrivance, as well as uſeful in practice. It muſt be obſerved, however, that the recoil, ſuch as it is, takes place at the extremities of the vibration, when the momentum of the pendulum is almoſt exhauſted, and is therefore the moſt unfavourable part of the vibration to occur in; notwithſtanding which diſadvantage the eſcapement has performed as well as any other that had preceded, perhaps as well as any that has followed it, as the regulator to which it was applied has ſeldom if ever been excelled in ſteadineſs and accuracy of performance for fourteen years of uninterrupted ſucceſſion. The imperfection ariſing from the recoil taking place at the extremities of the vibrations ſeems to have been compenſated by the immenſe momentum of the pendulum that this eſcapement admitted of with a comparatively ſmall maintaining power, while the abſence of friction and of oil gave it the advantage of permanently uniform action. Of courſe the pendulum was of the grid-iron form, that compenſated the effects of varying temperature, and allowed the eſcapement to have its merit appreciated. The report of the performance of Harriſon's regulator with the eſcapement in queſtion was, that it did not vary *one ſecond* per day from any preceding or following day for the ſpace of fourteen years, and that the aggregate of the variations from true mean time did not amount to half a minute.

Haley alſo conſtructed clock pallets that required no oil, but as none of them have fallen under our notice, we pretend not to ſay how they differed from Harriſon's.

21. *Eſcapement by Alex. Cumming for a clock.*—Mr. Cumming publiſhed his elements of clock and watch-making in the year 1766, in which, among other matters, he deſcribes a conſtruction of an eſcapement of his contrivance, that removes the friction and influence of oil not only during the time of reſt of the pallets, but alſo during the motion of the ſwing wheel, ſo far as they can influence the vibrations of the pendulum; and alſo obviates all the irregularities that can poſſibly ariſe from the maintaining power as tranſmitted through the train. *Fig.* 6. of *Plate* XXXIII. exhibits as much of this eſcapement as is neceſſary for explaining its general action, but thoſe readers who wiſh to ſee all the minutiæ of the conſtruction, as repreſented by different plates of ſections, muſt have recourſe to the book itſelf, as the complexity of the parts repreſented in various points of view demands more minute repreſentation than our plan admits of. Our figure is a copy of plate 5 of the author, in which A B C is the eſcapement or ſwing-wheel; D E the pallets ſeparately moveable on the axis of motion, and having each a little ball or weight H and I reſpectively ſupported by horizontal arms; each pallet with its attached weight is ſeparately moveable from the other round its reſpective axis of motion, ſo that when one is raiſed by the wheel the other remains at reſt; F and G are two detents firmly attached together, like the ordinary pallets of a common dead-beat or recoil eſcapement, and are fixed to a cylinder of braſs P P, that ſurrounds the two axes of motion of the pallets, which are in the ſame ſtraight line but ſeparated from each other at the middle of the cylinder, where is a partition that bears the interior pivot of one axis and the exterior one of the other; the crutch of the pendulum is alſo faſt to the cylinder; ſo that the two detents and crutch move together along with the cylinder, without the motion of either pallet; and each pallet can move ſeparately without the detents and crutch. M is a load to counterpoiſe the detents and crutch in any poſition given them; and *n o* are two pins carried by the pendulum that project far enough to fall alternately in the way of the arms that carry the balls H, I, as the pendulum vibrates.

To explain the action of this eſcapement, let us ſuppoſe the pallets D and E, the detents G and F, the crutch L, and pins *n* and *o*, together with the balls H and I to be exactly as repreſented in the figure, where the lever of the detent G is hid behind the lever of the pallet E, but may be conceived to be parallel to it, the pallet D having been previouſly lifted from its quieſcent poſition, where its point reſted on the rim near the foot of tooth A; then if we conceive the pendulum moving from right to left with the ball I urging the pin *o* attached to an arc fixed to the pendulum, or crutch of the pendulum, the vibration is aided by the gravity alone of this ball. The arc, that bears the pins *n* and *o*, has a contrivance not ſeen in the figure for unlocking the detents at the moment when either of the pins bears againſt its ball, which contrivance it will be ſufficient for our purpoſe to call Z. Conceive now the pin *n* brought into contact with the arm of ball D by the moving pendulum, the detent F is unlocked, and the tooth A of the wheel quits the end of pallet D; the ball H now acts by its gravity on pin *n*, and deſcends, at the ſame time aiding the returning vibration, while the pallet D, united to the arm of ball H, deſcends alſo towards the wheel; but as ſoon as the pendulum firſt began its original vibration, the pin *o* was withdrawn from the preſſure of the ball I, by means of the attached pallet E falling on the tooth C of the wheel, ſo that all the latter part of the vibration was free; this preſſure of pallet E on the tooth C diminiſhed the preſſure of tooth A on the detent F at the inſtant of the unlocking, which we have mentioned; the wheel now in motion by the action of the maintaining power, (through the medium of the train,) goes on till the tooth C, acting on the pallet E, raiſes it outwards, together with its attached ball I, till the detent G ſtops the wheel's motion, when all the parts are at reſt till the pendulum nearly finiſhes its returning vibration, and then its pin *o*, meeting with the elevated arm of ball I, preſſes againſt it and concludes the vibration; at the moment this preſſure is felt the contrivance Z unlocks the detent G, and allows the tooth C to eſcape; in the mean time the ball I by its gravity urges the pendulum for a ſhort time, while the tooth following A, meeting with pallet D, raiſes it and the ball H a ſecond time, the tooth following C comes in the way of pallet E, and ſtops the further action of the ball I on the pendulum, which now vibrates, as before, free, till its pin *n* again meets with the arm of ball H, when the ſame proceſs is repeated; and thus the weights H and I are alternately raiſed by the wheel, and then alternately act for a ſhort time on the pendulum, at the beginning of each vibration, ſo that gravity alone is properly ſpeaking the maintaining power of the pendulum, and whatever may be the maintaining power of the train, it never affects the motion of the pendulum; but only raiſes the balls, that afterwards act on the pendulum by their gravity alternately exerted from a ſtate of reſt. Thus, whatever may be the effects of oil, duſt, friction, wear, &c. on the action of the train of wheel-work, as it has no immediate connection with the pendulum, except during the ſmall inſtant of unlocking the detents, theſe effects are almoſt entirely avoided, as they regard the pendulum or regulating part of the motions. The greateſt objection in theory to this conſtruction is, that the additional gravity commences inſtantaneouſly, and alſo ceaſes inſtantaneouſly, and at a part of the vibration where the inſtantaneous exertion of extraneous force of any ſort is the leaſt favourable for aiding the ſimple gravity of the pendulum's ball, which conſideration is analogous to the obſervation we had occaſion to make on Harriſon's eſcapement: but, like his, the eſcapement before us has ſtood the teſt of practical experience, notwithſtanding its complexity, in his majeſty's private obſervatory. If, however, this eſcapement is not *better* than any of the other eſcapements, the number of its adjuſtments, and variety of its parts, conſtitute a practical objection to its general adoption; and we believe no proof has been given of its being preferable to Harriſon's, or even to the common dead-beat or iſochronal eſcapements, except that the works of the clock that has this eſcapement may not require to be ſo often cleaned. This eſcapement leaving the pendulum free or detached from the wheel-work during the greateſt part of each vibration, is of the third claſs of eſcapements.

22. *Eſcapement by Mudge for a clock.*—The clock eſcapement contrived by Mr. Mudge to detach the pendulum from the train, ſo as to allow it to have nearly a free vibration maintained by gravity alone, may be conſidered as a ſimplification of Cumming's eſcapement juſt deſcribed, from which its principal difference is, that each of his two ſeparate pallets act alſo as detents; the mode of action and effect produced are very ſimilar in both. Mr. Mudge's eſcapement is repreſented by *fig.* 7. of our laſt plate, in which L M is a portion of the ſwing wheel; G A and G B are two levers ſeparately moveable round one common axis of motion, and have each a pallet at the lower extremities; theſe pallets are formed like the common recoil pallets, except that each has a claw at the loweſt point, that prevents the eſcape of the ſliding tooth when acting thereon: the pallet G A has a lever,

which may be called its tail-piece G O, attached to it, and alſo a ſmall metallic ball *u* ſurmounted on a pin over the pallet, which may be eaſily changed for one of a different weight; the pallet G B has a ſimilar tail-piece I O, with a ſimilar ball *v* over its pallet B; and the dark circular ſpot at N is the end of a ſtiff pin projecting from the pendulum, or its crutch, far enough to fall in the way of the tail-pieces alternately, as the pendulum vibrates. After having peruſed our account of the action of the preceding eſcapement, the reader will anticipate the explanation we have to offer of this mechaniſm. Suppoſe the wheel to be urged by the train in its proper direction from I towards M, and an impulſe given to the pendulum, to produce a motion in it in a contrary direction; the pin N keeps pace with the pendulum towards L, while the tooth at L is locked in the claw of pallet A, (which it is ſuppoſed to have raiſed ſo as to bring the tail-piece G O out of its vertical direction,) and at length meets with this tail-piece, to which it gives a puſh, at the extremity of the vibration, ſufficiently ſtrong to drive the pallet A from its locked tooth L, when the wheel is at liberty to proceed, till the tooth near pallet B raiſes it and its ſurmounted ball *v* until the claw detains the further motion; in the mean time the returning vibration commences, and the ball *u* urges the pendulum, by means of its tail-piece G O being in contact with the pin N; when, however, the tail-piece has gained its vertical ſituation, the pallet A meeting with the rim of the wheel ſtops; the pendulum now finiſhes its vibration in a detached ſtate, having gained an acceſſion of force by the impulſe from the ball *u* downwards, which has been greater than the reſiſtance it met with in moving upwards at the inſtant of unlocking: the tail-piece I O is now in the ſituation of I P, by reaſon of the ball *v* being elevated by the wheel, therefore when the pin N of the pendulum arrives at I P, which is at the other extremity nearly of the returning vibration, its ſtroke drives the pallet B in its turn from the locked tooth near M, which now eſcapes; the wheel is again at liberty to proceed till the tooth behind L has raiſed the pallet A a ſecond time, when it is again locked; the pendulum begins another vibration, aided by the ball *v*, till its tail-piece reſumes its vertical poſition, and then the pendulum is again detached, after being a ſecond time urged down a longer arc than it was oppoſed up; and thus the vibrations are maintained by the exceſs of the downward puſh over the reſiſtance upwards at every new vibration, which exceſs, derived from gravity alone, is in fact the maintaining power of the pendulum. This eſcapement is alſo of the third claſs, and being more ſimple in its conſtruction than its predeceſſor and parent, perhaps we may add, is better adapted for practice. The external force derived from the gravity of the balls in aid of the pendulum's gravity is here alſo both applied and withdrawn ſuddenly, as well as at the moſt unfavourable parts of the vibration, as was the caſe with Cumming's eſcapement; but it poſſeſſes the ſame advantages of detachment from the train.

23. *Detached eſcapement by Peter le Roy in* 1748.—We have deviated a little from the regular order of time, in having noticed the detached clock-eſcapements before thoſe that were previouſly applied to the balance, in order that the ſucceſſion of improvements made in clock-eſcapements might not be interrupted by an intermixture with watch-eſcapements. We now go back again to the year 1748, when Peter, the eldeſt ſon of Julien le Roy, invented an eſcapement for a balance that vibrated a conſiderable portion of its total arc without any connection whatever with the eſcapement wheel, and which therefore may be conſidered as the father of the third claſs of eſcapements, and the origin of the ſubſequent more recent improvements in the eſcapement of chronometers. *Fig.* 8 *of Plate* XXXIII. will afford us the means of explaining this eſcapement, a model of which was preſented to the Academy of Sciences at Paris in the year 1748, previouſly to which year, no detached eſcapement had been made public, though Du Tertre is ſaid to have invented one, and even to have made it at the time; but as the invention, or at leaſt the conſtruction, was kept a ſecret, it did not derogate from the merit of Peter le Roy's contrivance, which muſt be conſidered as original. G H is the eſcapement wheel of the contrate kind, actuated by a pinion on its arbor, receiving the force of the maintaining power; its profile is ſeen contiguous to it, at *g h*; T V is the balance, the verge of which has a ſpiral ſpring attached to it at the interior end in the uſual way; a curved pallet A E is faſt to the verge under the balance, and the ſemi-circular piece C I is affixed to the ſame above the balance, but under the ſpiral ſpring; the end C of this piece is rounded, and ſo ſituated, that a line drawn from it to the centre of the balance would form with the curve A E an angle of about 80°. An angular lever Q P X, turning on pivots under a little cock on the plate at C, is ſo proportioned, that the branch P Q will reach the pallet, while the other branch P X with a concave end will reach to a tooth G in the balance wheel, when not reſting on a pin K, to which in its quieſcent ſtate it is kept by the ſpring R M, made faſt to the plate on the other ſide at R. Suppoſe now, the regulating ſpring moved from its ſtate of natural reſt, and the balance to move with it through a certain arc of vibration, more or leſs, till the rounded end C of the ſemi-circular piece falls on the branch P Q of the angular lever near Q, and puſhes it from its ſituation, at the ſame time bringing the concave end of branch P X into the way of a tooth G of the wheel; when the acting tooth, which we will call D, eſcapes the pallet A E; the wheel is then at liberty till its tooth G falls on the concave end of the branch P X, which may be called the detent, becauſe it now *detains* the wheel from moving further under exiſting circumſtances. The balance is now perfectly free from all contact of the acting part of the branch P Q, and continues its vibration, after having received a puſh from tooth D on its pallet: preſently its velocity is deſtroyed by the tenſion of the regulating ſpring, the re-action of which now makes it return with an accelerated motion, when the pallet comes into contact with the eſcapement wheel at the tooth following D, which now experiences a recoil for about half of a ſpace in the wheel: the branch P X, or detent, is relieved by this partial recoil, and obeys its ſpring R M, which takes it back again to its ſtate of reſt at the pin K; when the wheel, having ſtopped the balance, ſends it off again with a new impulſe, by ſtriking the pallet in a contrary direction, when the ſame operation of the angular lever is repeated, and the vibrations are maintained as in other eſcapements. It muſt be remarked of this eſcapement, that it does not allow the balance to be detached for an entire vibration, but oppoſes the balance back from the point where it gave its forward puſh, thereby producing a certain recoil, which, ſo far as this is a leading conſideration, would entitle us to rank the eſcapement among thoſe of the firſt claſs, but inaſmuch as the balance vibrates in a detached or free ſtate in the remaining portion of its vibration, we may place this eſcapement with propriety at the head, in point of time of the third claſs.

24. *Peter le Roy's ſecond or improved detached eſcapement.*—Some time after Peter le Roy had completed his firſt detached eſcapement, and had conſidered its principal defects, he ſet about contriving another, leſs liable to objections, in which he ſucceeded in a very conſiderable degree; when in

the year 1766 he preſented a time-piece to the Academy of Sciences, which was afterwards tried at ſea by the French government, with his improved eſcapement, which we ſhall now deſcribe. *Figs.* 1, 2, and 3, of *Plate* XXXIV. exhibit ſufficient of Peter le Roy's improved eſcapement to enable our readers to form a complete idea of its conſtruction; the leading feature of which is to give the balance one temporary puſh that ſhall maintain its motion for two ſucceſſive vibrations, one forwards and the other back, and that this puſh may be given at a moment of the balance's vibration that is moſt favourable for avoiding a derangement of the law of the ſpring's forces. *Fig.* 1. is a view of the balance-wheel, which has ſix radial levers for teeth, but no rim, that it may be as light as poſſible, the ends of which levers are bent downwards, that is, in an oppoſite direction to thoſe on the horizontal wheel with Graham's cylinder eſcapement; the connection of this horizontal balance-wheel with the train is by means of the pinion on the oppoſite end of its arbor; *fig.* 2. is the arbor of the detents, on which there are three levers, one double one for locking, and two ſingle ones for unlocking, all clearly ſhewn in the figure; *fig.* 3. ſhews the wheel, detents, unlocking levers, and balance in their relative ſituations, and in one of the acting poſitions: A is a portion of the balance, on the plane of which is ſcrewed a pallet *p*, ſo as to fall in the way of one of the levers of the balance-wheel. The ſame letters denote the ſame parts in *fig.* 3. as in *figs.* 1 and 2, which therefore explain themſelves. The action may be explained thus: ſuppoſe one of the levers of the balance-wheel to be detained by the claw of the detent D, while the balance put in motion is vibrating in the direction from *i* to A; when the force of the balance ſpring, not ſeen, overcomes the momentum of the balance, it returns by means of the ſpring's force, which is now at its greateſt tenſion, or diſtance from the point of quieſcence; the direction of the balance, we have ſaid, is now from A towards *i*; in this return a pin at *i*, ſituated in the ſuperior plane of the balance, ſtrikes the end of the lever H F of the detent arbor, unlocks by this ſtroke the detent D from the claw of the wheel's radial bar or tooth, and at the ſame inſtant directs the other end H *e* of the double detent into the way of a ſucceeding radial bar of the wheel K *r*, which now reſts on this end of the detent; this part of the action is called by the inventor the *preparation*, the vibration goes on to finiſh, and the ſpring brings the balance back; at a certain part of this vibration the balance receives its ſtroke from the radial bar K, which impels the pallet *p*, ſcrewed on the balance itſelf, in this manner; a pin, ſituated like the former pin at *i*, but placed on the inferior plane of the balance, out of ſight, and a little farther from the balance's centre than the former pin, ſtrikes the end of the ſhort lever H *c*, and unlocks the radial bar of the wheel, that has been reſting againſt the oppoſite end of the detent D, and that now runs on to D, which is in the way to catch it; during this ſhort period the wheel is free, the pallet *p* of the balance being at that inſtant in the ſituation F, the point K of the radial bar K *r* of the wheel purſues the pallet and makes its ſtroke on it, about the time when the balance-ſpring, as we ſuppoſe, is at its quieſcent point, and therefore when the balance is moving with its moſt accelerated velocity; the ſtroke is of ſhort duration on that account, as well as on account of the ſhort diſtance the wheel has to run before it is again detained by the detent D: the backward vibration is made as before, and the ſame proceſs is repeated of two lockings and unlockings at each ſtroke of the wheel on the balance. The ſtroke, however, which the balance receives, has more force than both the ſtrokes that its pins give in the acts of unlocking, and therefore the difference of theſe contrary ſtrokes conſtitutes the real maintaining power of the balance, which was of the thermometrical kind, with alcohol and quickſilver, as deſcribed under our article COMPENSATION-*balance*. The ſtep made towards perfection, when this eſcapement was deviſed, was very long, and the principal objection to it in practice is, that it has too many pivots that require oil, as well other parts that come ſucceſſively in contact during the action, which therefore are not ſufficiently free from friction and conſequent wear. It may be neceſſary to add, that to prevent the detent's being diſplaced by any jerk, a long tail-piece behind it is contiguous to a circular appendage of the balance, ſeen from *i* to F, againſt which it falls, but only when any derangement of the detent accidentally takes place, and thus reinſtates it. The ſtroke is given to the balance not only when its velocity is greateſt and leaſt liable to be deranged, but the pallet that receives it, being removed from the centre of the balance, requires but a comparatively ſmall impulſe in this ſituation; beſides, the ſpring, which the inventor conſidered as not deſirable, for holding the angular lever to its place of locking, is here entirely diſpenſed with. This was conſidered as an improvement at the time, but ſubſequent experience has proved the utility of ſpring detents, which are now in univerſal uſe in the beſt Engliſh chronometers.

25. *Detached eſcapement by F. Berthoud.*—Ferdinand Berthoud, one of the members of the National Inſtitute of France, and the author of various works on horology, has contrived different eſcapements for clocks and watches at different times, and has written more on the ſubject than any other author, but it will not come within our plan to detail here all the alterations that have preſented themſelves to him; we ſhall ſatisfy ourſelves with deſcribing a few of thoſe which he has himſelf ſelected as moſt worthy of public notice in his laſt publication; "Hiſtoire de la Meſure du Temps." Others may be ſeen in his "Traité des Horloges Marines;" or in the "Supplement" to that work. The firſt that we mean to deſcribe is contained in *fig.* 4. of *Plate* XXXIV., which is a perſpective view of all the parts neceſſary to be ſeen: A repreſents the verge of the balance, to which is affixed by two ſcrews the circle of eſcapement B as a pallet; C is the eſcapement wheel, *a b c* the detent, which has at *b* a claw to catch a tooth of the wheel, when it ſuſpends its motion, during the period of the balance's free vibration; the portion *a b* of the detent is a flexible ſpring, that yields firſt at the point *a*; this, therefore, is the *ſpring of the detent*; the other part *b c* properly forms the detent, which has a claw rounded at the end *c*; another ſlender ſpring *b e* lies croſs-wiſe near the ſaid end, and is held faſt to the circle B by a ſcrew and fixing-piece *f*; this ſecond ſpring carries a pin *d* near its extreme end, which acting on the end of the detent, diſengages the locked tooth of the wheel, when the balance vibrates in a direction from B towards A; at that inſtant the ſucceeding tooth of the wheel acts on the notch or pallet part of the circular piece B at *h*, and tranſmits an acceſſion of force to the balance, which now vibrates in free ſpace; at the balance's return, the pin *d* of the ſmall ſpring *d e*, borne by the balance's circular piece B, applies itſelf to the end of the detent, ſo as to ſlide paſt it without diſturbing its poſition with regard to the claw, againſt which the next tooth is now reſting; when the balance has finiſhed this ſecond vibration it returns, the pin *d* again puſhes aſide the detent, and unlocks the wheel, which now gives another puſh at *h*, and the ſame operation is reſumed that we have been deſcribing. Thus two vibrations are performed at once unlocking, and at one ſtroke of the wheel on the notch of the circular pallet piece. The ſmall ſpring *b e* may

be called the lifting ſpring, in oppoſition to the detent ſpring, or ſpring detent; and to give a clear idea how it detaches the claw of the detent in paſſing forwards, but not in paſſing back again, it may be neceſſary to obſerve, that this lifting-ſpring has a pin in the circular piece B, againſt which it reſts, to prevent its laying too much hold on the back ſloping part of the detent's extremity; but it is at liberty to yield in the contrary direction towards the verge of the balance; and as the ſpring is very ſlender, and has its yielding point or centre of motion at the remote end *e*, it gives way to the detent in the direction that puſhes the detent againſt the tooth of the wheel, which becomes a prop to ſteady it; but when the impulſe is in a contrary direction, the detent, having no ſuch prop, and its end being at that ſide ſuited to receive the blow of the pin without its ſliding, itſelf yields and withdraws its claw from the wheel, which is then unlocked. The ſpring of the detent is alſo confined from rebounding too far by a pin *g* fixed in the plate. Here we have an inſtance of a retrograde ſtep in the improvement of eſcapements, the ſpring which Peter le Roy laboured to reject in his ſecond conſtruction is here reſumed with an additional ſpring, and the adoption of the *ſpring-detent* has become general in the ſubſequent conſtructions. Berthoud began his detached eſcapements in the year 1754.

26. *Another modification of a detached eſcapement by Berthoud.*—The eſcapement which Berthoud employed in ſome of his watches, particularly N° 60, was conſidered by him to be more ſure in its action than the preceding one, as well as more eaſy of conſtruction; *fig.* 5. of the ſame plate repreſents the plan of one of theſe eſcapements, where L is the eſcapement wheel; *m* the circle of eſcapement carried on the verge of the balance; *p o r* the detent, the claw of which at *r* ſuſpends the motion of the wheel; the verge carries above the circle *m* a ſmall tube made faſt by friction, and to this tube is made faſt a projecting forked claw, in which a pin is adjuſted to act on the detent and raiſe it. The pin, which we will call *s*, in turning in one direction, acts on the part *p* of the detent, and withdraws the claw *r* from the wheel; this is now at liberty to impel the circle *m* by its notch and with it the balance; the ſlender ſpring *u* brings back the claw of the detent, and the vibration goes on; at its return the pin meets with the end of the detent-ſpring fixed on an arm at *t*, this ſpring yields to the retrograde motion of the balance. The balance at its return makes its pin (of the fork) urge the ſpring *p* againſt a pin *s* in the arm *n* of the detent; this arm turning on its centre of motion, withdraws the claw of the detent from the wheel, which now acts again on the notch of the circle *m*, as before. The pin *q* ſerves as a ſtop to the detent, and the arm *k* of *precaution* is to lock the wheel when the balance is diſmounted.

27. *Another eſcapement without a ſpring by Berthoud.*—*Fig.* 6. of the laſt plate is a view of an eſcapement by Berthoud, in which he has diſpenſed with ſprings altogether. The action of the wheel A is tranſmitted to the balance, as before, by the notch of the circular piece B on the verge; the preſent poſition of the parts is for the moment when the detent allows the wheel to begin its action on the notch of B. The detent C has two arms, with each a claw *a* and *b*, the faces of which are circular; the claw *a* ſerves to ſuſpend the action of the wheel after its ſtroke is made; but the claw *b* receives the tooth of the wheel when the balance in its return makes the tooth at *a* to eſcape. Theſe effects are produced by two levers C *d*, C *e*, forming the fork that moves the detent C: this fork is fixed on the centre C of the detent, and its levers lie one above the other. The lever C *d*, which is contiguous to the detent, correſponds to the ſmall ſemi-circular piece *d e*, placed on the circle of eſcapement B; this ſemi-circle is notched by lines, one of which tends to the centre; this ſide of the notch unlocks the wheel by its action on the arm C *d* whenever the balance retrogrades from the firſt vibration of the pair; during this effect the wheel advances but a ſhort way, juſt ſufficient to unlock the claw *a*, and to ſuffer the balance to proceed in its retrogradation. The balance, having finiſhed in a detached ſtate this ſecond vibration, returns, when the ſemicircle *f g*, placed over the other ſemi-circle, and notched in like manner, preſents its acting ſide to the upper arm *f* C of the fork, and unlocks the tooth at claw *b*; at this moment another tooth, catching the notch at *c* of the circular piece B, gives it another impulſe, and conſequently puts the balance in a ſtate of renewed force, and the proceſs already deſcribed is renewed, while the ſemi-circular pieces *d e* and *f g* on the verge alternately ſerve to keep the arms C *d* and C *e* of the fork in a firm poſition to enſure the deſired effects of the eſcapement. It is eaſy to perceive that there muſt be much friction in this eſcapement, and that the ſemicircular pieces on the verge of the balance, if not ſomehow counterpoiſed, muſt affect the rate of going in different poſitions of the time-piece.

28. *Detached eſcapement with a detent and ſpring by Berthoud.*—*Fig.* 7. of the ſame plate is the plan of another of Berthoud's eſcapements with a detent and ſpring, and that which we underſtand has been moſt copied by others. It was uſed in the author's marine time-piece N° 9. A is the circle of eſcapement; C the wheel; *a b d* the detent with three arms; the arm *a* ſuſpends the motion of the wheel while the balance oſcillates in a free ſtate; the ſpring *d* ſerves to bring the detent *a* back again as ſoon as the pallet *c* has ceaſed to act on the arm *b*; at that moment one of the teeth of the wheel impels the circle by acting on the roller *h*, and communicates its force to the balance; this having finiſhed its oſcillation returns, and in the return the pallet *c* meets with the end *b* of the detent, which turns the pallet back towards B, the centre of the circle, till it has paſſed without unlocking the wheel; its ſpring *b* brings the pallet back again to its original ſtate of reſt on the pin at *c*, the oſcillation ceaſes, and in the return of the balance the pallet *c* again meets with the arm *b* of the detent, which it turns aſide, the tooth being no prop to it in this direction; the unlocking therefore takes place; the wheel's motion is reſumed, and a new impulſe is given to the moving balance. Here the detents are arms or levers acted on by a ſeparate ſpring, as is alſo the pallet, conſequently there ſtill remain pivots that require oil, though we are diſpoſed to conſider this as the beſt of Berthoud's watch eſcapements; perhaps equal to any of the Engliſh conſtructions.

29. *Iſochronal eſcapement of a watch by F. Berthoud.*—Among the other contrivances of Berthoud is an eſcapement for a watch with iſochronal pallets, ſimilar to thoſe applied to a pendulum which we have deſcribed above, but the mode of applying them is different. In *fig.* 8. of our laſt plate, A is the eſcapement wheel; B the anchor with the iſochronal pallets producing a ſmall recoil, and formed in the manner before deſcribed, (ſee *fig.* 1. of *Plate* XXXIII.) C D the balance; *a* a pinion on the verge above the wheel, that is actuated by a ſectoral toothed piece *b*, attached to the anchor of the pallets, and moving with it round the common centre of motion of it and the pallets at E; the intention of this conſtruction is to produce a long oſcillation of the balance compared to the motion of the wheel and toothed ſectoral piece, and to render all the oſcillations, however long or ſhort, of equal duration, the arcs of action being large in proportion to the whole oſcillations. This conſtruction

may have given riſe to that which is now known by the name of the Liverpool eſcapement, which ſo greatly reſembles it, that they may be conſidered as the ſame thing. We obtained a watch by Litherland of Liverpool, with a view of giving a ſeparate deſcription and drawing, but we found that the only difference is, that the pallets are placed a little on one ſide of the wheel, inſtead of the three pivots being in one ſtraight line, and that the centre of the pallet's motion is between the verge and pallets requiring a counterpoiſe behind: a further deſcription is therefore unneceſſary.

30. *Modern eſcapements of Engliſh chronometers.*—If we had not already anticipated our deſcriptions of the modern eſcapements for chronometers, as they are now made in England, we ſhould have given them a place here; but as we have been very minute in our account of the eſcapements of Meſſrs. Mudge, Arnold, the Brockbanks, and Earnſhaw, under our article CHRONOMETER, and have given drawings of them in our *Plates* XIII. XIV. and XV., it would be ſuperfluous to enter into a ſecond detail of the ſame here, and therefore we paſs over them by a ſimple reference to the article already named.

It may not be improper to mention here, that Mr. John Watkin, of Weſt Smithfield, has propoſed an alteration in the ſituation of the pallets in the modern ſpring-detent eſcapement, for which he received thirty guineas as a premium from the Adelphi Society, in the year 1804. His alteration conſiſts in bringing the pallets into a ſituation between the centre and circumference of the wheel, and making the wheel a contrate one with the teeth upwards. (See the Tranſactions of the Society, vol. xxiii. p. 375.)

31. *Mudge's forked eſcapement.*—Mr. Mudge contrived another detached eſcapement beſides the one we have referred to as already deſcribed, which we ſhall now notice, though he did not ſeem to place ſo much value on it as Emery, Margetts, and others have done after him; we ſhall not be able to make the reader comprehend the conſtruction without two figures: *fig.* 1. of *Plate* XXXV. is the plan of this eſcapement, and *fig.* 2. a profile or ſide view of the frame that contains the mechaniſm: A is the eſcapement wheel, B the anchor of the pallets, which are of Graham's dead-beat kind adapted to a watch, and which give the neceſſary force to the balance for maintaining its motion; *a* is the centre of motion of the anchor, nearer to the wheel than to the balance; *b* is the forked part of the anchor, the two prongs of which appear in *fig.* 1. to be cloſe together in the ſame plane, but *fig.* 2. ſhews that they are one above the other. The pallets are on the verge of the balance, and are of the cylindrical ſort, one above the other, ſo as to fall in the way of the two prongs alternately, pallet 1 is urged by *b*, and pallet 2 by the other prong in its turn; the time of action of the prongs on the two pallets is very ſhort, and the blows are made alternately one in each vibration; the remainder of the vibration is perfectly free, the wheel being in the intervals reſting on the circular portions or pads of the anchor's pallets, which may in this caſe be conſidered as detents and pallets alternately. A timepiece by Emery with this eſcapement performed with wonderful accuracy, though the detachment continues only for a portion of one vibration before the balance has its force renewed, which conſequently might be ſuppoſed to have its motion more diſturbed than if the impulſe had been given at each alternate vibration. The queen's watch by Mudge with this eſcapement had a ſlight recoil, which kept one of the prongs preſſing gently againſt the cylinder of the verge to ſteady the fork. The performance was excellent.

32. *Margetts' modification of Mudge's forked eſcapement.*—The late ingenious Margetts adopted Mr. Mudge's eſcapement, which we have juſt deſcribed, for his chronometers that indicated both ſolar and ſiderial time, but made ſome alterations with the fork. *Fig.* 3. of the ſame plate ſhews the plan and profile of Margetts' modification, where A is the wheel; *a b* the anchor moveable at *a*; *b* the fork where the prongs are in the ſame plane; *c* a piece of ſteel carrying a pin *e* under its extreme end that ſtrikes the prongs of the fork *b* alternately, one at each oſcillation of the balance *g*, which ſtrokes unlock the wheel; *h* and *i* are two banking ſcrews, the points of which act as ſtops to the anchor at oppoſite ſides of the centre of motion, and keep the fork in its place to be caught by the pin *e*, one or other of them at each vibration; *d* is a circular piece of metal, under the pallet piece *c*, that has a notch in it bounded by ſtraight lines going towards its centre; and *f* is a pin carried under the anchor, as ſeen in the figure, the end of which gives the circular piece *d* a puſh, by acting on its notched ſide at each unlocking of the wheel, thereby aiding the vibration: the pin *f* is always at the notch when the pin *e* is in the fork, therefore the notch in *d* and the pin in *c* are always placed in the ſame vertical line over one another, and as they move together on the verge will always remain ſo, while the pin *f* and fork *b* are alſo together on the anchor. The writer of the preſent article has a chronometer by Margetts with this eſcapement, which acts very well when ſtationary, but when carried in the pocket the pin is apt to catch the outſide of the prong, when any jerk has ſent the anchor back during the balance's excurſion.

33. *Modification of Mudge's forked eſcapement by R. Robin of Paris.*—R. Robin, a watch-maker of Paris, publiſhed a memoir in 1794, containing an account of a free eſcapement, which he conſidered as new, but which we conſider as another modification of Mr. Mudge's forked eſcapement, though we allow that in theory it appears to be an improvement. *Fig.* 4. of the ſame plate is a plan of this eſcapement, in which the wheel reſtores the exhauſted force of the balance once only in two vibrations, which circumſtance conſtitutes the improvement; to effect this, pallets G *a*, and G *b*, acting as detents, are made of unequal length from G, the centre of their motion, and the fork, which is ſeen ſeparately at *e*, as well as the tooth or pallet *d* and lever *f*, are concealed under B, the circular piece carried by the balance; the fork *e* is faſt to the end of one of the pallets *a*, inſtead of forming an anchor with the pallets, but this ſhape makes no difference in the action; the lever *f* is alſo faſt to the ſame underneath the fork; but the tooth *d*, which acts with the fork, is faſt to the verge under B, as we have already ſaid. We have given three poſitions of the circular part B and pallets, to ſhew more clearly the nature of the action, as ſome of the acting parts are concealed. One of the claws *a* of the pallets being removed, the wheel A eſcapes, and acts on the notch of the piece B, thereby aiding the balance; the claw *b* receives another tooth and holds it as a detent, and the balance finiſhes its oſcillation; at its return it unlocks the tooth at *b*, which is the longer pallet, and the wheel runs on a very ſhort way till a leading tooth falls on the pallet *a*, and the balance vibrates without a new puſh; at its return the tooth at *a* is unlocked, and its eſcaping tooth gives the notch of B another puſh, which ſerves for other two vibrations; but if the two ends of the pallets G *b*, and G *a*, had been of equal lengths, the eſcapement would have acted in the uſual way, and would have given its puſh at each oſcillation. The manner in which this effect is produced, however, does not yet appear evident; the lever *f*, which is faſt to the end *a* of the pallet or detent G *a*, reſts in a groove made in a circular collet on the verge, and holds the fork *e* from going on one ſide, like as the banking

ſcrews do in Margetts' eſcapement, then the tooth *d*, faſt to the balance, ſtrikes the two prongs of the forks alternately, one at each vibration, which ſtrokes make two unlockings during the time that one puſh is made to the balance by a tooth; becauſe the ſaid tooth previouſly made two ſteps forward, one long and one ſhort, before it eſcaped to make its puſh. We have not been informed how this modification performed, but we ſee no reaſon to doubt its competency, while we ſee much reaſon to admire the ingenuity of the application of two detents of unequal length, formed like the pallets of the anchor eſcapement, which detents we have named pallets on that account.

34. *Prior's modification of Mudge's forked eſcapement.*—In the year 1798 Mr. John Prior received 30 guineas as a premium from the Society for the Encouragement of Arts at the Adelphi, for his invention of what he conſidered a new detached eſcapement; but its fork differs from Mudge's principally in its having a roller for a pallet borne by an arbor carried by the balance itſelf; the wheel of eſcapement, together with its acting pallets, were ſimilar to Le Paute's improvement on Amant's wheel, and therefore had nothing original in it. The reader who wiſhes to ſee the account and drawings of this eſcapement, compoſed as it is of Mudge's and Le Paute's contrivances, which notwithſtanding the author might not have ſeen or known, may find it in the 16th vol. of the Tranſactions of the Society juſt named, and alſo in the 2d vol. of Nicholſon's Journal, 4to. ed. p. 363 and 364, where the editor has remarked that Mr. Croſthwaite of Dublin had made a pendulum clock with ſimilar pallets in 1788, which was deſcribed in the Memoirs of the Iriſh Acad. vol. ii.

Prior junior has very recently been rewarded by the ſame ſociety for another eſcapement contrived by him for a clock, but the account of it is not yet publiſhed in their Tranſactions, and therefore cannot with propriety be given here.

35. *Duplex eſcapement.*—We are not informed who was the original contriver of the eſcapement known by the name of *Duplex* eſcapement, a name probably taken from the circumſtance of its having a wheel with *two* ſets of teeth neceſſary for the eſcaping; neither are we aware of its date; but the eſteem in which it is held by thoſe who have tried it, entitle it to a place in our collection. *Fig.* 5. of *Plate* XXXV. exhibits on a large ſcale enough of the acting parts to enable us to convey an idea of its action. A B is a part of the eſcapement wheel, having teeth *a*, *b*, *c*, &c. at the periphery, intended for detaining the wheel while it oſcillates beyond the angle of action. An agate cylinder *d e f*, placed on the verge of the balance, acts with theſe teeth to produce the deſired effect. This cylindrical agate has a notch *d*, which paſſes by the tooth at D, that is ſuppoſed to reſt on the cylindrical ſurface, when the motion is in the direction *d e f*; but when the motion of the cylinder is in the contrary direction *f e d*, the tooth at D falls into the notch and accompanies it, preſſing on one of its ſides till the notch comes into the ſituation *d*: the tooth, then at the ſituation of *b*, eſcapes from the notch, and a ſucceeding tooth falls on the convex ſurface of the cylinder at D. The other ſet of teeth are erect on the plane of the wheel's rim, and are ſtrong and ſquared at the ſides; they ſtand a little ſhort of the middle of the ſpaces between the pointed teeth on the edge of the wheel, but conſiſt of the ſame number; they are to be ſeen at *h*, *i*, &c. denoted by darkened parallelograms: above the ſmall cylinder we have named as being made of agate, is a larger one E F G without a notch, and placed high enough on the verge to go over the edge of the wheel's rim; this bears a pallet of ruby or ſapphire G, long enough to fall in the way of the ſquare vertical teeth, when they happen to be near the line joining the centres of motion of the balance and wheel, but ſhort enough to avoid touching the teeth when not near that line. The larger cylinder is ſo placed with reſpect to the ſmall one, that when the tooth *b* has juſt eſcaped from the notch, the pallet G has juſt paſſed the ſquare tooth *h*, which was at A, while D reſted on the ſmall cylinder, but is moved from A to *h*, while D moves to *b*. The wheel is now free, and the tooth *h* exerts its force, derived from the main-ſpring, in the moſt direct way on the pallet G, and urges it forward till another tooth on the edge falls on the convex part of the ſmall cylinder *d e f*, and the ſame action that has been deſcribed is reſumed. The angle of action in this eſcapement depends partly on the length of the pallet G, and partly on the diameter of the ſmall agate cylinder, and advance of tooth D into the notch; for when a horizontal tooth on the edge falls on the ſaid ſmall cylinder, the motion of the wheel is arreſted, and the vertical ſquare tooth ceaſes to impel the pallet G ſo far as it otherwiſe would have done. This eſcapement requires very little oil on the ſmall agate cylinder, and none at all on the pallet G, which receives a direct puſh without friction, and its excellence is conſidered as at leaſt equal to that of Graham's horizontal or cylindrical eſcapement.

36. *Free eſcapement under the pendulum.*—The clock eſcapements which we have before deſcribed ſuppoſe a connection with the upper end of the pendulum, which is the moſt common connection, but there are eſcapements that give their impulſe at the inferior end, one of which is repreſented by *fig.* 8. of *Plate* XXXV. which we ſhall now deſcribe, though we know not who was its original contriver. The part A B D C is made faſt to the rod of the pendulum, and vibrates therewith; at B is a joint on which the lever B C is moveable; ſo that when the end C meets with any reſiſtance the lever mounts upwards at this end, but cannot fall below a horizontal line; it terminates in a claw with both an interior and exterior ſlope or inclined plane; D is a pallet of agate or other poliſhed ſtone, with a flat face next the end C of the lever, and made faſt into the vertical part A D; F G H I is a two-armed detent, moveable round H as a centre, but kept in its preſent poſition againſt the ſtop or pin K, by means of the weight G, when not otherwiſe acted on. In the preſent poſition the arm H I, which forms the detent, detains the tooth I of a vertical wheel of eſcapement, while the pendulum is ſuppoſed to be vibrating clear of all the teeth. Let us ſuppoſe the end C of the horizontal lever, moving with the pendulum, to be approaching the end F of the ſecond arm of the detent; preſently it gives the end F a blow, the lever C flies up, ſlides over the inclined face of F, and returns into its horizontal poſition; when the vibration terminates, the pendulum returns by virtue of its gravity, and the interior face of claw C catches the exterior one of the arm F, and gives it a pull ſufficient to draw the end of H I from the tooth I; the wheel is then at liberty to run on till the tooth E, moving faſter than the pendulum, overtakes the pallet D, and gives it a direct puſh forwards; this puſh aids the claw C to get over the claw of F, and the weight G replaces the arm H I to catch the following tooth M, which prevents the further impulſe of the wheel on the pallet D, and ſuffers the pendulum to finiſh its vibration in free ſpace; at the return of the pendulum the ſame operation is repeated, and the pendulum continues to receive one puſh at every two vibrations, and that when the pendulum is in its vertical poſition, or moving with its greateſt velocity, which we have ſaid is the moſt favourable point of the arc. The arc of action, before the pallet is quitted, depends greatly on

the radius of the wheel compared to the length of the pendulum, when the number of teeth is limited. The pendulum, however, ought to be of the compenſating kind, otherwiſe an increaſe in the length of the rod will derange the action of the claw C, with the claw F, as well as of the tooth on the pallet D, in all the extremes of atmoſpheric temperature. The maintaining power of the train that actuates the wheel E M may be either a ſpring or weight, as the mechaniſt may think proper. Berthoud has propoſed this conſtruction of a free eſcapement for a half-ſecond's pendulum in his " Hiſtoire de la Meſure du Temps," tome i. p. 214; but he does not clearly ſay that it was of his own contrivance; on examining his drawings, ſince our obſervations were written on this eſcapement, we find that this author propoſed a compenſation pendulum to be uſed with it; and he propoſes ſuch a combination of parts as a proper model for an aſtronomical clock to vibrate half-ſeconds. Mr. Nicholſon, who has alſo deſcribed the ſame eſcapement as one he has noticed in England, does not venture to aſcribe its invention to any particular artiſt.

37. *Detached eſcapement of a clock by Berthoud.*—Among the numerous contrivances of F. Berthoud in clock-work, we frequently find this author applying the ſame contrivance to anſwer different purpoſes; for inſtance, when he had hit upon an iſochronal eſcapement for a clock, he adapted it ſoon after, as we have ſeen, to a watch; and in the inſtance before us, he has converted a free or detached eſcapement of a watch into a clock eſcapement, which we ſhall here deſcribe, not knowing the exact date of the application. *Fig.* 1. of *Plate* XXXVI. is a repreſentation of an eſcapement of the third claſs adapted to a half ſecond's pendulum, as deſcribed by Berthoud himſelf. F is the eſcapement wheel, and *a*, *b*, the detents of eſcapement, (formed like the pallets of the dead-beat eſcapement of Graham,) the action of the wheel F is tranſmitted to the pendulum by means of the notch made in the circular portion of the eſcapement piece A B, thus; the detent has two claws, *a* and *b*, formed by portions of a circle, at the holding parts. The claw *a* ſerves to ſuſpend the action of the wheel, when it has communicated its motion to the notch of the eſcapement piece, which this does again to the pendulum, by means of the lever C, which it carries, and of the roller D, correſponding to the pendulum. The claw *b* ſerves to receive, and to detain the wheel, when the pendulum returns. Theſe effects are produced by two levers *d c*, *e c*, fixed on the centre *c* of the detent; but one of them more diſtant from the plane than the other. Theſe two levers form a fork that correſponds to the circle of eſcapement *b g*. The lever *d e*, which is neareſt to the detent, anſwers to one portion of the circle *g*, carried by the circle of the eſcapement D. This part *g* preſents a ſtraight line to the fork *d*, which being acted on, detaches the claw *a* of the detent, and, conſequently, ſets the wheel at liberty. The notch *f* preſents itſelf, and the tooth of the wheel acts on the notch, and reſtores to the pendulum the force that it had loſt. The wheel having finiſhed its action on the notch *f*, a tooth preſents itſelf to the claw *b*, and the pendulum finiſhes its vibration in a free manner, at its return, the portion of the circle *g*, which is moſt elevated, meets with the arm *e* of the fork, and diſengages the claw *d*; the tooth that was here detained now eſcapes, and runs on a ſhort ſpace before another tooth drops on the claw *a*, and the proceſs is repeated. We have not ſeen this eſcapement in England.

38. *Eſcapement by Mr. Nicholſon.*—Some time in the year 1784, Mr. Nicholſon ſays (Phil. Jour. vol. ii. 4to. p. 59.) that he contrived a clock eſcapement to go without oil, and which is of the dead-beat kind; it was conſtructed in the year 1798, and when the account was written had been going freely for a year or more. His account is this, *fig.* 2. of *Plate* XXXVI. "is a ſketch, in which G H repreſents a ſteel wheel; D and E are pallets of agate, with flat poliſhed faces. The pallet D is fixed to the lever D C, which is confined to its preſent ſituation by the loaded branch or arm C B reſting on the ſtop *k*. The lever E C is alſo kept in its ſituation by the loaded arm C A reſting upon I. A pin N proceeds from the pendulum rod to its ſituation between the levers. The centre of motion of the pendulum is in the continuation of the axis of the pallets. Suppoſe the vibrations to be begun; the pin N in its progreſs will lift the pallet D towards L, while part of the weight B will be ſupported by the tooth of the wheel which will follow, and at laſt eſcape and ſuffer the oppoſite tooth F to fall on the pallet E. But in its return, or deſcent, the pendulum will be acted on by the whole weight B, and, conſequently, its vibration will be kept up. When the pin N raiſes the pallet E, a ſimilar effect will take place on the ſide of the perpendicular towards M, and thus the proceſs will go on as long as the wheel G H retains any force." In this eſcapement, the two weights are not raiſed entirely by the action of the wheel, but are chiefly lifted by the pendulum itſelf; therefore though the vibration is made during the repoſe of the wheel, in a ſtate detached from the train, yet the pendulum is not detached from the weights, and, conſequently, the compound law of forces by which the pendulum is maintained conſiſts of the action of the pendulum's gravity, of the action of the ball's gravity, which acts in concert with the other, and of a ſhort action of the wheel on the agate pallet; this compound action differs from Mudge's and Cumming's in this reſpect, that their weights are raiſed by the wheel entirely without oppoſing the pendulum, otherwiſe than by the ſhort ſtroke made at unlocking.

39. *Crank eſcapement by Simon Goodrich.*—In the year 1799 the Adelphi Society rewarded Mr. Goodrich for his contrivance of a crank eſcapement, which is exhibited in *figs.* 3. and 4. of *Plate* XXXVI. of which *fig.* 3. is a front view, and *fig.* 4. a ſide view of the ſame, where the ſame letters of reference apply to both. A A A A is the back plate of a clock frame; B the crank fixed to the end of C the arbor of the laſt pinion of the train; D, D, are two ſmall wire chains, compoſed of two links only attached to the crank B, by means of two collets, with great liberty of play. Theſe chains are faſtened to E, E, two ſmall ſprings ſcrewed to F F F, a bar that goes acroſs, and is faſtened in the middle to G G, the crutch of the pendulum. I, I, are two ſcrews going through the bar F; the ends of which being made to act againſt the ſprings E, E, ſerve to adjuſt them to a proper diſtance and degree of ſtrength, and by that means eaſily to put the pendulum into proper beat. In *fig.* 3. the pendulum is partly repreſented by dotted lines, in order to ſhew the crank, &c. The advantages attributed to this conſtruction are, ſimplicity of conſtruction and conſequent cheapneſs; total ſilence during the eſcape; uniformity of action on the pendulum; durability and certainty of continuance; and the power of acting without oil. Theſe properties may recommend the eſcapement before us, but as its influence on the pendulum is conſtant, it is but ill calculated to counteract any irregularities in the maintaining power as tranſmitted and varied by the train under different circumſtances of wear, dirt, and friction. The originality of the contrivance is that of a rotatory motion converted into a vibratory one, which Soumille had done very nearly in the ſame way in the year 1746. (See Machines et Inventions approuvées par l'Academie Royal des Sciences; tome xiii. p. 325.) As there is no eſcapement wheel, a

further explanation is unneceſſary to every one who has ſeen a treadle in action; but it may be neceſſary to remark that an additional wheel and pinion muſt be requiſite in the train where the laſt pinion revolves more frequently than in other eſcapements.

40. *Eſcapement without a verge on the pallets by Ed. Maſſey.*—Mr. Maſſey's eſcapement without a verge was one of two eſcapements which together gained him twenty guineas from the Adelphi Society in 1803; the other, being of the 4th claſs, will be deſcribed in another place. *Fig.* 5. of *Plate* XXXVI. is a plan of this eſcapement, which is of a novel conſtruction, borrowed probably from the ſpring detent eſcapement of the modern chronometers, and adapted to a clock, where the pendulum is free, during a large portion of its vibration. The pendulum rod is ſeen at *a*, ſuſpended by a piece of watch ſpring in the uſual way, but without a crutch and verge; *b* is the ſwing wheel with its teeth ſhaped like the dead-beat kind, except that they are rounded at the end; this wheel is not within the frame as uſual, but on the outſide of the back plate; *c* and *d* are the arms of the pallets *f* and *g* reſpectively; theſe arms are attached to the frame, and are adjuſtable for the included angle by the ſcrews *h* and *i*, which preſs againſt the upper ends of the arms, that open like a pair of tongs, and are kept open by a ſlender ſpring *e* forced into notches at the ends. A croſs bar *k*, carried by the pendulum, gives alternate ſtrokes to the two pins fixed in the pallets *f* and *g*, at the time of unlocking. In the figure the pendulum is ſuppoſed to be in motion with the pin of pallet *g* reſting againſt the croſs bar *k*, which bar it impels on the returning vibration, and aids the pendulum, while the inclined plane of pallet *f* is raiſed by the wheel to give its ſtroke, when unlocked, in a contrary direction. Thus the pallets are raiſed partly by the wheel and partly by the pendulum, as is the caſe with Mr. Nicholſon's pallets; for the ſpring in this caſe performs the ſame office that the weight does in that; but in this eſcapement the inclined planes muſt require oil, which is not neceſſary in the other, where the wheel acts by a direct puſh without any ſliding motion. The inventor tells us, that a more than uſually large maintaining power is neceſſary when this eſcapement is adopted, which indeed muſt be the caſe with all detached eſcapements, where the duration of the impulſe is ſhort.

The reader may have obſerved that we have not yet noticed in this article the fourth claſs of eſcapements which act by the aid of *remontoirs*; this omiſſion has been intentional, not only for the purpoſe of avoiding the further enlargement of the article, but that we may give the hiſtory of the invention of the *remontoir*, and of its modifications by the different ingenious men, who have preferred its uſe to that of a detached eſcapement without ſuch additional aid. We have already had occaſion to ſpeak of Harriſon's and Mudge's auxiliary ſprings, or remontoirs, under our article CHRONOMETER, and it will ſuffice, for our preſent purpoſe, to name here that Huygens, Leibnitz, Gaudron, Haley, Breguet, De Lafons, Maſſey, Mendam, Antis, and others have taken a part in bringing the remontoir into notice, as we ſhall have occaſion to relate more particularly under the article REMONTOIR.

ESCARAY, in *Geography*, a town of Spain, in Old Caſtile; 5 miles S. of Calzada.

ESCARIGO, a town of Portugal, in the province of Beira; 12 miles N.W. of Penna Macor.

ESCARPE, or SCARP, in *Military Affairs*, relates to the exterior ſlope of each defence, while on the other hand the interior ſlope of every excavation beyond or facing the eſcarpe is deſignated the counter-ſcarp. It may be neceſſary to remark, that, in ſtrictneſs, the term is not applicable, except where ſome talus or ſlope is given to the exterior, though it is in very general and indiſcriminate uſe. Originally, when the ſides of hills, &c. were to be defended, it was found neceſſary to remove all ſuch maſſes as might afford cover to an approaching enemy, or enable them to aſcend to the aſſault; each rugged exuberance being in ſuch caſes adequate to the ſteps of a ladder, and offering a footing to the aſſailants.

To avoid this facility of attack, it became cuſtomary to chip away the prominent parts, and to render the ſurface inacceſſible; this was effected by eſcarping it, (from the French verb *eſcarper*, to cut ſteep or ſloping,) in ſuch manner as to render it impoſſible for any one to aſcend without the aid of ladders, &c.; giving at the ſame time a direct line of fire to the defenders, and enabling them to roll down ſtones, &c. with prodigious effect, upon ſuch as ſhould have the temerity to aſſault.

Latterly, however, the term has been applied to the exterior face of the works, whether the wall, or revetement, be inclined or perpendicular. Nor does the corruption ſtop here; for many are in the habit of calling the berm the eſcarpe, and of confounding the covert-way with the counter-ſcarp: whereas neither the eſcarpe nor the counter-ſcarp have any thing to do with the terre-pleine, or level ground; but are applicable ſolely to the inclined faces of the ditch and ramparts reſpectively.

It is true that modern engineers, who often allow their phraſeology to follow cuſtom rather than etymology, make little, if any, diſtinction between ſuch revetements as are inclined, and ſuch as are perpendicular: not that many opportunities exiſt for indulgence in this error; there being very few walls or revetements intended for military works, and eſpecially for the faces of parts ſubject to be battered, which have not a talus equal to at leaſt one-ſixth of their reſpective heights.

In ſome fortreſſes leſs reliance is placed on the artillery mounted upon the ſeveral works than upon the advantages afforded by the inclination of the eſcarpe. Thus, where a fort or redoubt is built upon a conical mound of rock, of which the interior may be excavated for lodging the defenders and their ſupplies, if the face of the cone be every where eſcarped to an angle of about 40°, or more, from the horizon, a very moderate perpendicular, ſay to the depth of ſeven feet, around the ſummit, will prevent any aſſailants, however numerous, from carrying the place by ſtorm; provided that perpendicular be properly manned and ſupplied with large ſtones, perhaps from twenty to a hundred pounds weight, which being rolled down the eſcarpe, invariably precipitate all who may be in the line of their deſcent; ſuch a defence is not to be overcome ſo long as vigilance is maintained, and a ſupply of ſtones is at hand.

In India, (as well as in other parts of the world,) ſmall forts are often eſcarped on this principle; there the ſtones held in preparation for defence, all along the interior of the parapet, are deſignated "Mut-wallahs," (*i. e.* drunken men,) in alluſion to the manner in which they roll, and in which thoſe whom they overſet are tumbled down to the plain below.

ESCARS, in *Geography*, a ſmall town of France, in the department of the Upper Vienne; 15 miles S.W. of Limoges, which, before the French revolution of 1789, conferred the title of count on the lords of the manor.

ESCARTELE', in *Heraldry*, quartered, or quarterly. See QUARTERING.

ESCATALENS, in *Geography*, a ſmall town of France, in the department of the Lot; 6 miles W. of Montauban.

ESCATARI, a ſmall iſland about 5 leagues N. of Louiſbourg, in the iſland of Cape Breton.

ESCATRON, a ſmall town of Spain, in the province of Aragon, above the conſluence of the Martin and Ebro, nearly oppoſite to Rueda, between Saragoſſa and Mequinenza.

ESCAUT, The, more generally known in England by its Flemiſh or Dutch appellation of the *Scheldt*, or *Schelde*, was formerly a river of Auſtrian Flanders, and is now a river of France, which gives its name to one of the northern departments. It has its ſource in the department of the Somme, near Beaurevoir, a few miles to the north of Saint Quentin, a town of the department of the Aiſne; runs by Beauvoiſi, Catelet, Homécourt, Crévecœur, Cambray, Houdain, Bouchain, Neuville, Denain, Valenciennes, Fraine, and Condé, where it becomes navigable, after having received the Aiſne; it then flows to Mortagne, where it receives the Scarpe; from thence it goes on to Tournay, Gand, and Antwerp, where it is 701 metres, or 360 fathoms wide, and 10 metres, or 30 feet deep at low water; the tide at high water riſes 15 feet. After having paſſed Antwerp, the Eſcaut branches out into two channels; the eaſtern one paſſes by Bergen-op-Zoom, the weſt channel, called the Upper Eſcaut, loſes itſelf between the iſlands of Zealand into the North ſea, near Fleſſingue or Fluſhing. From Antwerp to this place its courſe is 74 miles; it widens gradually, and has pretty nearly the ſame depth every where; but its bed is obſtructed by ſand-banks, which render its navigation difficult and dangerous.

The Eſcaut has a communication with the river Somme by means of a canal, part of which is under ground.

Escaut, *the department of the*, is the ninth department of the firſt region or United Countries (pays réunis) of France, and derives its name from the river Eſcaut (Schelde) which traverſes it from ſouth to north. It is compoſed of part of Auſtrian Flanders; its chief place is Gand. The limits of the department of the Eſcaut are to the north, the kingdom of Holland; to the eaſt, the departments of the Dyle and of the two Nethes, from which it is ſeparated by the Eſcaut; to the ſouth, the department of Jemmapes, and to the weſt, that of the Lys. Its principal rivers are the Eſcaut, the Lys, the Durenn, the Liévre, the Dender, &c.

There are ſeveral canals in this department; that which goes from Gand to Bruges, and from Bruges to Oſtend, is the moſt important. Another towards the north opens a communication between Rodenherpen and Sao-de-Gand; a third one, near Morbeck, communicates by one of its branches with Axel, and by the other with Hulſt. There are alſo ſeveral leſſer canals for the purpoſes of irrigation, or of draining low marſhy grounds.

The ſoil is in general fertile, and produces all ſorts of corn and vegetables, chiefly hemp, flax, and hops. It abounds in game. Domeſtic fowls and ſweet water fiſh are plentiful. The chief manufactures are thoſe of linen yarn, linen cloth, cobalt, Pruſſian blue, ribbands, woollen cloth, earthenware, glaſs, writing paper. There are alſo ſeveral paper mills, ſugar-houſes, ſalt-works, and bleaching grounds.

The territorial extent of the department of the Eſcaut is 2888½ ſquare kiliometres, or 159¾ ſquare leagues; its population 595,258, or 3720 inhabitants to the ſquare league. The whole department is divided into four diſtricts, Gand, Audenaërd, Termonde, and l'Ecluſe; 41 cantons, and 338 communes. The average contribution of every individual to the expences of the ſtate is about 9*s.* 2*d.* ſterling annually. Herbin Statiſtique de la France.

Escaut *and Meuſe, the department of the*, in Dutch the department of the Schelde and Maas, is one of the new diviſions of the kingdom of Holland, and is reported to compriſe the weſtern part of the ancient Dutch Brabant, Zealand, and the iſlands of the Maas or Meuſe. Middleburg is its chief place.

ESCH, a town of the duchy of Luxembourg, on the Sour; 7 miles W. of Dicrich.

Esch, in *Ichthyology*, a name given by Hildegard and others to the fiſh we call the grayling, or umber, and the generality of authors, the thymallus. It is of the coregonous kind, and is diſtinguiſhed by Artedi by the upper jaw being longer, and the back fin containing twenty-three bones. The Germans call it *aſch*, and the Italians *temello*. See Salmo *Thymallus*.

ESCHALLOT, *Cepa Aſcalonica*, in *Botany*, a ſpecies of onion, cultivated in gardens for its uſe in cookery, and nearly reſembling the Welch onion. See Cepa.

ESCHAR. This term, in *Surgery*, implies a portion of fleſh, deadened by the application either of actual fire or cauſtic ſubſtances. In caſes of violent burns we frequently ſee eſchars produced; and whenever we wiſh to make a common iſſue, for the relief of any ſuch diſeaſe as a white-ſwelling, a caries of the vertebræ, &c. we cannot accompliſh our object better, than by forming an eſchar with the kali purum cum calce vivâ. The ſeparation of an eſchar, or its detachment from the living parts, is a work of nature, being chiefly effected by the action of the abſorbent veſſels, which remove the particles of matter, connecting the dead and living parts together, ſo as to looſen the eſchar, and allow it to be taken away, without pain, bleeding, &c.

ESCHARA, in *Natural Hiſtory*, the name of a ſpecies of coralline, &c. the characters of which are theſe: they are of a ſtony or coral-like hardneſs, and reſemble a woven cloth in their texture; and the microſcope ſhews us that they conſiſt of arrangements of very ſmall cells, whoſe ſurfaces appear much in that form. (See Millepora.) For other ſpecies, ſee Flustra and Madrepora.

ESCHAROPEPA, a word uſed by the old writers in *Medicine*, to expreſs a coarſe kind of barley-meal, which had been torrified over the fire.

ESCHAROTICS, in *Surgery*, are certain ſubſtances and applications which, when put on any part of the body, occaſion an eſchar, or ſlough. Although the ſtrict meaning of the word eſcharotic is the ſame as that of *cauſtic*, yet, modern practitioners uſually underſtand by the firſt term ſome application that is milder in its action, than ſuch ſubſtances as are denominated cauſtics. By the latter, a ſurgeon generally means the kali purum, with or without quicklime, or the argentum nitratum, antimonium muriatum, &c. But by eſcharotics he commonly implies applications like the cuprum vitriolatum, hydrargyrus præcipitatus ruber, &c.

The chief uſe of eſcharotics, in the practice of ſurgery, is to deſtroy excreſcences, funguſes, and high exuberant granulations. When mixed with ointment, ſo as to have their action weakened, they are alſo ſometimes employed for ſtimulating ſores, which are of an indolent nature.

ESCHATON, in *Muſic*, the difference between the dieſis enharmonica and the hyperoche; that is, what remains, after taking the difference between the ſemi-tone minor and dieſis enharmonica, from the latter. Henfling, in Miſc. Berolin. vol. i. p. 279, 280.

Thus the difference between the ſemi-tone minor and the enharmonic dieſis is $\frac{25}{24} : \frac{128}{125} = \frac{3125}{3072}$, and this taken from ſrom the dieſis, is $\frac{128}{125} : \frac{3125}{3072} = \frac{393216}{390625} = 6\Sigma - f + m$, and is the *major reſidual;* which ſee. This interval is about $\frac{53}{100}$ of a comma, as will eaſily appear by logarithms. Mr. Henſling has taken notice of this interval. He calls it eſchaton, from its being the leaſt and the laſt interval that occurs in his ſyſtem.

The word is Greek, εσχατον. See Interval.

Eschaton of Dr. Callcott's MSS., is an interval whoſe ratio is $\frac{16,677,181, \&c.}{16,777,216, \&c.} = 5\ \Sigma + 2\ f$, and is the *greater reſidual*, which ſee.

ESCHE, in *Geography*, a town of Switzerland, in the canton of Uri; eight miles S.E. of Altorff.

ESCHEAT, Eschet, or *Echet*, formed from the French *eſchoir*, or *échoir*, *to happen*, in *Law*, denotes an obſtruction of the courſe of deſcent, and a conſequent determination of the tenure, by ſome unforeſeen contingency; in which caſe the land naturally reſults back, by a kind of reverſion, to the original grantor or lord of the fee. (1 Feud. 86. Co. Litt. 13.) This was one of the fruits and conſequences of feodal tenure: and is incident to tenure in ſocage, as well as to tenure in knight-ſervice; except only in gavel kind lands, which are ſubject to no eſcheats for felony, though they are to eſcheats for want of heirs.

The civilians call ſuch eſcheats, or forfeitures, *bona caduca*; and in the ſame ſenſe, as we ſay the fee is eſcheated, they ſay *feudum aperitur*.

The word *eſcheata* ſometimes alſo ſignifies a lawful inheritance deſcending on the heir. But then it is uſually diſtinguiſhed by the addition of *recta*; as *recta eſcheata*.

Escheat is alſo uſed for the place or circuit within which the king, or other lord, hath eſcheats of his tenants.

Escheat is alſo ſometimes uſed for a writ, lying where the tenant having eſtate of fee-ſimple, in any lands or tenements holden of a ſuperior lord, dies ſeiſed without heir, general or ſpecial: in which caſe the lord brings this writ againſt him that poſſeſſes the lands, after the death of his tenant; and thereby recovers the ſame in lieu of his ſervices.

ESCHEATOR, an officer who anciently took care of the king's eſcheats in the county, and certified them into the exchequer, or chancery.

He was appointed by the lord treaſurer; held his office only for one year; nor could any perſon be eſcheator above once in three years. But this office, having its chief dependence on the court of wards, is now out of date.

ESCHEFELD, in *Geography*, a ſmall town of Saxony, near Wolfftitz, in the circle of Leipzick, remarkable for its quarries of beautiful jaſper, known by the name of Bandſtein von Gnandſtein.

ESCHEL, in *Mineralogy*, a term uſed by the ſmalt-workers, to expreſs a ſort of grey ſubſtance reſembling aſhes, which is uſually mixed with the ſmalt when in fuſion. This is carefully ſeparated from it before it is powdered for uſe, otherwiſe it would debaſe the colour. Phil. Tranſ. N° 396.

ESCHELLON, or Eçhellon, in the military acceptation, is a term borrowed from the French language, in which it ſignifies a ladder; alluding to the regular and parallel gradations of any ſeries of lines, more or leſs inclined from any given baſe line. Thus if we ſuppoſe in *fig.* 1. *Plate* I. *Tactics*, the line A B to be divided into any given number of equal parts, as 1, 2, 3, 4, 5, 6, and ſuppoſe the left end of each diviſion to be moveable on a pivot, the other end ſwinging round at pleaſure, we ſhall find that thoſe ſeveral diviſions are capable of being moved forward, at the aſſumed angles from the baſe line A B.

Now it is neceſſary to be well underſtood, that, according to the military ſtep, the number of files from any given pivot will determine the number of paces to be taken to make a wheel, correſponding with a right angle: thus when the 8th file from the pivot makes eight paces in wheeling, the whole of the diviſion performing ſuch evolution will make a wheel equal to the quarter of a circle, becauſe all diſtances from the centre muſt invariably correſpond with the quarter of a circle, of which ſuch diſtances are reſpectively radius.

But the eçhellon movements are never underſtood to amount to the quarter of a circle; that being conſidered a full wheel, changing from line into column: yet the eçhellon is itſelf a ſpecies of column, diſpoſeable with equal promptitude either to flank or front; thus affording peculiar advantage, while it gives at the ſame time a parallel movement of a line, broken for the moment, into ſmall portions, towards any object obliquely ſituated towards either flank; in front or rear. Theſe important advantages have not been overlooked by modern tacticians, who have amply availed themſelves of the mutability thus afforded: conſequently we find the eçhellon adopted in the exiſting code of evolutions, on an unlimited ſcale.

It being aſcertained that the eighth file, by moving forwards eight paces in a regular curve on the given pivot, makes a wheel of one quarter of a circle; it is obvious, that any intermediate part, of which one pace is the multiple, may be wheeled, by taking the deſired number of paces; thus, four paces will make an octave, or the eighth part of a circle, which is the moſt frequent declination from the baſe line; two paces will give the ſixteenth of a circle, or the fourth part of a quadrant; and thus of any number.

Let us ſuppoſe it requiſite to change the front of a battalion to a new poſition, forming, as nearly as the eye could eſtimate, an angle of 75° from the baſe line A B. Now, as each ſtep of the eighth file gives a change of front equal to about eleven degrees, it is obvious, that ſeven ordinary paces will rather exceed the given angle; therefore, if very great preciſion ſhould be indiſpenſable, the eighth file ſhould make ſix long, and one ſhort pace, which would throw the whole battalion into eçhellon at ſuch an angle as would allow the ſeveral diviſions to march with a full front to their poſitions in the new line. This is a moſt important object; becauſe it admits the utmoſt freedom of individual movement, and avoids that oblique tendency which muſt be reſorted to whenever ſuch full frontage cannot be preſerved.

Eçhellon may be formed towards either flank; whether to the rear or to the front; the open column may be readily formed by wheeling ſo as to complete the quarter of a circle, including the original portion, and adding it to the ſupplement: both wheels being in the ſame direction. Thus if only the eighth of a circle was wheeled into eçhellon, another wheel, of another eighth, will be needful to bring the corps into open column.

To form the line from eçhellon; either a back wheel may be made equal to the wheel forward: thus, if a battalion has broken into eçhellon by wheeling an octave *to* the right, it will, by wheeling *back* an octave *on* the right of diviſions, be inſtantly formed into line. In this inſtance the right flank gives the point d'appui. But if the left is to give it, there the whole of the diviſions muſt wheel *forward* on their left pivots, as many degrees as were included in the original wheel to the right. If the firſt wheel was only the

16th part of a circle to the right, the complementary wheel to the left muſt be equal to only one ſixteenth. In ſaying this, it is neceſſary to be underſtood, that all the diviſions are ſuppoſed to be of equal ſtrength; otherwiſe it will be indiſpenſably neceſſary that the reſpective pivots, which are to guide the alignement, be properly dreſſed; that is, cover correctly, before any wheel is made under their guidance.

Eçhellon diviſions do not always move with a full front towards that point on which the wheel is made; on the contrary, it is often expedient to wheel to the right, when the new front is towards the left. This is done for the purpoſe of giving the flanks of the diviſions a proper direction, that they may reſpectively march by files, towards their ſtations in the new line; and is particularly neceſſary in broken ground, as well as in countries covered with wood. The ſeveral leaders of files muſt, in this caſe, be extremely correct in maintaining their original direction; attending to their ſeveral pivot-men, if ſuch be in ſight: where that guide cannot be afforded, the greateſt care muſt be taken to obſerve any two diſtant objects that may be in the given direction; ſo as to proceed, as nearly as poſſible, to the appointed ſpot.

From the foregoing it will be collected, that, while *direct* changes of front are made by full wheels (*i. e.* the quarter of a circle,) to either right or left, oblique changes are effected by means of a due degree of paralleliſm, produced in conſequence of wheeling in any proportion leſs than the quarter of a circle. Therefore, as the code of regulations now in uſe for the movements of battalions properly inculcates, the eçhellon poſition and movements are not only neceſſary and applicable to the immediate attacks and retreats of great bodies; but alſo to the previous oblique or direct changes of ſituation, which a battalion, or a more conſiderable corps, already formed in line, may be compelled to make, to the front or the rear, or on a particular fixed diviſion of the line.

When a battalion marches in eçhellon its route muſt be on the reverſe principles of Marquois's parallel rule, which conſiſts of a ſcale, having a triangular piece ſliding at liberty along its edge, as ſhewn in *fig.* 2. In that the inclined plane A B even follows a line not perpendicular to its front, and this is the main diſtinction between the eçhellon movement and the oblique-ſtep; the former may continue for any diſtance, rather giving eaſe, than proving unuſually fatiguing, to the men; whereas the oblique-ſtep is peculiarly diſtreſſing, if kept up for a length of time; while it beſides poſſeſſes the great diſadvantage of gaining but little ground. In the above figure the line A B may proceed the whole length of C D, without gaining ground towards its oppoſite, or exterior flank B; becauſe it is, in a manner, fixed by the inner flank A, which may be ſaid to run in a groove on the line B C; whereas if we applied the eçhellon movement to the line A B, that is perpendicular to its own front, its courſe would be according to A E, B F, and ground would be gained to its right, as well as to its front, in exact proportion to the angle D A B; if that be ſmall, there will be a greater tendency to the front of the line C D, than towards its left flank, and *vice verſâ*; ever carrying in mind, that ſo ſoon as the wheel amounts to a quarter of a circle, the term eçhellon is annulled.

We ſhall here exhibit the uſe of an eçhellon movement as applicable to the reinforcing of a line advancing at the *debouchure* of a *detroit*; where, in conſequence of the regular expanſion, it becomes neceſſary to keep adding to either, or perhaps to both flanks, in order to prevent the enemy from penetrating; ſo as to attack the rear. It may be expedient to obſerve that not only companies, but whole battalions, may form in eçhellon; and that it is an evolution ſuited equally to cavalry and to infantry. When a park of artillery has to flank an enemy, in a poſition where the proper line cannot be aſſumed, ſo as to bring the ſeveral guns to a line perpendicular to the direction of their fire, they muſt then, properly ſpeaking, be individually in eçhellon. Thus when guns are mounted in *barbet*, (*i. e.* where there are no embraſures, the muzzles traverſing over the parapet,) whenever the object does not bear at right angles with the face of the battery, each gun is obliqued, and the ſhots fired from the whole would repreſent the movements of diviſions thrown into eçhellon. *Fig.* 3. ſhews a line forming as the army iſſues from a detroit, the ſeveral battalions compoſing it being allowed to reinforce the centre until due ſpace be gained for the whole to wheel into eçhellon. Now it will be ſeen, that each battalion formed in column, in by files, ſucceſſively aſſumes a poſition perpendicular to that line; but, that when ſpace admits, the wheel is made, whereby each diviſion is directed towards the poſt it will occupy on the flank, as the expanſion takes place. Here S S is the line, and O P the battalion deſtined to cover the right flank; its ſeveral diviſions, being thrown into eçhellon, muſt in their progreſs fall into their reſpective poſts, at the new poſition *a a* one after the other, filling up the augmenting ſpace with celerity and exactneſs. It is, however, to be underſtood, that each, as it approaches its ſituation in line, muſt accelerate or retard its pace according to circumſtances; ſince it cannot be expected that the ground will expand with perfect regularity.

In caſe of an attack, in which the enemy may ſucceed in getting round the flank, thoſe diviſions cloſe to that flank muſt wheel back into line; leaving to two or three of the rear diviſions to join on their flank in the direction of the eçhellon front; thus forming a re-entering angle, effectually cutting off the enemy's progreſs, and ſubjecting him to a concentrated fire; as ſhewn by the dotted poſitions at E. The dotted lines emanating from the ſeveral eçhellons ſhew their direction when marching: their prolongation would ſhew how they would fall in on the flank, ſo as gradually to extend the front; compleating the new line *a a*. When neceſſary, the ſame operation is performed towards the left.

It has been obſerved that the eighth file gives a determinate meaſurement, in regard to the wheel of diviſions into eçhellon; it is therefore expedient, when the given direction is aſcertained, to cauſe the eighth file to ſtep out the required diſtance, (ſay four paces for the eighth of a circle,) obſerving, that his advance muſt be on a wheeling principle: that is to ſay, curved; the pivot being conſidered as the centre, and the diſtance between that and the eighth file being radius. Each diviſion thus ſending forth its eighth file, the whole are ordered to wheel until thoſe files are reſtored to their places in their diviſions: during the wheel of the diviſions, each muſt neceſſarily remain motionleſs; that all may dreſs by them; ſo as to give a true parallel throughout the line of eçhellon.

ESCHENAU, in *Geography*, a town of Germany, in the archduchy of Auſtria; eight miles S. of St. Polten.

ESCHENBACH, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles E.N.E. of Nuremberg.

ESCHENBERGA, a ſmall town of Germany, in the duchy of Saxe Gotha, with a population of 504 inhabitants, remarkable for its trade in madder. It was anciently of more importance.

ESCHERSHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg; 10 miles.

10 miles W. of Hanau, and 3 N.N.W. of Francfort on the Main.

ESCHEVIN, or Echevin, *Scabinus*, in the French and Dutch *Polity*, a magiſtrate elected by the inhabitants of a city to take care of their common concerns, the good order, conveniency, and decoration of the city, &c.

At Paris there is a prevot and four eſchevins; in moſt other cities a maire, or mayor, and eſchevins. In Languedoc, Provence, and Dauphiné, they are called *conſuls*; at Thoulouſe *capitouls*; and *jurats* at Bourdeaux.

Anciently, the eſchevins were the aſſeſſors and counſellors of the comites, or judges of cities; on which account they were called, in ſome places, *pairs*, *pares*; they even took cognizance of petty cauſes themſelves.

Du-Cange obſerves, that the judges, and their aſſeſſors, who were choſen by the inhabitants, were called *ſcabini*, eſchevins, and their college, *ſcabinagium*, or *eſchevinage*. He adds, that ſome authors call them *paciarii*, becauſe their office and juriſdiction extended to the ſecuring peace in their city and baulieue, called *pax villæ*.

In Holland, the *ſcabins*, or eſchevins, judge of all civil affairs at firſt hand. They alſo take cognizance of criminal matters; and if the criminal confeſs himſelf guilty, they can ſee their ſentence executed without appeal. They can even give torture. The number is not the ſame in all cities; at Amſterdam there are nine, at Rotterdam ſeven, &c.

ESCHLBERG, in *Geography*, a town of Germany, in the archduchy of Auſtria; 14 miles S.W. of Freuſtadt.

ESCHLKAMP, a town of Germany, in Lower Bavaria; 3 miles E. of Furth.

ESCHRAKITES, or Esrakites, a ſect of philoſophers, among the Mahometans, who adhere to the doctrines and opinions of Plato.

The word is derived from the Arabic שרק, *ſchraka*, which in the fourth conjugation אשרק, *aſchraka*, ſignifies *to ſhine, glitter like the ſun*; ſo that Eſchrakite ſeems to import *illumined*.

The Eſchrakites, or Mahometan Platoniſts, place their higheſt good and happineſs in the contemplation of the Divine Majeſty; deſpiſing the groſs imaginations of the Alcoran touching Paradiſe. See Mahometanism.

They are very careful in avoiding all vice; they preſerve an equal and eaſy temper, love muſic, and divert themſelves with compoſing little poems, or ſpiritual ſongs. The ſheics, or prieſts, and the chief among the preachers of the imperial moſques, are Eſchrakites.

ESCHWEGE, in *Geography*, a ſmall town of Germany, in the landgraviate of Heſſe Caſſel, which now forms part of the new kingdom of Weſtphalia. It is ſituated on the Werra, 33 miles E. of Caſſel, near a lofty hill called the Meiſner, which has ſome coal-mines. Eſchwege is a place of high antiquity.

ESCHWEILLER, a ſmall town of France, in the department of the Roer, chief place of a canton, in the diſtrict of Aix-la-Chapelle, with a population of 1713 individuals. The canton has 18,588 inhabitants, diſperſed in 28 communes.

ESCHYLUS. See Æschylus.

ESCHYNOMENOUS Plants. See Æschynomenous.

ESCLAIRCISSEMENT, or Eclaircissement, a French term, which we find retained in ſome late Engliſh writers; it properly ſignifies the act, or effect, of clearing a thing, or rendering it more bright and tranſparent; being formed from the verb *eſclaircir*, to clear, &c. It is chiefly uſed in a figurative ſenſe, for an explanation of an obſcurity or difficulty. The eſclairciſſement of difficult paſſages in the bible, is to be ſought for from ſimilar paſſages, or paſſages of the like kind occurring in other places.

ESCLAME, in the *Manege*, an obſolete French word, formerly uſed to ſignify a light-bellied horſe.

ESCLATTE', in *Heraldry*, is applied to a thing violently broken. Thus a bend or rather partition, eſclatté, is repreſented torn, or broken off, like a ſhield ſhattered with the ſtroke of a battle-ax.

ESCOBAR, Anthony, ſurnamed *De Mendoza*, in *Biography*, a Spaniſh Jeſuit, who flouriſhed in the beginning and middle of the ſeventeenth century. The opinions which he maintained have been cenſured by more modern writers; and the principles of his morality have been expoſed by Paſchal in his "Lettres Provinciales," and by other authors of leſs note. He left behind him many works, among which are "Theologia Moralis;" "Commentaria in Vetus et Novum Teſtamentum;" and "Examen y Pratica de Confeſſores." Moreri.

ESCOL, in *Ancient Geography*, a valley or torrent of Paleſtine, in the ſouthern part of the tribe of Judah; mentioned in the book of Numbers.

ESCORT, in *Military Affairs*, ſignifies that guard granted, either under military authority, or of military perſons, for the ſafe conveyance of perſons, property, &c. from one place to another. This may be ſaid to diſtinguiſh an eſcort from a convoy; the latter being generally applicable to ſuch extenſive affairs as relate rather to the guarding of ſupplies, &c. on their way to an army, or to a fortreſs. The extent of an eſcort is uſually proportioned either to the dignity of the perſon attended, if it be meant as a compliment; or, if of treaſure, according to the ſum, and the dangers lying in the way. In ſome caſes, eſcorts are taken only from particular corps; as, for inſtance, thoſe which attend upon his majeſty, which are ſelected from certain regiments only, unleſs on extraordinary occaſions. When an eſcort is employed on ſuch an occaſion, its commander is uſually placed under the orders of the perſon to be guarded; but when treaſure, priſoners, &c. are in queſtion, the commander is in every reſpect paramount; he being reſponſible for the ſafe arrival, and the delivery, of whatever is under his charge. Such is the ſtrictneſs with which the reſponſibility of an eſcort is upheld, that a few years back, when a deſerter who was under charge of a guard made an attempt to abſcond, one of the party fired at him, but unhappily miſſing the fugitive, killed an unfortunate paſſenger in the ſame ſtreet; the man who fired was conſidered to have done no more than his duty. We naturally view ſuch an occurrence with much concern, and commiſerate the ſufferer; but when we contemplate what might have been the ſituation of the ſoldier, had he omitted to do his beſt towards preventing the eſcape, though we cannot exactly applaud his conduct, we muſt aſſuredly ſee much in extenuation of the manſlaughter.

When travelling any diſtance, and that ſpeed is eſſential, it is uſual to relieve the eſcorts, when convenient, at certain ſtages. In ſuch caſe, it behoves the commander of each party to be very careful in examining every matter previous to taking charge. If there be treaſure, or other valuables, &c. under ſeal, the impreſſions ſhould be minutely inſpected; and if the articles, or packages, be numerous, but more eſpecially if ſubject to damage, he ſhould cauſe the whole to be counted, and aſcertain, in the preſence of the perſons from whom he receives them, the exact ſtate and appearance, noting every point worthy of obſervation in the way-bill, and excluſively giving a receipt, in which all caſualties or deficiencies ſhould be fully deſcribed. This inſpection ſhould always be made in the preſence of others of his own party, and it would not be amiſs were he to cauſe them to atteſt the condition in which the articles ſhould be, at the time of his receiving charge. Should any accident take place while under his own protection, the hour, the place, and the cauſe, ought to be in like manner noted, ſo ſoon as poſſible, under the certificate of credible perſons on the ſpot; or at leaſt of ſome of his own party. By ſuch precautions much imputation will be avoided; while at the ſame time a character for correctneſs, and for aſſiduity, will be gained.

ESCOT, L', in *Geography*, a ſmall town of France, in the department of the Lower Pyrenées; 6 miles S. of Oleron, remarkable for a cooling mineral ſpring.

ESCOUADE, or SQUAD, is uſually the third or fourth part of a company of foot; ſo divided for mounting guards, and for the more convenient relieving of one another. It is equivalent to a brigade of a troop of horſe. See BRIGADE.

ESCROL, or SCROLL, in *Heraldry*, a long ſlip, as it were, of parchment, or paper, wherein a motto is placed.

Leigh obſerves, that no perſon, under the degree of a knight, might, long after king Henry V. place his creſt on a wreath, as is now uſually done, but only on an eſcrol.

ESCROW, in *Law*, a deed delivered to a third perſon, to be the deed of the party making it upon a future condition when ſuch thing is performed; and then it is to be delivered to the party to whom made. It is to be delivered to a ſtranger, mentioning the condition; and has relation to the firſt delivery. 2 Roll. Abr. 25, 26. 1 Inſt. 31. See DEED.

ESCU, or ECU, the French crown, of ſixty ſols, or three livres. The eſcu was thus called, becauſe the eſcutcheon, or arms of France, which they call eſcu, was ſtruck thereon. See COIN.

ESCU, *Emaux de l'*. See EMAUX.

ESCUAGE, or SCUTAGE, an ancient kind of knight's ſervice, called alſo "ſervice of the ſhield;" the tenant holding by which was obliged to follow his lord to the Scottiſh or Welſh wars, at his own expence. But perſonal attendance being inconvenient, the tenants compounded for it by a pecuniary ſatisfaction, which was levied by aſſeſſments at a certain rate for every knight's fee; and thus it became a pecuniary in lieu of a military ſervice. The firſt inſtance that occurs was in 5 Hen. II. on account of his expedition to Toulouſe; it afterwards became more general and oppreſſive; ſo that king John was obliged to conſent, by his Magna Charta, that no ſcutage ſhould be impoſed without conſent of parliament; but the clauſe was omitted in the charter of Hen. III. which directs, that it ſhould be taken as it is uſed to be in the time of Henry II. or in a reaſonable and moderate manner. However, it was afterwards enacted by ſtat. 25 Edw. I. cap. 5 and 6. and many ſubſequent ſtatutes, that the king ſhould take no aids or taſks but by the common aſſent of the realm; and it appears that ſcutages were the ground work of all ſucceeding ſubſidies, and of the land-tax of later times. Blackſt. Com. vol. ii. p. 74.

ESCUAGE was alſo a reaſonable aid, demanded by the lord of his tenants, who held of him by knight's ſervice. See AID.

"Conceſſerunt domino regi ad maritandum filiam ſuam de omnibus qui tenent de domino rege in capite de ſingulis ſcutis 20 ſolidos ſolvendos." Matt. Paris, anno 1242.

ESCULAPIUS. See ÆSCULAPIUS.

ESCULENT, in *Gardening*, is a term frequently applied to ſuch roots or plants as are replete with nutritious matter, and conſequently proper for being eaten as a food. Carrots, parſnips, turnips, cabbages, and various others of a ſimilar nature, are of this kind.

ESCULUS, in *Botany*, a name given by many authors to the phagus, or ſweet oak, called alſo the eſculent oak.

ESCULUS, or *Æſculus*. See ÆSCULUS.

ESCURA, in *Geography*, a province of the empire of Morocco, called by Leo Africanus *Aſcora*, which, together with that of Ramna, formerly compoſed only one government. It has been divided to keep the people of theſe countries, ſo near to the mountains, more eaſily in ſubjection. Ramna and Eſcura have the province of Morocco to the ſouth, that of Duquella to the weſt, the river Morbeya to the north, and mount Atlas to the eaſt.

ESCURIAL, by the Spaniards written *Eſcorial*, a term that denotes the place of reſidence of the kings of Spain. Eſcurial originally ſignifies a little village in Spain, ſituated in the kingdom of New Caſtile, 22 miles to the N.W. of Madrid, on the ſide of a chain of mountains, called by ſome the Carpetane, or Carpentanian mountains, and by others the Pyreneans, as being the branch of the Pyrenean ridge, and environed by wood-lands and green fields. Here king Philip II. built a ſtately monaſtery of the order of St. Jerom, held by the Spaniards for one of the wonders of the world, and called the Eſcurial. It was begun in 1557, and finiſhed in about twenty-two years, at the expence of ſix millions of piaſtres.

Fa. Franciſco de los Padros, in a deſcription thereof, intitled "Deſcription breve del Monaſterio de S. Lorenzo el real del Eſcorial, &c." aſſures us it was built by that prince in memory of the battle of St. Quintin, gained on the day of St. Laurence, Lorenzo, a famous Spaniſh ſaint, and at his interceſſion; accordingly the plan of the work reſembles a gridiron, the inſtrument of the ſaint's martyrdom.

The king and queen have their apartments there; the reſt being poſſeſſed by the monks. Whence many of the great tranſactions of that court are dated from the Eſcurial.

This ſuperb palace is a long ſquare, 740 by 580 Spaniſh feet, beſides 460 for what may be termed the handle of the gridiron. The height of the roof is 60 feet; and at every angle is a ſquare tower, 200 feet high. In the weſt front there are 200 windows, and 366 in the eaſt.

The Eſcurial has a very fine church, the dome of which is 330 feet, ſupported by four rows of pillars, and paved with black marble, containing 40 chapels, and 48 altars. To this church Philip IV. annexed a beautiful mauſoleum, called the Pantheon, or Rotondo, built on the plan of that temple at Rome, 36 feet in diameter, and incruſted with marble; in which the kings and queens of Spain, who leave any poſterity, are interred; the reſt being laid in another vault of the ſame church, together with the infantas, and other princes.

The palace poſſeſſes every convenience and ornament that can render a place agreeable in ſo hot a climate; ſuch as an extenſive park, groves, fountains, caſcades, grottos, &c. The adjacent country contains ſpecimens of all the mineral ſubſtances, ſtones, earths and vegetables, which are found in other parts of the kingdom. The library belonging to this palace is ſaid to conſiſt of 30,000 volumes, contained in two magnificent apartments, each 194 Spaniſh, or ſomewhat more than 182 Engliſh feet in length. In the lower room are chiefly printed books; and in this is depoſited the famous MS. of the four goſpels, written in gold letters, ſaid to be a work of the 11th century. Over theſe are collected 4500 MSS., of which 567 are Greek, 67 Hebrew, 1800 Arabic, the latter of which are well deſcribed in a catalogue publiſhed by Caſiri. In the middle of the lower room is a temple, with a great variety of figures, containing 1448 ounces of ſilver, and 43 of gold, beſides rich gems. In every part of the convent of the Eſcurial, are ſeen the works of the beſt maſters, and ſome of them moſt capital performances. The beſt of the pictures are collected in five principal apartments; the great ſtaircaſe is beautiful, adorned with freſco-paintings of the battle of St. Quintin, by Luca Jordano. The ſituation of the Eſcurial, as a reſidence, is not pleaſant: expoſed, as it is, to the full ſtroke of the meridian ſun, and raiſed up near to regions covered with eternal ſnow; without ſhelter and deſtitute of ſhade, it has no local charms at any ſeaſon of the year. (Townſend's Travels, vol. 2.) Part of this ſuperb palace was burnt in 1671.

ESCUROLLES, in *Geography*, a ſmall town of France, in the department of the Allier, chief-place of a canton, in the diſtrict of Gannat, with a population of 1042 individuals. It is 6 miles N. of Gannat. The canton contains 15 communes, and 11,408 inhabitants, on a territorial extent of 237½ kiliometres.

ESCUTCHEON, or SCUTCHEON, in *Heraldry*, the field or coat, wherein the bearing, or arms, of any perſon are repreſented.

The word eſcutcheon is formed of the French *eſcuſſon*, and that from the Latin *ſcutum*, ſhield; which was the place arms were originally borne on, before ever they came on banners; and ſtill, wherever they are placed, it is on ſomething repreſenting the form of a ſhield. The Latin *ſcutum*, no doubt, came originally from the Greek, *σκυτος*, *leather*, wherewith the ſhields were uſually covered. See SHIELD.

The eſcutcheon is of a ſquare figure, excepting the bottom part, which is uſually a little rounded, ending in a point in the middle.

Till within a few hundred years, the eſcutcheons of the French and Engliſh were triangular; thoſe of the Spaniards are ſtill quite round at bottom, without any point; thoſe of the Italians are oval; and thoſe of the Germans in form of a catoozes.

The ancient eſcutcheons were generally couched, or inclined; and they only began to place them upright, when crowns, &c. were put over them by way of creſt.

In France *eſcuſſon*, eſcutcheon, was formerly reſtrained to a ſhield, or coat, pointed at bottom; by which it was diſtinguiſhed from the eſcu, which was quite ſquare, and was only allowed to be borne by the counts and viſcounts. Thoſe of the inferior quality were confined to the eſcuſſon or pointed eſcu.

The ſeveral parts or points of the eſcutcheon have their proper names: the point A, for inſtance, is the dexter chief point; B the middle chief; and C the ſiniſter chief point; D is the honour point; E the feſſe point; F the nombril point; G the dexter-baſe; H the middle; and I the ſiniſter baſe point. See *Plate* of *Heraldry*.

The dexter ſide of the eſcutcheon anſwers to the left hand, and the ſiniſter ſide to the right hand of the perſon that looks on it.

The eſcutcheon is differently denominated, according to its diviſions. It is called dextered, when the perpendicular line that divides it is to the right of a third part of the eſcutcheon; ſiniſtered, when on the left; tierced in pale, when this line is double, and divides the whole eſcutcheon into three equal parts; paled, when increaſed to the number of ſix, eight, or ten. A horizontal line makes the chief, when at one third part from the top; the plein, when at a third from the bottom; and when double, in the middle at an equal diſtance from both extremes, it makes the feſſe, and the tierced in feſſe: when it is multiplied, it denominates it feſſed; when there are eight or ten equal ſpaces burrelle. A diagonal from the dexter point of the chief to the ſiniſter of the baſe, makes it tranché; the contrary doublé; if it be double at equal diſtances the firſt makes bandé, and the tierce in bend; and the other barre, or tierce in bar; increaſing the number of the firſt makes bandé, and cotticé; and increaſing that of the ſecond barré, and traverſe.

ESCUTCHEON *of pretence*, is an ineſcutcheon, or little eſcutcheon, which a man who has married an heireſs, and has iſſue by her, may bear over his own coat of arms, and in it the arms of his wife; and, in this caſe, the ſurviving iſſue will bear both coats quarterly.

ESCUTCHEON, in *Sea Language*, a name ſometimes given to the compartment for the names or arms of the owner, or of the perſon whoſe title the veſſel aſſumes. It is uſually fixed on the middle of the ſhip's ſtern; and is more peculiar to the French, and other foreigners, than to Engliſh-built veſſels. Falconer.

ESCUTCHEON, *Secret*, is a contrivance to be placed before a lock, which cloſes up, and conceals the key-hole, and renders it inacceſſible for any perſon except the owner, who is acquainted with the ſecret.

The marquis of Worceſter appears to have invented ſome ſecret eſcutcheons, for in his "Century of Inventions," publiſhed in 1663, at N° 72, after having ſpoken of three kinds of locks invented by him, ſays, "an eſcutcheon to be placed before any of theſe locks with theſe properties:

"The owner, though a woman, may with her delicate hand vary the ways of coming to open the lock ten million times beyond the knowledge of the ſmith that made it, or of me who invented it."

Many attempts have been made to form a machine equal in its properties to the deſcription here given; and from thence, it is probable, aroſe the kind of padlocks which have been long made in this country, in great numbers, which having ſeveral letters on different rings, can only be opened when a certain ſet of thoſe letters is arranged in one order; but this was in no degree equal to the end propoſed; for beſides the workman who made it, being at all times informed of the poſition the letters muſt be in, and conſequently enabled to open it, the letters and rings admitting of no variation of place, at the will of the owner; reſerving, at the ſame time, a power of opening the locks; whenever the proper arrangement became known, the ſecret was divulged, and all ſecurity at an end; but by the improvement lately made by Mr. Marſhall (for which the Society of Arts rewarded him with ten guineas,) the letters or figures allowing an almoſt infinite variety of changes, the owner may, in one minute, alter the ſecret in ſuch a manner, that even the maker would be as unlikely to open it, as he would be of gaining the higheſt prize in a lottery, by the chance of a ſingle ticket. Thus this kind of eſcutcheon is infinitely more ſecure than any hitherto in uſe, eſpecially as the alteration of the letters may be made every day for years, without recurring to their firſt ſtate; and as the owner may at one time chuſe to truſt a friend, or a domeſtic with the ſecret, ſo that they might have recourſe to his valuables, &c. he may alſo at another time wiſh to exclude them from that privilege, which this contrivance renders very eaſy to be done. As this improvement relates only to the eſcutcheon, it is obvious that every attempt to pick the lock it covers, or to open it by means of falſe keys, is prevented; a circumſtance of no ſmall importance, when locks of a curious conſtruction, and when a number of fine wards are made uſe of.

The eſcutcheon for which the bounty was given is reſerved in the repoſitory of the ſociety for the inſpection of the public.

Figs. 2, 3, 4, 5, 6, 7, 8, and 9, *Plate* XII. *Miſcellany*, repreſent this contrivance: *fig.* 3. is a view from behind the machine, ſuppoſing it to be firſt removed from the door. *Fig.* 2. is an elevation of the machine, as it appears upon the door; A B C D is a braſs box, faſtened over the key hole; it has a ſquare hole through it, covered by a ſmall door E; this door is kept ſhut by a pin fixed into a ſmall lever *a*, *fig.* 3, which enters a projection from the ſide of the door, and thus prevents it being open, unleſs the lever is firſt drawn back; a ſpring *b* is applied behind the lever to force it outward, and another at E always preſſes againſt the door, and acts to throw it open as ſoon as the lever *a* is drawn back, which is accompliſhed by means of a pin, which comes through a groove in the plate; this pin is faſtened in a ſquare bar F, *figs.* 2 and 5. (ſhewn ſeparately in *fig.* 4.) on the front of the plate. The ſmall perſpective, *fig.* 8. repreſents two braſs cocks *d*, *d*, which ſupport the ends of a cylindric wire *g*, in which is a groove for the bar F to ſlide backwards and forwards; theſe cocks are ſcrewed to the plate within-ſide, as ſhewn at *d d*, *figs.* 2, 3, and 5, and come through an opening in the Plate; ſo that the bar F is in front of the plate; the wire *g* is the common axis for five ſmall rollers *a*, *c*, *ſ*, *m*, *o*, the ſtructure of one of theſe is explained by *figs.* 5, 6, 7, and 9; *b* is a circular piece of braſs which fits upon the centric wire: this, as is ſhewn in the ſections, *figs.* 5 and 9, is thicker at the outſide than the middle; and the front view, *figs.* 6, 7, ſhew how a receſs is cut, communicating with the centre hole; now when the five rollers are turned round upon the central wire *g*, ſo that the receſſes are all brought into the front, the projecting teeth *x*, *x*, of the ſlider F will meet with no obſtruction, and may be drawn back ſo as to open the eſcutcheon; but when any of the rollers are turned round, ſo that the thin parts near the centre are brought between the teeth of the ſlider, then the ſlider cannot be withdrawn. The poſition of the roller, when the ſlider is at liberty, is known by bringing five of the letters which are engraven on the outſide of the rollers uppermoſt, and it is in theſe letters that the ſecret conſiſts. But to render the combination of letters variable, the letters are not engraved upon the outſide of the rollers themſelves, but upon a thin braſs hoop *e*, which is fitted on round the roller; a ſpring *n* is faſtened to the roller, and preſſing upon the inſide of the hoop cauſes ſuch a friction, that they go together in general; but when the ſecret is to be changed, the ſlider F muſt be drawn partly back, ſo that its teeth *x* come in the way of the thin parts of the rollers, and they cannot, therefore, be turned round; the outſide hoop *l* is then forced round upon the inſide one, and a freſh letter brought oppoſite the receſs; by this operation the ſecret is altered, and the eſcutcheon cannot be opened till the ſame combination is produced. Each roller has four letters upon it, in all twenty letters, and the combinations which they are capable of are ſo numerous, that the chance is ſtrongly againſt any perſon not acquainted with the ſecret opening it.

Escutcheon-*grafting*. See Grafting.

ESDEN, in *Geography*, a town of Germany, in the kingdom of Weſtphalia, and biſhopric of Liege; 3 miles S.S.W. of Stocklim.

ESDRAELON, or Esdrela, in *Ancient Geography*, a village of Paleſtine, in the tribe of Iſſachar, the ſame as Jezreel, 10 miles from Scythopolis, according to the old Itinerary. (Joſh. xix. 18.) It gave name to a plain, which extended eaſt and weſt from Scythopolis to mount Carmel; called likewiſe the "Great Plain," the "Valley of Jezreel," and the "Plain of Eſdrela,"

ESDRAS, See Ezra. We have four books of ſcripture under the name of Eſdras; of which, only the two firſt are acknowledged as canonical; and they were formerly reckoned by the Hebrews as one, according to St. Jerom. The firſt of theſe is allowed to be the work of Ezra; for he relates events of which he was witneſs, and often ſpeaks in the firſt perſon. Some, however, have ſuppoſed that the ſix firſt chapters were compoſed by a more ancient writer; and they allege, that the author of theſe chapters was at Jeruſalem in the time of Darius the ſon of Hyſtaſpes. (Ch. v. 4.) From this paſſage it is inferred that the writer was then at Jeruſalem; but Ezra did not come thither till the reign of Artaxerxes, as appears by the beginning of the 7th chapter. To this argument it is replied, that Ezra ſpeaks in the name of the Jews, and that it is uſual for hiſtorians of a country to ſpeak in the firſt perſon in the name of their own nation, although the hiſtorians themſelves had no participation in the events which they record. Another difficulty occurs in explaining the genealogy and number of thoſe who returned from Babylon to Jeruſalem under Nehemiah, mentioned in the ſecond chapter, and related in the ſame manner, though with ſome additions and alterations in the 9th chapter of Nehemiah. Some ſuppoſe that Nehemiah tranſcribed this out of the book of Ezra, adding the names of thoſe perſons who came to Jeruſalem in the ſecond return from the captivity. Others, on the contrary, imagine that Ezra copied the paſſage from Nehemiah, ſince mention is made in it of Nehemiah. Others pretend that the genealogy of Ezra was afterwards corrected from that of Nehemiah. However, none of theſe conjectures are reconcileable with the differences that occur in the two genealogies. But after all, there is no neceſſity for ſuppoſing that one of theſe authors tranſcribed from the other, for they might both of them have written theſe genealogies: Ezra having ſurvived the ſecond tranſmigration made under Nehemiah, and not having written his book till the latter end of his life. The ſecond book under the name of Ezra, is attributed to Nehemiah; though ſome inconſiderable particulars have been added to it, which cannot belong to Nehemiah: ſuch as the mention of the high-prieſt Jaddua, and king Darius. (Neh. xii. 22.) This Jaddua is Jaddus, in whoſe time Alexander the Great came to Jeruſalem; and Darius is Darius Codomannus, overcome by Alexander 100 years after Nehemiah. The firſt of theſe two books contains the hiſtory of the deliverance of the Jews from the captivity of Babylon, and of their re-ſettlement in Judea, from the firſt year of Cyrus to the 20th of Artaxerxes Longimanus; and the ſecond begins at the 20th year of the ſame prince, to the reign of Darius Nothus. The chronology of this ſpace of time depends on the duration of the reigns of the kings of Perſia.

The third book, under the name of Eſdras, is thought by the Greeks to be canonical. Its author is not known, but he is ſuppoſed to have been an Helleniſt Jew. The book is the ſame in ſubſtance as the firſt of Eſdras, but interpolated; and in different parts of it we have a ſummary repetition of the two laſt chapters of the ſecond book of Chronicles, as well as of the books of Ezra and Nehemiah. Againſt its authority there are ſeveral material objections, for which we refer to Arnald's excellent Commentary on the Apocrypha, p. 122;

The fourth book of Eſdras is written with ſufficient art, as if Eſdras himſelf had compoſed it; but the marks of falſhood are diſcernible in it. Neither the Synagogues, nor the Greek or Latin church ever unanimouſly received it as canonical; though ſome of the fathers have cited it, and the Latin church has borrowed ſome words out of it. It is not now extant in Greek; and it never was in Hebrew. It ſeems moſt probable that the author was a Jew, converted to Chriſtianity, who, in hopes of converting others, compoſed this work under the name of a writer, for whom the Jews had the higheſt eſteem. And there ſeems good reaſon for concluding that the author lived in the times of the firſt heathen perſecutions, from many paſſages encouraging faith, and a ſpirit of conſtancy under perſecution.

ESEBON, a name given, by ſome of the chemical writers, to common ſea ſalt.

ESENS, in *Geography*, a town of Germany, in the kingdom of Weſtphalia, and county of Eaſt Friſeland; 24 miles N.N.E. of Emden.

ESFARAIN, a town of Perſia, in the province of Choraſan; 80 miles E. of Aſterabat.

ESGÚEVA, a river of Spain, which runs into the Piſuerga, at Valladolid.

ESGUEYRA, or Esgueria, a town of Portugal, in the province of Beira, containing about 1600 inhabitants; 8 miles S. of Aveiro.

ESH, in *Rural Economy*, a term provincially employed to denote the aſh-tree.

ESHANESS, in *Geography*, a cape on the weſt coaſt of Main-land, the largeſt of the Shetland iſlands. N. lat. 60° 38′. Long. 1° 7′ E. of Edinburgh.

ESHCOL. See Escol.

ESHTAOL, in *Ancient Geography*, a town of Paleſtine, in the tribe of Dan, which belonged firſt to Judah. According to Euſebius it was 10 miles diſtant from Eleutheropolis, towards Nicopolis.

ESHTEMOTH, a city in the ſouth of Judah, which, according to Euſebius, was a large town in the diſtrict of Eleutheropolis, north of that city. It was ceded to the prieſts. 1 Chron. vi. 57.

ESI, in *Geography*, a town of Italy, in the ſtate of the church, and marquiſate of Ancona; 11 miles S.S.W. of Ancona.

ESK, South and North, rivers of Scotland, which deſcend from the Benakinnan mountains on the north border of Angus. The former runs S.E. and E. by Cortachie, Tannadyce, Brechin, and falls into the German ocean below Montroſe, to which town it is navigable from the tide-way in the German ocean. (See Canal). The direction of the latter is E. and S.E. through a narrow valley, till it reaches the ſtrath lying between the Grampians and the ſea. In the lower part of its courſe it forms the common boundary of Angus and Kincardine.

Esk, a river in Cumberland, which is navigable from the Solway firth up to the town of Longton.

ESKARMAKRUN, a town of Perſia, in the province of Chuſiſtan; 90 miles S. of Suſa.

ESKE, a river in the Eaſt Riding of Yorkſhire, which is navigable only from the ſea up to Whitby-bridge. See Canal.

Eske, a river in Cumberland, which is navigable from the ſea near Ravenglaſs to Mulcaſter. Near to Ravenglaſs it is joined by the Irt river.

ESKER, a river of European Turkey, which runs into the Danube; 20 miles W. of Nicopolis.

ESKI-Baba, a town of European Turkey, in Romania; 30 miles S.E. of Adrianople.

ESKIER, a town of Arabia, in the country of Yemen; 60 miles N. of Aden.

ESKIJALFA, a town of Perſian Armenia, in the country of Erivan; 120 miles S. E. of Erivan.

ESKI-HISAR, a town of Aſiatic Turkey, in the province of Natolia; 16 miles W. of Mogla.

ESKI-HISSAR, a town of Aſiatic Turkey, in the province of Natolia, formerly Laodicea, now almoſt a heap of ruins; 8 miles N. of Degnizlu.

ESKIMAUX, or Esquimaux. See Esquimaux and Labrador.

Eskimaux *Bay*, a bay on the ſouth-coaſt of Labrador. N. lat. 51° 30′. W. long 57° 50′.

Eskimaux *Iſlands*, a cluſter of ſmall iſlands in the gulf of St. Lawrence, near the ſouth-coaſt of Labrador. N. lat. 50° 15′. W. long. 63°.

ESKISADRA, a town of European Turker, in the province of Romania; 48 miles E. of Filippopoli.

ESKISHEHR, a town of Aſiatic Turkey, in the province of Natolia, on the river Sakharia; 116 miles S.E. of Conſtantinople. N. lat. 39° 48′. E. long. 32° 58′.

ESLA, a river of Spain, which runs into the Duero, between Zamora and Miranda de Duero.

ESLINGEN, a town of Germany, in the circle of Suabia, which, till the peace of Luneville, was a free imperial city. It now belongs to the king of Wirtemberg, and is ſituated on the Necker, 30 miles N. E. of Tubingen, and 6 miles S. E. of Stutgard.

ESMONA, or Azemona, in *Ancient Geography*, a town of Arabia Petræa, which was one of the ſtations of the Iſraelites in the Deſert. The book of Joſhua aſcribes it to the tribe of Juda, ſo that it is probably the ſame with *Eſem*.

ESMOUTIER, in *Geography*, a ſmall town of France, in the department of the Upper Vienne; 21 miles E. of Limoges.

ESNA, in *Ancient Geography*, a town of Paleſtine, in the tribe of Juda. Joſh. ch. 15.

ESNECY, *Æſnecia, dignitas primogeniti*, in *Law*, a private prerogative, allowed to the eldeſt coparcener, where an eſtate has deſcended to daughters for want of heirs male, to chuſe firſt after the inheritance is divided. Fleta, lib. v. cap. 10. "Jus eſneciæ *is* jus primogenituræ," in which ſenſe it may be extended to the eldeſt ſon, and his iſſue, holding firſt. In the ſtatute of Marlbridge, cap. 9. it is called "initia pars hereditatis."

ESNEH, Esné, or *Aſna*, in *Geography*, one of the moſt important towns in Upper Egypt, ſeated on the left of the Nile, in N. lat. 25°. E. long. 49° 15′. This town is governed by an Arabian prince and by a Cachef, dependent on the Bey of Girgé. The Mahometans have ſeveral moſques here, and the Copts a church, that is ſerved by two prieſts. According to the deſcription of Abulfeda, which correſponds in a great degree to its preſent ſtate, Eſné is remarkable for its public baths and its commerce: it is built on the weſtward of the Nile, between Aſſouan and Cous, but nearer to the latter. The Copts are ſaid to be its founders. The well-cultivated territory abounds in grain and palm-trees. Situated on the edge of a rich country it is ſhaded by groves of orange-trees loaded with fruits and flowers, and immediately ſurrounded with gardens amply ſtocked with fruit-trees. It preſents to view ſeveral ancient monuments conſtructed by the Copts, and ſuperb ruins. This town, formerly called *Latopolis*, revered Minerva and the fiſh *Latus*. (Strabo, l. 17.) It contains within its boundary an antique temple, encloſed on three ſides by thick walls. Six large fluted columns, crowned by a capital, ornamented with the palm leaf, form the façade of it; eighteen others ſupport the roof; which is compoſed of large ſquares of marble; the building is ſurrounded by a frieze, and innumerable hieroglyphics cover its exterior aſpects. Thoſe of the inſide, executed with greater care, mark the progreſs made by the Egyptians in ſculpture. Theſe hieroglyphics contain, among other ſubjects, a zodiac and large figures of men with crocodiles' heads; the capitals, though all different, have a very fine effect; and as an additional proof that the Egyptians borrowed nothing from other people, it is remarked, that they have taken all the ornaments, of which theſe capitals are compoſed, from the productions of their own country, ſuch as the lotus, the palm-tree, the vine, the ruſh, &c. The portico of this temple is repreſented by M. Denon, (Travels in Egypt, vols. 2. and 3.) as the moſt perfect monument of ancient architecture. Denon has given a plan and elevation of this portico, and delineated the varieties of its capitals, and part of the ſculptures on the cieling; but he was ſurpriſed that, after all his reſearch, he could find no repreſentation of the fiſh *latus*, from whoſe name the town was called *Latopolis*. At preſent this temple is ſoiled by the ordure of the cattle kept there by the Turks, who convert the moſt beautiful monuments of ancient Egypt into ſtables. About a league to the weſt of Eſné is another temple, on the walls of which is carved in ſeveral places a woman ſeated, repreſenting an Egyptian deity called "Neith," to whom the ancient Greeks gave the name of Minerva. The columns of this temple, as ſome have conjectured, gave to the Greeks the idea of the Corinthian order; the capitals being ornamented with a foliage very much reſembling the Acanthus. Several animals painted on the cieling have preſerved their colours. To the ſouth of Eſné are ſeen the ruins of a monaſtery founded by St. Helena, and near it the burying place of the martyrs, adorned with tombs crowned by cupolas, ſupported by arcades. The inhabitants of Eſné having revolted againſt the perſecution of Diocleſian, this emperor deſtroyed the town, and put them to the ſword. This place, conſecrated by religion, is become a celebrated pilgrimage among the Copts, who repair hither from the moſt diſtant provinces of the kingdom. In the chain of mountains, which ſtretches to the eaſtward of the Nile, and nearly oppoſite to Eſné, are quarries of a ſoft ſtone, called "Baram," which hardens in the fire, and is uſed in the manufacture of kitchen utenſils. Savary's Letters, &c. vol. ii.

ESO'CHE, from εσω, *within*, and εχω, *to have*, in *Surgery*, a tubercle within the anus.

ESOPUS. See KINGSTON.

ESOTERIC. See EXOTERIC.

ESOX, in *Ichthyology*, a genus of the abdominal kind, diſtinguiſhed by the following eſſential particulars. The head flattiſh above; mouth and throat large; jaws toothed, unequal, the upper one flat, lower punctated; tongue broad, looſe; palate ſmooth; eyes round, moderate ſize, and lateral; noſtrils double, near the eyes; gill-covers large, aperture ample, with from ſeven to twelve rays; body elongated, covered with hard ſcales; above convex, and compreſſed at the ſides; lateral line ſtraight, neareſt the back, and ſcarcely viſible; dorſal and anal fin very ſhort, and generally placed oppoſite.

Species.

LUCIUS. Snout depreſſed; jaws nearly equal. Linn. Fn. Suec. Art. Gen. Rondel. *Brochet*, Bell. *Pike*, Penn. Donov. Brit. Fiſhes.

The pike is an inhabitant of moſt of the lakes of Europe, and the north of Aſia, and alſo of many of the larger rivers in Lapland, Siberia, and countries adjacent. It grows to a conſiderable ſize, thoſe of four or five feet in length not being uncommon in the northern regions, and ſometimes even they attain to the length of eight feet or more. The pike is highly prolific, and from its extreme voracity as well as cunning, is called the wolf, or the fox of fiſhes; it ſubſiſts on fiſhes, on frogs, ſerpents, and other reptiles, and on the young of ſwans and other aquatic fowl, and is reputed ſo undaunted in its attacks that it will even contend with the otter for its prey. This fiſh ſpawns in ſpring between the months of February and May. The colours vary in brightneſs at different ſeaſons; in general the upper part is olivaceous green, with the back nearly black, and the whole ſpotted with yellow, whitiſh, or orange, according to the health of the fiſh. The belly white, and the fins beautifully variegated with vivid colours and ſpots of blackiſh purple. The jaws contain a formidable armament of teeth diſpoſed in longitudinal rows. The longevity of the pike is well known to be very great; but what credit ought to be repoſed in the aſſurances of ſome writers, that it lives to the age of two or three hundred years, muſt remain for others to determine. Their multiplication is immenſe; in the northern parts of Ruſſia, and in Siberia, where they are taken in the greateſt plenty, they conſtitute an article of commercial importance, being prepared by means of ſalting and drying, for exportation.

VIRIDIS. Green; lower jaw longer, ſcales thin. Gmel.

This is regarded by Boſc as a variety only of the common pike, (Eſox lucius,) the accuracy of which opinion appears rather uncertain, as we may perhaps be unacquainted with the ſpecies or fiſh intended by Gmelin; the reference of the latter author to the Acus maxima ſquamoſa viridis for the ſame fiſh is ſuppoſed to be incorrect.

SPHYRÆNA. Dorſal fins two, the firſt ſpinous. Linn. Arted. *Sea pike or Spit-fiſh*, Charlt.

There is ſome remote reſemblance between this fiſh and the common pike, from which among other particulars it is diſtinguiſhed by having the lower jaw advanced, the body more ſlender, the tail furcated, and the back furniſhed with two dorſal fins inſtead of one. The rays of the firſt dorſal fin are ſpinous, and are deſcribed both by Linnæus and Artedi as five in number, but according to Bloch theſe amount to only four. The fiſh is blueiſh above, beneath white; the pectoral, ventral, and anal fins red. It grows to the length of two feet, and inhabits the Atlantic and American ſeas. The fleſh is in eſteem.

The Barracauda pike of Shaw's Gen. Zool. deſcribed after Cateſby, appears very cloſely allied to the preceding, if it be not the ſame; the character "brown, elongated, whitiſh beneath, with two dorſal fins and forked tail," differs from that fiſh only in having the upper part brown inſtead of blueiſh. It is found in the Weſt Indies, and grows to the length of eight or ten feet.

BECUNA. Silvery-blueiſh, marked on each ſide by a row of deep-blue ſpots, with two dorſal fins, and forked tail. Shaw. Gen. Zool. *Sphyræna becuna*, Cepede.

This accords ſo nearly with the Eſox ſphyræna that we cannot ſuppreſs our ſuſpicions of its being the ſame. The only authority on which it is deſcribed is a drawing by Plumier; this, indeed, repreſents a fiſh of ſomewhat more elongated form, in which the ſides are marked with a ſeries of blue ſpots not obſervable in the former. If it prove diſtinct it is certainly very analogous. It is deſcribed as a native of the American ſeas.

AUREO-VIRIDIS. Body golden-green, with two dorſal fins, a ſpine before the firſt; lower jaw longer. *Sphyræna aureo-viridis*, Cepede. *Gold-green pike.*

Deſcribed and figured by Cepede from the drawings of Plumier; the body is deep, as in the ſparus, the head ſharp pointed; ſcales middle ſized; tail forked and lunated. The ſpecies inhabits the American ſeas.

VULPES. Dorſal fin in the middle of the back; the gill membrane three-rayed. Gmel. *Vulpes bahamenſis*, Cateſby. *Fox pike.*

Reſembles the common pike, but is more ſlender in proportion towards the tail, the colour brown above, beneath paler. Native of Carolina and the Weſt Indies.

SYNODUS. Dorſal fin in the middle of the back: gill membrane five-rayed. Gmel. *Synodus*, Cateſby.

Cloſely allied to the former, and inhabits the ſame ſeas, and according to Cepede the Mediterranean alſo. The body is marked with duſky bands; abdomen ſilvery; fins ſtriped with black.

HEPSETUS. Lateral line ſilvery. Gmel. *Argentina pinna dorſali pinnæ ani oppoſita*, Linn. Amœn. Acad. *Piquitinga*, Marcgr. Inhabits America.

MARGINATUS. Dorſal and anal fins oppoſite; lateral line ſilvery; lower jaw ſix times as long as the upper. Forſk. Fr. Arab.

This and the preceding are ſuppoſed to be the ſame. The latter is deſcribed by Forſkal as an inhabitant of the Red ſea; its length about a ſpan and a half; the body linear, tapering each ſide, and covered with broad lax, entire ſcales, the colour brown above, beneath white; the anal fin ſmall, triangular, glaucous, and yellow without; dorſal yellow externally; tail bilobate, the upper lobe pale yellow, the poſterior edge brown.

CHINENSIS. Head ſlender, lower jaw longer; eyes large and protuberant. *Sphyræna chinenſis*, Cepede.

Slightly deſcribed by Cepede from the manuſcripts of Commerſon as a native of the Indian ſeas. The general colour is ſaid to be green with a ſilvery hue, and the ſcales of the middle ſize.

CHILENSIS. Jaws equal; lateral line blue. Molina. *Chili pike.*

Native of the Chileſe ſeas. Length from two to three feet; body round, covered with bony angular deciduous ſcales, above golden, beneath ſilvery; fleſh white, and excellent.

ARGENTEUS. Brown variegated with yellowiſh characters. Gmel. Forſter, &c. *Silver pike.*

Inhabits freſh waters of New Zealand and other iſlands of the ſouthern ocean.

BRASILIENSIS. Lower jaw very long; body ſerpentine. Linn. Muſ. Ad. Fr.

Theſe are ſeveral figures of this fiſh in different authors, moſt of which are defective in one particular or other. Nieuhoff omits the anal and ventral fins, Valentyn and Renard conſtitute two ſpecies of the ſame fiſh; and in other repreſentations the dorſal fin is omitted. Linnæus erroneouſly refers to the Timucu of the Braſilians as being ſynonymous; the fiſh ſo named by theſe people has both the jaws elongated, and ending in a point, and is ſuppoſed to be the ſpecies Belone. Gmelin adopts the ſame miſreference. The length of this fiſh is from twelve to fifteen inches; the upper part of the body green, beneath yellow, and the back marked with about ſix broad and equidiſtant bands of fuſcous. The ſpecies inhabits the Braſils, and is eſteemed a delicacy for the table.

GYMNOCEPHALUS. Jaws equal; gill-covers very obtuſe; head naked. Linn. *Naked-headed pike.*

Native of India, according to Linnæus, who ſpeaks of it as being the ſize of the ſand launce.

MALABARICUS. Two canine teeth in each jaw; gill-membrane with five rays. Bloch.

Found in the rivers of Malabar. The length is about twelve inches; its form ſomewhat reſembling that of the common pike. The colour above greeniſh-blue, beneath yellow; fins yellow; at the baſe purpliſh, and marked with ſeveral diſtinct bands of brown. The lower jaw is rather longer than the upper, and the tail is rounded.

CHIROCENTRUS. Breaſt armed on each ſide by a ſpine over the ventral fin; lower jaw longer. Cepede.

Deſcribed from the manuſcripts of Commerſon. Its form reſembles in ſome reſpects that of the common pike. The ſpine is ſaid to be ſtrong, and ſlightly curved; its length about two-thirds that of the fin, of which it appears to be the firſt ray.

BELONE. Each jaw long and ſubulate. Gmel. *Sea pike, gar-fiſh, or ſea needle*, Penn. Donov. Brit. Fiſhes.

Length from eighteen inches to three or four feet, of a very ſlender eel like form, with long projecting ſnout, the back fine green; belly ſilvery. It is a common ſpecies in all the European ſeas; migrating annually in large ſhoals from the depths of the ocean to the ſhore. They appear on our coaſts in the ſpring, commonly announcing the arrival of the mackarel, but remain with us for a much ſhorter period than that fiſh. They depoſit their ſpawn cloſe to the ſhore among the rocks and ſea weeds, where the young are hatched, and after a certain time retire. We have ſeen the fry of this fiſh on our coaſts during the ſummer months. As an article of food the gar-fiſh is held in far leſs eſtimation than the mackarel, to which its flavour in ſome degree approaches. By many people the fleſh is conſidered unwholeſome, and even poiſonous; ariſing, no doubt, from the ſingular circumſtance of the bone becoming of a fine graſs green colour in boiling. This ſpecies grows to the length of eight feet. Donov. Brit. Fiſhes.

SAURUS. Jaws ſubulate, and ſlighty curving upwards, lower one longeſt; above and beneath ſpurious fins near to the tail. *Maxillis ſubulatis ſuaſcendentibus, inferiore longiore, caudam verſus ſupra infraque pinnulis ſpuriis.* Donov. Brit. Fiſhes. *Saurus*, Rondel. *Skipper*, Ray. *The ſaury*, Penn. &c.

The obſcurity that prevailed reſpecting this curious fiſh till within a very recent period, induced us to enter on the details of its general deſcription with rather more than ordinary minuteneſs: the writer of this article has already treated at ſome length on the Eſox ſaurus in his work on Britiſh fiſhes lately publiſhed, and conceives a repetition of the following obſervations ſubmitted on that occaſion may not prove altogether unacceptable.

Our countryman Ray appears to be the firſt writer who deſcribes this rare and curious ſpecies of eſox as a native of Britain; he ſpeaks of it as a Corniſh fiſh, under the provincial name of ſkipper. Rondeletius and Geſner previouſly mention it as a ſcarce kind among the fiſhes of the Mediterranean. In 1769 the ſame fiſh was again introduced to notice by Mr. Pennant in his tour of Scotland, and afterwards in his Britiſh Zoology, wherein we are informed, that vaſt numbers of them were thrown aſhore on the ſands of Leith, near Edinburgh, after a great ſtorm in November, 17[illegible]8. In the ſummer of 1800 a ſingle ſpecimen was taken near the iſle of Portland, in Dorſetſhire, after a hard ſtorm; an account of which, accompanied with a figure of the fiſh in its natural ſize, is given by the Rev. Mr. Rackett, in the third volume of the Linnæan Tranſactions. "This fiſh (Mr. Rackett obſerves) appears to be rare on the Dorſet coaſt. Of the fiſhermen in this part, only one was acquainted with it, and called it a ſkipper, the name under which, according to Ray, it was known in his time on the coaſt of Cornwall. This writer adds that the ſpecies has not been noticed by Linnæus, Gmelin, nor Bloch; and that Pennant has given a very indifferent figure of it in his Tour in Scotland, and has made uſe of the ſame plate in his Britiſh Zoology." See Linn. Tranſ. 3. p. 60.

It is altogether ſingular that this fiſh has no place in either edition of the Linnæan Syſtema, not even that by Gmelin; it is inſerted by Dr. Turton in his tranſlation on the authority of Pennant. The length of this ſpecies is about eighteen inches: the body of a long and ſlender form; not like that of an eel, as writers deſcribe, but agreeing preciſely with that of the common gar-fiſh (Eſox belone). The ſnout is ſubulate, fine, toothleſs, and curving upwards. The jaws are of unequal length, the lower being longeſt, and bending upwards at the tip, in which reſpect it differs from the figures of Mr. Pennant and Mr. Rackett, in both which the jaws appear ſtraight and of equal length. Neither do the jaws, when cloſed, exhibit that remarkable hiatus or gaping ſhewn in thoſe two repreſentations; there is a kind of flexuoſity in the ſhape of the mouth, when open, which might excite ſuch an idea, but upon gently cloſing it the curvature in the form of one jaw will be found to correſpond with the ſuture of the other; ſo that the character "maxillis medio hiantibus," aſſigned to it, is by no means applicable. Dr. Shaw mentions in the Gen. Zool. that "in a ſpecimen figured in the work of Cepede, the jaws are repreſented upwards, contrary to what has hitherto been obſerved; the ſpecimens figured in the work of Mr. Pennant, as well as that of Rondeletius, and the drawing by Mr. Rackett, have the jaws ſtraight." This is certainly true, and it is therefore to be preſumed that the examples from whence the figures of the latter mentioned writers have been taken muſt have ſuſtained injury, or been miſrepreſented; for it is clear Cepede is right in repreſenting the jaws curving upwards: it is indeed evident, from the comparative ſhortneſs of the jaws in the figure by Pennant and others, they could not be perfect, the beak in the fiſh itſelf being nearly twice the length delineated by either. Dr. Shaw has alſo been apparently miſled to the perſuaſion that the ſkin of this fiſh is reticulated by fine fins decuſſating each other at equal diſtances, which is not by any means the natural appearance of the fiſh, and the figure in the Britiſh Zoology is ſtill more erroneous, as it appears entirely ſmooth, and deſtitute of ſcales.

Some miſunderſtanding ſeems to prevail likewiſe as to the colour of the fiſh. Mr. Pennant deſcribes it as having the back duſky, and the belly bright and ſilvery, in which particulars he is followed by Dr. Shaw, who remarks that the colour of the whole animal is duſky above, and ſilvery beneath, with duſky or blueiſh brown back. This is not, however, correct, the true colour of the back of the fiſh is a moſt lovely azure blue, changeable to green, and gloſſed with purple and yellow, and the lower parts ſilvery. The body has a ſmooth appearance, the ſcales with which it is covered being thin and glabrous: the lower part of the body from the gills to the tail is marked with a longitudinal carina or keel, which terminates at the latter part in a ſomewhat protuberant manner.

The ſpecies may be readily diſtinguiſhed by the pinnules or ſpurious fins on the body near the tail, in which particular it agrees with the ſcomber or mackarel genus; theſe have been variouſly miſrepreſented; in the fiſh itſelf they amount altogether to twelve in number, five of which are diſpoſed above and ſeven beneath; and it is alſo neceſſary to add that they are perfectly detached from each other. The fiſh, in point of flavour, reſembles that of the mackarel.

Osseus. Upper jaw longer; ſcales bony. Linn. *Eſox maxilla ſuperiore cauda quadrata*, Arted.

Native of North America and Aſia, and has been found in Europe. (Donov. Brit. Fiſhes.) The ſpecies is from two to three feet in length, and is covered with rhombic ſcales.

Cepedianus. Snout long, jaws ſpatulate; ſcales bony. *Le piſoſteus ſpatula*, Cepede. *Eſox cepedianus*, Shaw.

The principal difference between the two laſt mentioned fiſhes ſeems to conſiſt in the ſnout being ſhorter in proportion in E. cepedianus than the other. There is likewiſe another pike of the ſame bony ſcale kind, which has the jaws rather ſhorter than either, and bears the name of Leverianus. We are not entirely ſatisfied that the three laſt mentioned differ ſpecifically from each other.

No ſmall degree of uncertainty ſeems to prevail throughout this tribe of fiſhes independently of thoſe laſt adverted to; the ſpecies ſynodus, hepſetus, vulpes, and marginatus, appear to be imperfectly underſtood: barracuda, viridis, and becuna, are perhaps more doubtful, as are alſo chirocentrus, and chinenſis; and it will have been obſerved that the true characters of the ſpecies ſaurus were not till lately aſcertained.

The viper-mouthed pike (Eſox ſtomias), and vipera marina of Cateſby, is diſtinguiſhed by having four of the teeth much larger than the reſt: this is a very extraordinary fiſh, and ought, in our opinion, to conſtitute a new genus.

ESPADACINTA, in *Geography*, a town of Portugal, in the province of Tras-los-Montes, ſituated on the Duero, and borders of Spain; 34 miles S.W. of Miranda de Duero, and 28 N. of Almeida.

ESPAGNAC, John-Baptist-Joseph de Sahuguet-Damarzil, Baron d', in *Biography*, a military writer, was born in the year 1713 at Brive la-Gaillarde. At the age of nineteen he entered the army, and became celebrated for great ſkill and proweſs. In 1742 he was aid-decamp in the war of Bavaria, and was afterwards employed by marſhal Saxe as aid-major general and colonel of a regiment of grenadiers. In 1780 he was raiſed to the rank of lieutenant-general, and died at Paris in 1783. As an author he attained a good ſhare of celebrity by his "Campaigns of the King in 1745—48," which were publiſhed in four octavo volumes. He publiſhed alſo "Eſſays on the Science of War," 3 vols. 8vo. "An Eſſay on the great Operations in War," in 4 vols. 8vo; "A Supplement to the Reveries of Marſhal Saxe," in 2 vols. 8vo. 1773. He likewiſe drew up "The Hiſtory of Marſhal Saxe," in 3 vols. 4to. in which are detailed plans of his battles and marches, together with thoſe particulars of the life of that general, as render it a work of conſiderable intereſt to literary as well as to military men." Nouv. Dict. Hiſt.

Espagnac, in *Geography*, a ſmall town of France, in the department of the Lozere; 12 miles S. of Mende.

ESPAGNE, John d', in *Biography*, a French proteſtant divine in the ſeventeenth century, was born at Dauphiné, and became miniſter of the French church in London, an office which he ſuſtained during the reigns of James I. and Charles I. He publiſhed ſeveral ſmall tracts, which were afterwards collected and publiſhed at Geneva and the Hague, in three and in two volumes 12mo. about the year 1670. He alſo publiſhed a work, which he dedicated to Charles I., entitled "Erreurs Populaires en points Generaux qui concernent l'Intelligence de la Religion." Of this and of ſome other of his pieces Bayle ſpeaks in terms of commendation. Moreri. Bayle.

Espagne, in *Geography*. See Epaigne.

ESPAGNET, John d', in *Biography*, who flouriſhed in the 17th century, was preſident of the parliament of Bourdeaux. As a literary character he publiſhed a work entitled "Enchiridion Phyſicæ Reſtitutæ," which was afterwards

wards tranſlated into French under the title of "La Philoſophie des Anciens retablie en ſa Pureté." This may be regarded as the firſt book that appeared in France, in which there is a complete ſyſtem of phyſics contrary to that of Ariſtotle; though the author pretended that he had merely re-eſtabliſhed the ancient philoſophy. He publiſhed alſo a work concerning the philoſoper's ſtone, entitled "Arcanum Hermeticæ Philoſophiæ Opus." Alſo an old MS. entitled "Le Rozier des Guerres," found at Nerac in the king's cloſet, and attributed, though erroneouſly, to the pen of Lewis XI. To this work he added a treatiſe of his own, upon the education of a prince. In publiſhing the "Rozier des Guerres," he followed the original with the utmoſt exactneſs, becauſe, ſays he, "this little tract ſeemed to me ſo good, that I would not embelliſh or diſguiſe it, but have left it in its native ſimplicity; and though the language of it is not in uſe in this age, yet it may be underſtood, being ſo full of good ſenſe and meaning, that with all its jargon it may ſilence the affected language of the court and bar. I have alſo carefully preſerved the ſpelling, becauſe in adding or diminiſhing a letter, a word is often changed, and of old made new." Bayle.

ESPAIN, Saint, in *Geography*, a ſmall town of France, in the department of Indre and Loire; 15 miles S.E. of Chinon.

ESPALIER Trees, in *Gardening*, are ſuch fruit trees of low growth as are trained to treillages or framed woodworks made for the purpoſe, in ranges, ſo as to conſtitute a ſort of hedge. They are uſually planted in ſingle rows along the borders, on the ſides of the principal walks, in the main diviſions of the garden, affording ſhelter to other plants as well as ornament to ſuch parts.

The ſorts of fruit trees moſtly employed in this way are thoſe of the apple, pear, and plum kinds; but many others may be managed in this method where variety is wanted; as the quince, cherry, almond, apricot, mulberry, and filbert. And it is neceſſary, with a view to beauty and uniformity, to manage them in ſuch a manner as to have them that are nearly of the ſame growth in the ſame range or line of planting.

The ſorts of apples moſt adapted to this uſe are thoſe of the golden and other pippin kinds, the nonpareil, rennet, and ruſſet; but many others may be cultivated in this way.

In the pear kind, the jargonelle, blanquette, bergamot, burre du Roy, &c: the melting pears being always better in this way than thoſe of the breaking kind. On ſtrong moiſt ſoils thoſe grafted on quince ſtocks are the beſt, but on dry ones thoſe on free ſtocks.

Trees intended for this uſe ſhould be grafted or budded within a few inches of the ſurface of the ground, that branches may be thrown out regularly from the bottom upwards, to furniſh and fill the treillage; and the more effectually to accompliſh the purpoſe, the firſt ſhoots from the grafts, &c. ſhould be cut off, or headed down within a few inches of the grafts, in the ſpring ſeaſon, when they have had one year's growth. The branches or ſhoots thus produced, whether the trees are in the nurſery, or planted out as eſpaliers, ſhould, in the latter part of the ſummer, or beginning of autumn, be trained both ways laterally in their advancing growth, to ſtakes put down for the purpoſe, or the eſpalier frames. In this way the trees acquire a proper form, thoſe in the nurſery being thus trained and kept for ſale. A ſecond heading down in the upper branches may likewiſe be practiſed when neceſſary, in order to fill up the middle, and completely cover the frames.

When theſe trees have been thus trained for three or four years in the nurſery-ground, they are generally in a proper ſituation for being planted out as eſpaliers in the borders or other parts along the ſides of the walks in the garden or pleaſure ground, a ſufficient breadth being allowed for the borders according to the ſize or extent of ſuch grounds, as ſix, eight, ten, or more feet.

Beſides this, there is another method ſometimes practiſed in forming eſpalier trees, which is that of, after heading the firſt ſhoots down as above, training the ſide-ſhoots horizontally in the direction of the frames, and the middle one upright, forming the lateral ſhoots, which it throws out horizontally on each ſide; and, if they are not thrown off ſufficiently low, heading the upright one down, by which lateral branches will be ſent off, ſo as to range with regularity at the diſtance of ſix or ſeven inches, one above another, on each ſide, from the bottom to the top. In this way the trees have a very neat appearance.

In planting the trees out, when they are of the apple or pear kind, on dwarf ſtocks, the diſtance in the rows ſhould be fifteen, eighteen, or twenty feet; and when on free ſtocks, not leſs than twenty or thirty; and for free growing trees conſiderably more. For plums, the diſtance ſhould be eighteen feet or more; and for cherries, apricots, almonds, and mulberries, it ſhould never be leſs than fifteen. Conſiderably leſs diſtance will, however, be ſufficient for filberts, eſpecially in the poorer ſorts of ſoil.

When theſe trees have been planted, it is the uſual practice to put ſticks down in a line to train them to for the two or three firſt years; but it has a much neater appearance to have the treillage fixed down to train them to at once.

Frames for this uſe are made in different ways, according to the taſte of the perſon who has them; but the moſt uſual ſorts are thoſe conſtructed of three or four inch ſquare pieces of oak timber for the poſts, with rails of deal carried from poſt to poſt, at the diſtance of every ten or twelve inches from the bottom to the top. Between theſe rails thin upright pieces are again ſometimes fixed at the ſame diſtances, for particular purpoſes. The whole ſhould be well painted over in oil ſome time before the trees are to be trained to it. This laſt is performed either by tying the branches to the trellis by oſier twigs, woollen-yarn, or other ſimilar ſubſtances, or by nailing them in the manner of wall-trees. In whichever way it is done, the greateſt exactneſs and regularity ſhould be obſerved in laying in and directing the ſhoots, that they may have a neat regular appearance. The manner of performing the future pruning and managing of theſe trees will be explained when we come to ſpeak of the nature of pruning in general. See Pruning *of Fruit Trees*.

Theſe ſorts of trees are chiefly advantageous in admitting the branches to produce fruit ſpurs on both ſides, which is not the caſe with wall-trees; in taking up but little room in the garden; in not being ſo injurious to the crops that are near them; in affording fruit of a finer flavour, from the more free admiſſion of air and ſun, and in the fruit not being ſo liable to be blown down and injured as in other caſes.

ESPALION, in *Geography*, a ſmall town of France, in the department of the Aveyron, chief place of a diſtrict of the ſame name, with a population of 2622 inhabitants. It is ſituated on the river Lot, 18 miles N.E. of Rhodez, and has ſome manufactures of coarſe woollen cloth. The canton has a territorial extent of 167½ kiliometres, 12 communes, and a population of 9139 individuals.

As chief place of a diſtrict, Eſpalion has a ſub-prefect, a court of juſtice, and a regiſter office. Corn, wine, and madders, grow in its neighbourhood, and the whole diſtrict contains 9 cantons, 101 communes, and 58,855 inhabitants, on a territorial extent of 1630 kiliometres.

ESPAMISCACK, a lake of Lower Canada; 74 leagues N.E. of Quebec. N. lat 50°. W. long. 68°.

ESPAQUE, a town of Perſia, in the province of Segeſtan; 54 miles S.W. of Kin.

ESPARCET, in *Agriculture*, a name ſometimes given to ſaintfoin. See SAINTFOIN.

ESPARRAGOSA, in *Geography*, a town of Spain, in the province of Eſtremadura; 35 miles E.S.E. of Merida.

ESPARRAGUERA, a town of Spain, in the province of Catalonia; 15 miles N.N.W. of Barcelona.

ESPARZA, a town of Spain, in Navarre; 22 miles E. of Pamplona.—Alſo, a town of North America, in Mexico, and province of Coſta-Rica.

ESPEJA, a town of Spain, in the province of Cordova; 17 miles N.N.E. of Montilla.

ESPELETTE, a ſmall town of France, in the department of the Lower Pyrenées, chief place of a canton in the diſtrict of Bayonne, with a population of 1200 individuals. Its canton has a territorial extent of 237½ kiliometres, 7 communes, and 7861 inhabitants.

ESPEN, ZEGER BERNARD VAN, in *Biography*, was born at Louvain in the year 1646. After going through the uſual courſe of ſtudies at the univerſity, with much credit to his talents and diligence, he was admitted to prieſt's orders in the year 1675, and had, within two years of this time, the degree of doctor of laws conferred upon him. From this period till the year 1702, he lived in the college of pope Adrian VI., where he performed the duties of profeſſor, and applied himſelf to the ſtudy of thoſe works which have rendered his name illuſtrious. He obtained ſo much reſpect by his various writings that he was conſulted from every quarter: by the tribunals of juſtice, by the biſhops, and by ſeveral ſovereign princes. His principal work was entitled "Jus Eccleſiaſticum Univerſum." Beſides this, he is well known for other treatiſes, "De peculiaritate et Simonia;" "De Officiis Canonicorum;" "Tractatus Hiſtorico-Canonicus in Canones;" "De promulgatione Legum Eccleſiaſticarum," and many others, all of which were collected and publiſhed in 4 vols. folio, in 1753, at Paris. When he was in his 65th year, he was deprived of ſight by a cataract, which was not removed for two years; during this time, however, he neither loſt his cheerfulneſs, nor remitted his application. His manner of living was at all times frugal, and very ſimple, his temper was benevolent, modeſt, and humble. He was eminent for piety towards God, and for his candour and good-will towards men. He nevertheleſs had made himſelf enemies, by the integrity and independence of his mind; ſome of whom, to render Eſpen obnoxious to the ruling powers, had forged a treatiſe, containing ſome things very offenſive, in a religious and political point of view, which they attributed to him; but he luckily detected the impoſture, and puniſhed the agents. On other accounts, he met with ſevere and unmerited perſecution, and in one inſtance, after a variety of proceſſes, ſentence was pronounced againſt him, without any declaration reſpecting the definitive judgment of the court. Under theſe circumſtances, believing that it was intended to put him under an arreſt, he withdrew to Maeſtricht, and afterwards to Amersfort, in the province of Utrecht, where he died in 1728, in the 83d year of his age. He left behind him, which was afterwards publiſhed, a learned treatiſe, entitled "Commentarius in Canones Juris Veteris ac Novi," and other diſſertations, which are ſaid to contain diſcuſſions on ſome of the moſt important points in moral philoſophy, as well as the canon and civil laws. Moreri.

ESPENCE, CLAUDE DE, was born at Chalons ſur Marne in the year 1511. He received his education at different colleges in Paris, to the principal of which he was choſen rector at a very early age. When he was about thirty years old, he took his doctor's degree, ſoon after which he was invited by the cardinal of Lorrain to reſide in his houſe, to manage the eccleſiaſtical concerns of which he had the care. In the year 1544 he accompanied the cardinal on an embaſſy to Flanders, to negociate a treaty of peace between Francis I. and the emperor Charles V. He was afterwards ſelected by the king to aſſiſt at the eccleſiaſtical conference, to conſider the queſtions proper to be propoſed for diſcuſſion at the council of Trent; and in 1547 he was deputed by Henry II. to attend the council of Trent, which was then transferred to Bologne. Some years afterwards he was employed in negociating at Rome in favour of the French court, where his talents, as a diplomatic miniſter, produced ſuch an impreſſion in his favour, that the pope, Paul IV. wiſhed to attach him to his intereſts by making him cardinal. He declined the intended honour, and having finiſhed the buſineſs on which he was ſent to Rome, he returned to his native country, where he appeared with high reputation at a meeting of the States at Orleans in the year 1560. In the following year he was appointed a member of the conference at Poiſſy, where he attached himſelf to the Calviniſts, which was highly diſagreeable to the Catholic divines, by whom he was likewiſe ſuſpected of being the author of a treatiſe on Image Worſhip, which occaſioned him ſome trouble with the faculty. After this, he paſſed his life in retirement, devoted to his ſtudies, till he died at Paris in the year 1571. His works are chiefly theological; the moſt important are his "Commentaries on the Epiſtles of St. Paul to Timothy and Titus;" in theſe, ſeveral queſtions relative to hierarchy and eccleſiaſtical diſcipline are diſcuſſed. Moſt of his treatiſes were written in the Latin language, in the knowledge of which he was ſuppoſed to excel his contemporaries. He was one of the moſt learned, judicious, and moderate eccleſiaſtics of his time. He was very converſant in the canons and diſcipline of the church; and not leſs celebrated for his knowledge of profane literature. He was attached to the Catholic religion, but was a decided enemy to every ſpecies of perſecution and intolerance. Moreri.

ESPER, JOHN FREDERIC, was born at Droſſenfeld, in Bayreuth, in 1732. He ſtudied very diligently at Erlangen, where he applied himſelf chiefly to theological purſuits, but at the ſame time made himſelf well acquainted with natural hiſtory and botany, of which he afterwards became a teacher. He died of a fever in July 1781, leaving behind him a conſiderable reputation as a naturaliſt, particularly in that department which relates to the zoolites in the principality of Bayreuth. In this place are a number of large ſubterranean caverns, partly inſulated, and partly connected with each other, which contain immenſe numbers of bones of various animals, thrown together in heaps to a conſiderable height, and covered with the earth ariſing from decompoſed animal bodies. The entrance to theſe caverns is highly pictureſque, but almoſt as ſoon as a perſon enters them he is ſurrounded by darkneſs, and the paſſage becomes ſtill more difficult and narrow, till the eye at laſt is ſtruck by the immenſe extent of an awful arch, which on every ſide preſents fiſſures and clefts, ſtrewed with the fragments of once living bodies, which excite the idea of a repoſitory of the dead. With the aid of an ingenious apothecary of Erlangen, Eſper undertook an examination and deſcription of theſe curioſities, and publiſhed the reſult of his labours under the following title; "An accurate Deſcription of the Zoolites of Unknown Animals, &c." This was publiſhed at Nuremberg, in the year 1774, in folio, with fourteen illuminated plates. Eſper was author likewiſe of various papers in the Tranſactions of the Friendly Society of the Searchers into Nature: and he wrote an account of "A Method of determining the Orbits of Comets, and other Celeſtial Bodies without Inſtruments, or Mathematical Calculations." Gen. Biog.

ESPERAZA, in *Geography*, a town of France, in the department of the Aude, and diſtrict of Quillan; 2½ leagues S. of Limoux.

ESPERNAY. See EPERNAY.

ESPERNON, a ſmall town of France, in the department of Eure and Loire, on the river Gueſle; 15 miles N.E. of Chartres, and 6 miles E. of Maintenon.

ESPESEL, a town of France, in the department of the Aude, and diſtrict of Quillan; 2½ leagues S.W. of Quillan.

ESPHLASIS, (from εσφλαομαι, *to recede inwards*,) in *Surgery*, a receſſion of a part of the body inwards, in conſequence of ſome violent outward force.

ESPIERRE, a town of Savoy, in the county of Maurienne, on the river Arc; 3½ miles S. of Argentina.

ESPIERS, in *Geography*, a town of Flanders; 8 miles N. of Tournay.

ESPINAL. See EPINAL.

ESPINAR, a town of Spain, in Old Caſtile; 18 miles S.S.W. of Segovia.

ESPINHAL, a town of Portugal, in the province of Beira; 18 miles S E. of Coimbra.

ESPINOSA DE LOS MONTEROS, a ſmall town of Spain, in Old Caſtile; ſituated in a pleaſant valley, watered by the river Trueva, among the mountains of Burgos, about 15 leagues N.W. of Miranda, in the north corner of the province.

ESPINOSA, a town of Spain, in New Caſtile; 44 miles S.W. of Toledo.

ESPIRITU SANTO, the largeſt and moſt weſterly of the New Hebrides iſlands, in the South Pacific ocean, about 57 miles in length, and 30 in breadth.—Alſo, a province of Braſil, which is chiefly productive of ſugar.—Alſo, a town of Braſil, ſeated in a fertile country on the ſea-coaſt, with a ſmall caſtle and harbour. S. lat. 20° 10′. W. long. 41°.—Alſo, a river of Braſil, which runs into the Atlantic.—Alſo, a town on the ſouth coaſt of the iſland of Cuba; 55 miles S. W. of Bayamo.—Alſo, a bay on the weſt coaſt of Eaſt Florida. N. lat. 27° 36′. W. long. 82° 54′. It has a good harbour and ſafe anchorage; but the land about the ſea-coaſt is very low. Several low, ſandy iſlands and marſhes, covered with Mangrove buſhes, lie before the main land. This bay abounds in the ſummer with fiſh, which may be taken with a ſeine, in quantity ſufficient to load a ſhip, if the climate would admit of curing them, in a few days.—Alſo, a lake towards the extremity of the peninſula of Eaſt Florida, ſouth from the chain of lakes which communicate with St. John's river.

ESPIRITU *Santo, Iſlas del*, iſlands ſituated on the S. W. of Providence in the Weſt Indies. See ANDROS *iſlands*.

ESPLANADE, in *Fortification*, called alſo the glacis; a part which ſerves the counterſcarp, or covert way, for a parapet; being a declivity, or ſlope of earth, commencing from the top of the counterſcarp, and loſing itſelf, inſenſibly, in the level of the champagne.

ESPLANADE alſo ſignifies the ground which has been levelled from the glacis of the counterſcarp to the firſt houſes; or the vacant ſpace between the works and the houſes of the town.

The term is alſo applied, in the general, to any piece of ground which is rendered flat, or level, and which before had ſome eminence that incommoded the place.

ESPLEES, EXPLETIÆ, from *expleo*, in *Law*, the products which ground or land, &c. yield; as the hay of the meadows, the herbage of the paſture, corn of the arable, rents, ſervices, &c. and of an advowſon, the taking of tithes in groſs by the parſon; of wood, the felling of wood; of an orchard, the fruit growing there; of a mill, the taking of toll, &c. Theſe and ſuch like iſſues are termed eſplees. And it is obſerved, that in a writ of right of land, advowſon, &c. the demandant ought to allege in his count, that he or his anceſtors took the eſplees of the thing in demand; otherwiſe the pleading will not be good.

Sometimes this word hath been applied to the farm, or land, &c. themſelves. "Dominus E. habebit omnia expletias & proficua de corona emergentia." Plac. Parl. 30 Ed. I.

ESPOSENDA, in *Geography*, a town of Spain, in the province of Galicia; 12 miles S. W. of Orenſe.

ESPOSENDE, a ſmall port town of Portugal, in the province of Entre Minho, at the mouth of the Cavado, three leagues S. of Viana. Its ſhallow harbour is ſlightly protected by a fort, 22 miles N. of Oporto.

ESPRIT, JAMES, in *Biography*, was born at Beſiers in the year 1611. Having paſſed through his initiatory ſtudies, to which he had applied himſelf with great diligence, he was introduced to the duke de la Rochefoucault, who brought him acquainted with the chancellor Seguier, who not only allowed him a penſion from his own private purſe, but procured for him a penſion of two thouſand livres, on an abbey and a brevet of counſellor of ſtate. Through ſome ſecret enemies he incurred the diſpleaſure of the chancellor, and withdrew to the ſeminary of St. Magloire, where he became acquainted with the prince of Conti, and at that time had ſerious thoughts of entering the church. This prince was ſo charmed with the converſation of M. Eſprit, that he gave him handſome apartments in his own hotel, and a penſion of a thouſand crowns. In a ſhort time afterwards Eſprit gave up all thoughts of the eccleſiaſtical life, and determined to marry. On this occaſion he received ſome handſome preſents from the prince, to whom he became ſo much attached that he followed him, in 1766, to his government of Languedoc, and became his moſt confidential friend and adviſer. After the death of his patron, he devoted the whole of his time to the education of that prince's children. He himſelf died at the place where he was born in 1678. As a literary man he left behind him "Paraphraſes on ſome of the Pſalms;" and a treatiſe, entitled "La Fauſſetè des Vertus humain," in two volumes, which was publiſhed the ſame year in which he died, and which was intended as a commentary on the maxims of his firſt patron the duke de la Rochefoucault, to ſhew the fallacy of the virtues that are merely human, and the reality of Chriſtian virtues. By the abbè Olivet and others he is ſuppoſed to have been the tranſlator of Pliny's panegyric on Trajan. Eſprit was a member of the French academy, and in its infancy was conſidered as one of its ſhining ornaments. Moreri.

ESPRIT, *Saint*, in *Geography*, a ſmall town of France, in the department of the Landes, chief place of a canton in the diſtrict of Dax, with only 589 inhabitants. Its canton has a population of 10,161 individuals, diſperſed in eight communes, on a territorial extent of 147½ kiliometres.

ESPOUSALS, SPONSALIA, in *Law*, a contract or mutual promiſe between a man and a woman to marry each other. Marriage or matrimony is ſaid to be an eſpouſal de preſenti.

ESPRONCEDA, in *Geography*, a town of Spain, in Navarre; 11 miles W.S.W. of Eſtella.

ESQUADRILLE. See QUADRILLE.

ESQUADRON. See SQUADRON.

ESQUERDES, in *Geography*, a town of France, in the department of the ſtraits of Calais, and diſtrict of St. Omer; one league S. of St. Omer.

ESQUIAVINE, in the *Manege*, an old French word ſignifying a long and ſevere chaſtiſement of a horſe in training him.

ESQUILIÆ, or ESQUILINUS MONS, in *Ancient Geography*, one of the ſeven mountains on which Rome was ſeated, where was anciently one of the gates of the city, now the gate of St. Laurence, to whoſe magnificent church it leads. This gate ſeems to have been anciently called "Libitinenſis," on account of the dead bodies that were carried through it, in order to their being interred in the "Campus Eſquilinus," which was the general burying-place of the common people. The name of Eſquilinus was varied, for facility of pronunciation, from Exquilinus, a corruption of Excubinus, *ab Excubiis*, from the watch that Romulus kept in this place. It was taken in by Servius Tullius, who had his royal ſeat upon this hill. Varro will have the Eſquiliæ to be two hills. To the eaſt, it has the city walls; to the ſouth, the via Labicana; to the weſt, the valley lying between Mons Cœlius and Mons Palatinus; to the north, Mons Viminalis; and is in compaſs between three and four miles. It is now called "Il Monte de Santa Maria Maggiore." One of the 14 regions or wards, inſtituted by Auguſtus, was denominated "Eſquilina." It contained 15 ſtreets, eight luci, ſix temples, five ædes, 75 public baths, 18 granaries, 22 mills, and 180 great houſes; and its circuit was 15,950 feet.

ESQUIMAUX, the inhabitants of the coaſts of Labrador and Hudſon's bay, who differ, in ſeveral characteriſtic marks, from the inland inhabitants of North America. That the Greenlanders and the Eſquimaux agree in every circumſtance of cuſtoms, and manners, and language, which are demonſtrations of an original identity of nation, was diſcovered near half a century ago. Crantz, in his "Hiſtory of Greenland," (vol. i. p. 262.) informs us, that the Moravian brethren, who, with the conſent and furtherance of ſir Hugh Palliſer, then governor of Newfoundland, viſited the Eſquimaux, or the Labrador coaſt, found that their language, and that of the Greenlanders, do not differ ſo much as that of the high and low Dutch. Mr. Hearne, in 1772, traced this unhappy race farther back, towards that part of the globe, from whence they had originally coaſted along in their ſkin-boats, having met with ſome of them at the mouth of the Copper-mine river, in the latitude of 72°, and near 500 leagues farther weſt than Pickerſgill's moſt weſterly ſtation in Davis's ſtrait. Their being the ſame tribe, who now actually inhabit the iſlands and coaſts on the weſt ſide of North America, oppoſite to Kamtſchatka, is a diſcovery, the completion of which was reſerved for captain Cook. The reader of his third voyage will find them at Norton ſound, and at Oonaleſhka, and Prince William's ſound; that is, near 1500 leagues diſtant from their ſtations in Greenland, and on the Labrador coaſt. And leſt ſimilitude of manners ſhould be thought to deceive us, a table exhibiting proofs of affinity of language, drawn up by captain Cook and inſerted in the appendix to the work juſt cited, will remove every doubt from the mind of the moſt ſcrupulous inquirer after truth. See *New* BRITAIN and LABRADOR.

ESQUIMAUX *Bay*. See ESKIMAUX.

ESQUINANCY, in *Medicine*, from the French *eſquinancie*; whence our more common term *quinſy*. See CYNANCHE.

ESQUIRE, a title of diſtinction, next below that of knight, and above that of a ſimple gentleman.

The origin, both of the name, and the thing, eſquire, is very obſcure. The Engliſh denomination is confeſſedly borrowed from the French, *eſcuyer*; and that from the Latin *ſcutum*, ſhield, as ſome will have it; or, as others, from *ſcutarius*, or *ſcutiger*, ſhield-bearer; or from *ſcuria*, ſtable; or from *equiſo*, groom. So many different opinions of the formation of the word have given riſe to as many about the primitive office of eſquires; unleſs, perhaps, the latter hath given occaſion to the former. Paſquier, in his Recherches, liv. ii. chap. 15. maintains the title of eſquire, *eſcuyer*, *ſcutarius*, to be very ancient. From the time of the decleſion of the Roman empire, he obſerves, there were two extraordinary kinds of ſoldiery in the Roman army: the one called *gentiles*, and the other *ſcutarii*.

Ammian. Marcellin. lib. xiv. cap. 7. and lib. xvi. cap. 4. ſpeaks of theſe *ſcutarii* as men of redoubted prowefs, and even deemed invincible: it is added, that Julian the Apoſtate ſet a mighty value on thoſe troops, when he was among the Gauls; and hence, probably, it was, that the Gauls, or perhaps only the Franks, finding the braveſt among the Roman forces were called *gentiles*, and *ſcutarii*, gave the like names to the boldeſt and braveſt among themſelves; ſuch, according to that curious antiquary, is the original of eſquires.

Eſquire, however, afterwards came to be uſed in a ſomewhat different ſenſe; *viz.* for a gentleman who attended a knight in the wars, and on other military occaſions; bearing his ſhield, *ſcutum*, before him (whence he was called *ſcutarius*, *ſcutiger*, or *ſcutifer*), as alſo his lance, and other weapons; whence his other Latin appellation, uſual among us, *armiger*, q. d. *armour-bearer*. And hence likewiſe it is, that, in all our ancient romances, the hero is conſtantly attended by a gentle and truſty *'ſquire*.

After all, the moſt probable derivation of *eſcuyer* is not from *eſcu*, *ſcutum*, as is the common opinion; but from *equus*, horſe; the primitive eſquires being no other than what the Latins call *equiſons*, who had the care and intendance of the equerries, or ſtables, only.

Be this as it will, the title eſquire, *armiger*, as now eſtabliſhed among us, is next below that of knight, *eques*. They who bear this title are all younger ſons of noblemen, and the eldeſt ſons of ſuch younger ſons; the eldeſt ſons of knights, and their eldeſt ſons ſucceſſively; both which ſpecies of eſquires ſir Henry Spelman entitles *armigeri natalitii*; the four eſquires of the king's body, now diſuſed, and eſquires created by the king, by putting about their necks a collar of SS's, and beſtowing on them a pair of ſilver ſpurs, letters patent, or other inveſtiture, and their eldeſt ſons. Laſtly, divers others, in the ſuperior public offices, are reputed eſquires, or equal to eſquires; as ſheriffs of counties, ſerjeants at law, juſtices of peace, mayors of towns, counſellors at law, lieutenant-colonels, majors, captains, &c. during the time of their commiſſion. Laſtly, the heads of ſome ancient families are likewiſe eſquires by preſcription. To theſe may be added the eſquires of knights of the Bath, each of whom conſtitutes three at his inſtallation; and all foreign, nay Iriſh peers; for not only theſe, but the eldeſt ſons of peers of Great Britain, though frequently titular lords, are only eſquires by the law, and muſt be ſo named in all legal proceedings. See GENTLEMAN.

ESQUISSE, in the French *Painting*, a term ſignifying the firſt ſlight ſketch or draught of a picture; the firſt thought of a deſign drawn haſtily with a crayon; or in colours, on paper, canvas, or the like, in order to be finiſhed, and painted, or engraven afterwards.

He had not the trouble of making a finiſhed and correct deſign, but went to work upon the eſquiſſe.

The word is formed of the Italian *ſchizzo*, a ſplaſh; becauſe an eſquiſſe of a painting only repreſents, as it were, ſplaſhes, or dabs, of colours.

ESQUIVO. See Essequibo.

ESRAKITES. See Eschrakites.

ESS, in *Agriculture*, a term made uſe of in ſome places to ſignify aſhes.

ESSA, in *Ancient Geography*, a town of Paleſtine, on the other ſide of Jordan, according to Joſephus, who ſays that it was taken by Alexander, king of the Jews.

ESSACHORDO. See Hexachord.

ESSÆANS. See Esseni.

ESSAORE, in *Geography*, a town of Egypt; three miles S.S.E. of Achmim.

ESSARS, Les, a town of France, in the department of La Vendée, and diſtrict of La Roche-ſur-Yon; 3 leagues N.E. of La Roche.

ESSART, or Assart. See Assart.

Du-Cange derives the word from ſome of the barbarous Latin words, exartus, exartum, eſſartum, aſſartum, ſartum, and ſartus; which all ſignify a foreſt cut down, or dug up; though Spelman chooſes to deduce it from the Latin *exertum*, torn up, or unrooted. Others from *ſarrire*, to weed; and others, laſtly, from *exaro*, I plow; whence *exarare*; and, by contraction, *exartum*. In our ancient law-books, "exartum facere in ſylva," is to eſſart a place in a foreſt. To eſſart, is to grub up, or extirpate buſhes, trees, old roots, ſtumps, or the like; in order to fit the ground for tillage.

Essarts, *Les*, in *Geography*, a ſmall town of France, in the department of La Vendée, chief place of a canton in the diſtrict of Montaign, with a population of 2089 individuals, 24 miles W. of Mauléon. Its canton contains 9 communes, and 9043 inhabitants, on a territorial extent of 242½ kiliometres.

ESSATUM, a word uſed by ſome of the chemical writers to expreſs the medicinal power or ſanative property reſiding in ſimple medicines.

ESSAY, a trial, or experiment, to prove whether a thing be of the requiſite quality or goodneſs.

The word is French, *eſſai*; which ſome authors derive farther from the Latin *examen*.

Essay is alſo uſed for an attempt, or tentative, to learn whether or not a thing will ſucceed.

Eſſays of machines ſhould be made in large; it is not enough that they ſucceed in little.

Essay, in *Monaſteries*, is particularly uſed for a trial which a perſon makes of the monaſtic life, in a ſecular habit.

This eſſay is of one, two, and, in ſome monaſteries, of three months. The eſſay is not reckoned in the noviciate. See Probation.

Essay, or *Aſſay*, or ſimply *Say*, in *Coinage*. See Assay.

Essay, in matters of learning, is a peculiar kind of compoſition; whoſe character is to be free, eaſy, and natural; not tied to ſtrict order, or method, nor worked up, and finiſhed like a formal ſyſtem.

The matter of an eſſay is ſuppoſed to conſiſt principally of ſudden and occaſional reflections, which are to be wrote much at the rate, and in the manner, a man thinks; ſometimes leaving the ſubject, and then returning again, as the thoughts happen to ariſe in the mind.

At leaſt, this has hitherto been the practice; and Montagne, who has acquired no ſmall reputation by this way of writing, ſeldom keeps many lines to the ſubject he propoſes; though it is our opinion, that lord Bacon, in many of his works, is a better pattern in the eſſay kind. Mr. Locke, however, and a few other authors, uſe eſſay in a ſtricter ſenſe: the Eſſay of Human Underſtanding, every body knows, is a regular, artful, and laboured work; though perhaps ſo called to guard againſt too ſevere ſtrictures, by pleading the title.

Essay-*hatch*, is the miners term for a little trench or hole, which they dig to ſearch for ſhoad, or ore. See Tin.

Essay-*maſter*. See Mint, and Assay.

ESSE, in the *School Philoſophy*, is uſed in the ſame ſenſe with eſſence; principally for that which is actual, or actually exiſting.

The word is pure Latin; being the infinitive of the verb *ſum*, I am; whence *eſſe*, to be.

From eſſe ariſes *eſſatum*, a barbarous term, now almoſt obſolete, ſignifying that which is ended with eſſence, or nature; or affected with the virtue, or efficacy, of another. Some diſtinguiſh eſſe into *real* and *intentional*; and, again, into *eſſatum* and *volitum*.

ESSEDARIUS, among the Romans, a gladiator, who fought in a car or chariot. See Hiſt. Acad. Inſcrip. vol. ii. p. 376. ſeq.

ESSEL, or Ebstel, in *Geography*, a town of Germany, in the circle of Weſtphalia, and county of Verden; 2 miles N. of Verden.

ESSEN, a ſmall town of Germany, in the circle of Weſtphalia, remarkable for its manufactures, chiefly of ſwords and fire arms; but more particularly for a rich abbey, which, until the peace of Luneville in 1801, was a free imperial abbey. It was ſecularized, and its poſſeſſions, together with the town and its territory, were given to Pruſſia as an indemnity for her loſſes on the right ſhore of the Rhine. After the peace of Tilſit in 1807, when Pruſſia loſt all her dominions beyond the Elbe, Eſſen was added to the grand duchy of Berg and Cleves, which now belongs to the eldeſt ſon of the king of Holland. There are other towns of this name in the circle of Weſtphalia.

ESSENBACK, a town of Denmark, in Jutland; 4 miles from Randers.

ESSENBERG, a town of Germany, in the circle of Weſtphalia, and county of Meurs, near the Rhine; 3 miles E. of Meurs.

ESSENCE, a term much uſed among the ſchoolmen; and denoting what the Platoniſts called the idea of a ſpecies. The word *eſſentia* is ſaid to have been made by Cicero; but his authority could not give it currency, until long after his time. It came at laſt to be uſed, and the ſchoolmen fell into much the ſame opinions concerning eſſences, as the Platoniſts held concerning ideas. The eſſences of things were held by many to be uncreated, eternal, and immutable. Mr. Locke diſtinguiſhes two kinds of eſſence, the real and the nominal. By the former he means the conſtitution of an individual, which makes it to be what it is. This eſſence moſt begin and end with the individual to which it belongs. It is not therefore a Platonic idea. But the latter or nominal eſſence, ſo called by Mr. Locke, is the conſtitution of a ſpecies, or that which makes an individual to be of ſuch a ſpecies; and this is nothing but that combination of attributes which is ſignified by the name of the ſpecies, and which we conceive without regard to exiſtence. The eſſence of a ſpecies is, therefore, what the Platoniſts called the idea of the ſpecies. The nominal eſſence depends on the real eſſence; thus, the nominal eſſence of gold, is that complex idea which the word gold repreſents; *e. gr.* a body, yellow, heavy, malleable, fuſible, and fixed; but its real eſſence is the conſtitution of its inſenſible parts, on which thoſe qualities, and all its other properties depend; which is wholly unknown to us.

In philoſophy, the eſſence of a thing is defined to be, that whereby a thing is diſtinguiſhed from every other thing. The Carteſians hold the eſſence of matter to conſiſt in extenſion; and, on that principle, deny that there is any ſuch thing as mere ſpace, or vacuity; but the hypotheſis is falſe, as will be ſhewn under the articles MATTER, SPACE, VACUITY, PLENUM, &c.

Gaſſendus, and moſt of the corpuſcular philoſophers, hold the eſſence of matter to conſiſt in ſolidity, or impenetrability, reſiſtance, or, more adequately, in a ſolid impenetrability reſiſting the touch; which it muſt be allowed, of all the properties of matter, ſeems to have the faireſt title to it.

The ſchool philoſophers give us two ſignifications of the word eſſence; the firſt denotes the whole eſſential perfection of a being, and, conſequently, its entity, with all its intrinſic, or eſſential, and neceſſary attributes, taken together; in which ſenſe, eſſence may be defined to be, all that whereby a thing is, and what it is. In which caſe the eſſence of a thing is to the thing itſelf, what humanity, *e. gr.* is to man.

The ſecond ſignification of eſſence is, that whereby it denotes the principal, and moſt intimate, of all the attributes of a thing; or that which agrees to every ſuch thing, and ſuch alone, and that always, and in ſuch manner, as that the mind, with all its attention, cannot perceive any thing prior thereto; by which, eſſence is diſtinguiſhed from the eſſential attributes, *i. e.* from ſuch as flow from its eſſence, or firſt attribute. Thus, the eſſence of the human mind is commonly ſuppoſed to conſiſt in the power of thinking; becauſe all its other perfections ſeem to pre-ſuppoſe this; but this pre-ſuppoſes none. And thus the powers of underſtanding, doubting, aſſenting, willing, &c. do all flow from the power of thinking; and cannot exiſt without it, though this may without any of them.

It muſt be allowed, however, that the eſſential properties of a thing do ſo cloſely cohere, nay, and inhere, in the eſſence itſelf, that it is ſcarcely poſſible to diſtinguiſh the one from the other. Hence, what ſome urge, that, ſetting aſide all the attributes and properties of a thing, and what remains is its eſſence, is a mere chimera. For ſet aſide, *e. gr.* from the mind, the powers of underſtanding and willing, with the reſt of its attributes, and what will there remain to call its eſſence?

It is greatly diſputed, in the ſchools, whether the eſſences of created things be eternal? or whether the eſſences, as well as their exiſtence, had their origin in time? The Carteſians hold, that the eſſences of things depend abſolutely on the free concurring will of God.

ESSENCE, *Eſſential oil, Eſſential ſalt.* The eſſence of a vegetable, according to the old chemiſts, was, that one of its proximate elements, in which reſided the quality of taſte or odour, which peculiarly diſtinguiſhed it from other vegetables, and rendered it eſpecially applicable to pharmaceutical purpoſes. Thus the fragrance of orange peel, of pepper-mint, of cinnamon, was found by experience to be ſeparable from the other parts of the vegetable, by means of diſtillation, &c.; the reſult of this proceſs was a ſmall portion of highly fragrant oil, in which was contained the entire odour that had been naturally diſperſed through the whole maſs: hence the oil thus procured obtained the name of "eſſential oil." Again, moſt ſour vegetables, as ſorrel, lemons, &c. owe this quality to the preſence of an acid, which, when ſeparated from the other vegetable principles, aſſumes a cryſtalline appearance, and was known by the name of their eſſential ſalt. The ſame appellation was alſo given to all thoſe vegetable principles which, when pure, are capable of cryſtallizing, whether they were acid to the taſte or not. Thus ſugar was ranked among the eſſential ſalts. The term, however, is at preſent obſolete. Eſſential oil ſtill retains its place in chemical nomenclature, and we refer the reader to the article OILS, *eſſential*, for a particular account of their ſpecies and properties.

ESSENCE *of Roſes.* See ROSES.

ESSENCE, *Ward's.* See WARD'S *Medicines.*

ESSENCE *of Wine*, a term uſed by Paracelſus, and ſome of the German chemiſts ſince his time, to expreſs what is called ſometimes the philoſophical ſpirit of wine, or the ſpirit of wine of the ancients. It is not a diſtilled ſpirit like what we call ſpirit of wine, but approaches more to what Stahl has greatly recommended to the world, under the name of concentrated wine, or wine whoſe ſtrength has been reduced to a ſmaller compaſs, by ſeparating its aqueous parts only by freezing. Stahl recommends the immediately expoſing of wine to the froſty air on this occaſion; but the proceſs ordered by Paracelſus for the preparation of this liquor is more tedious. He orders that the fineſt and beſt flavoured wine be choſen; that it be put into a glaſs, filling it up three parts in four: and the neck being then ſealed hermetically, it is to be put into horſe-dung for three months, and then expoſed to the froſty air for a month, after which the ice is to be thrown away, and the liquid part, which is the eſſence, preſerved. Shaw's Chemical Eſſays.

ESSENDO *Quietum de Tollonio*, in *Law*, a writ to be quit of toll, and lies for citizens and burgeſſes of any city or town that by charter or preſcription ought to be exempted from toll, where the ſame is exempted of them. Reg. Orig. 258.

ESSENEUX, in *Geography*, a town of the Netherlands, in the duchy of Limburg, ſituated on the Ourt; 9 miles S. E. of Liege.

ESSENI, ESSENES, or *Eſſæans*, an ancient ſect among the Jews.

As to the etymology of the name, critics have been much divided. Philo derives it from οσιος, *holy*; Epiphanius from ישי, *Jiſhai, Jeſſe*, the father of David; Salmaſius from a city called *Eſſa*, mentioned by Joſephus; whence he apprehends the ſect firſt ſprung; Godwin derives it from the Syriac word אסא, *aſa*, which ſignifies *to heal*; becauſe Philo calls one branch of the Eſſenes Therapeutæ; and Serrarius enumerates at leaſt a dozen different etymologies. Philo in Tract. Omnis probus Liber. Oper. p. 678. Colon. Allobr. 1613. Epiphan. Hæreſ. xix. lib. i. Salmaſ. Plin. exercit. in Solin. cap. 35. Serrar. Trihæres. Jud. lib. iii. cap. 1. p. 106. 110. edit. Trigland. 1703. The principal ancient writers, who give any conſiderable account of the Eſſenes, are Joſephus, Philo, and Pliny. Joſ. de Bell. Jud. lib. ii. cap. i. cap. 8. & 12. and Antiq. lib. cxiii. cap. 9. 13. 19. lib. xviii. cap. 1. & cap. 2. & alibi. Philo, ubi ſupra, & De Vita contemplativa, p. 688. ed. col. Allobr.

As to the origin of this ſect, Pliny aſſerts, without mentioning his authority, that it had ſubſiſted for ſeveral thouſand years. The moſt probable opinion is, that this ſect was formed by Jewiſh exiles, a little before the time of the Maccabees, who were forced to fly from the perſecution of their enemies into caves and deſerts. The firſt Eſſenes we read of are mentioned in the fourth book of Maccabees, under the name of Haſdanim, and by Joſephus; both which accounts agree that they were already ſettled in Judæa, in the time of Jonathan, the brother and ſucceſſor of Judas Maccabæus, about a hundred and fifty years before Chriſt. Joſephus ſtates that their number in Judæa was about four thouſand, meaning, as Dr. Lardner (Works, v. i. p. 128.) ſuggeſts, thoſe of them, that entirely rejected marriage. Philo ſays, that in Syria and Paleſtine there were about 4000 of them, but he makes the number in Egypt much greater. Philo ſays, that they ſacrificed no living creatures, and that they ſhunned cities. Joſephus ſays that they ſent preſents to the temple, but offered no ſacrifice there. They ſeem therefore not to have expoſed themſelves much to public view, nor would they admit a man of another ſect into the apartments in which they lived. Some have expreſſed their ſurpriſe, that no mention ſhould be made of this ſect in the New Teſtament. This proceeded, as ſome imagine, from their retired mode of living, by reaſon of which they never came under our Saviour's obſervation, as the Phariſees and Sadducees often did. Others ſuppoſe, that, being very honeſt and ſincere, without guile or hypocriſy, they gave no reaſon for that reproof and cenſure, which the others very juſtly merited. It ſhould be conſidered that it was the deſign of the evangeliſts to write the hiſtory of our Saviour's miniſtry, and not that of the Jewiſh ſects. Prideaux obſerves, that almoſt all that is peculiar in this ſect is condemned by Chriſt and his apoſtles. Prid. Conn. vol. iii. p. 384. However, it has been ſuppoſed, that they are referred to by the apoſtle Paul in his epiſtle to the Coloſſians, ch. ii. 18. 21. 23.

Joſephus, making mention of the ſeveral ſects among his countrymen, diſtinguiſhes three; *viz.* the Phariſees, Sadducees, and Eſſeni; which laſt he prefers to the two former, as to their manner of life. He aſſures us, farther, that they were Jews, by original; from which it ſhould appear, that St. Epiphanius was miſtaken in ranking them among the Samaritans.

In effect, the Eſſeni appear to have been true Pythagorean philoſophers, in every thing that related to their manner of living; for they greatly affected ſolitude and retirement; and avoided all converſation with women, to devote themſelves more entirely to the contemplative life. Grotius will have the Eſſeni the ſame with the ancient חסדים, *Haſidim*, or *Haſidæi*; thus called, according to Philo, from their ſingular piety, humility, and devotion. Among theſe, Gale obſerves, it was, that the Hebrew philoſophers chiefly flouriſhed. Porphyry is very prolix in his praiſes of the Eſſeni: *Εισι τοινυν οι Εσσαιοι Ιȣδαιοι μεν το γενος φιλαλληλον*, &c. He repreſents them as deſpiſers of pleaſures, riches, glory, and delicacy; and ſtrenuous retainers to continency, auſterity, ſtudy, &c. He adds, they decline marriages, and adopt and educate other people's children in the principles of religion and philoſophy; they are all on a level, hold every thing in common, neither buy nor ſell, &c. By long habit, they arrived at ſuch a degree of patience, that Porphyry aſſures us, flames and tortures had not the leaſt effect on them. They ſcorned to intreat their tormentors; nor ever ſhed a tear; but would ſmile under all their agonies, &c. As to their learning, Philo Judæus, in his treatiſe, That every good Man is free, tells us, that they deſpiſed logic, as uſeleſs to the acquiring of virtue; phyſics they left to the ſophiſts and diſputants, as judging it to tranſcend the human faculties; and applied themſelves wholly to morality. Porph. de Abſtin. lib. iv. § 11. ſeq. Gale Philoſ. Gener. lib. i. cap. 1. § 11.

Both Joſephus and Philo give a ſurpriſing account of their auſtere way of life, which the curious reader may ſee at large in Prideaux's Conn. ubi ſupra. Their houſes were mean; their cloaths made of wool, without any dye; they never changed their cloaths or ſhoes till they were quite worn out; their food was plain and coarſe, and their drink water; they neglected all bodily ornaments, and would by no means anoint themſelves with oil, according to the faſhion of thoſe times. They lived in ſodalities, and had all their goods in common; their morals were very exact and pure, and they kept the Sabbath more ſtrictly than any of the Jews. Before any of them were admitted to the common table, they bound themſelves by a ſolemn oath to obſerve the rules of the ſociety, which were very ſtrict and exemplary.

Some have ſaid that the Eſſenes, as well as the Pythagoreans, prohibited oaths; that they uſed only inanimate ſacrifices, and that they not only worſhipped towards the riſing ſun, but worſhipped the ſun itſelf. But it has been urged, that neither of theſe charges ſeem to be well founded; or at leaſt, that it is difficult to reconcile them with their known veneration for the writings of Moſes, and other inſtances of their conduct. Pliny, and others on his authority, have aſſerted, that they wholly declined marriage; and Pliny (lib. v. cap. 17.) with more wit than juſtice, ſays, that for ſeveral thouſand of years, this people is perpetually propagated without any being born among them, ſo fruitful and prolific unto them is the repentance of others. But Joſephus informs us (De Bell. Jud. lib. ii. cap. 1.) that there is one ſort of Eſſenes, who agreed with the others, except in the article of marriage. For they reckoned, that thoſe that do not marry cut off a great part from the number of the living, and that thus the whole race of mankind would ſoon be extinguiſhed. Accordingly they made choice of thoſe women, who, after three years trial, were found fit to bear children, and never cohabited with them after they were known to be with child; conſulting the propagation of their ſpecies, and not their own gratification in this buſineſs.

With reſpect to the religious opinions of the Eſſenes, they believed the exiſtence of angels, the immortality of the ſoul, and a future ſtate of rewards and puniſhments, but denied the reſurrection of the body. They maintained, that fate governs all things, and that nothing happens to man but by its appointment.

The Eſſeni ſeem to have been, among the Jews, what the moſt retired and auſtere monks are, or were, among the Chriſtians: which was what gave them their denomination of *Ιȣδαικοι ασκηται*, *Jewiſh aſcetics*.

Many Catholic writers have even deduced the origin of monks from them; building, principally, on what Philo relates of them, who divides them into two branches, or ſects; the one who married, and the other who lived in celibacy.

Joſephus ſeems likewiſe to have had an eye to theſe two ſorts of Eſſeni. Serrarius, who has wrote very amply on the ſubject, follows Philo in making two claſſes of Eſſeni. The firſt are thoſe whom he calls *Practici*, and who lived in community; the ſecond, thoſe called *Theoretici*, who lived in ſolitude, and led a life of pure contemplation. He adds, that Joſephus only makes mention of the firſt; omitting the contemplative kind, whom Philo calls *Therapeutæ*, and who were principally found in Egypt. See THERAPEUTÆ.

Euſebius holds, that the Eſſeni, called *Therapeutæ*, were real Chriſtians, or Jews converted by St. Mark, who had embraced this kind of life. Scaliger, on the contrary, maintains, that theſe Therapeutæ were no Chriſtians, but real Eſſeni, who made profeſſion of Judaiſm; however, he allows of the two kinds of Eſſeni above-mentioned. But Valeſius, in his notes on Euſebius, abſolutely rejects any ſuch diſtinction: he denies that the Therapeutæ were any real Eſſeni; and that chiefly on the authority of Philo himſelf, who never calls them Eſſeni, and who places the Eſſeni in Judæa and Paleſtine; whereas the Therapeutæ were ſpread throughout Greece, Egypt, and other countries.

Some traces of the Eſſenes are found under the emperor Trajan, and under Juſtinian; but they were much degenerated from their primitive purity both of doctrine and manners; and the ſect about that time became extinct. Though the Therapeutæ, as well as the Eſſenes, were ſtrictly Jews, and not Chriſtians, it is not impoſſible, that ſome of them, becoming Chriſtians, might ſtill affect their former recluſe way of living; and being imitated by others, laid the foundation of monkery among Chriſtians.

ESSENIAS, Andrew, in *Biography*, a learned Dutch divine, was born at Bommel in the year 1618. He was educated chiefly at Utrecht, was admitted to the exerciſe of the miniſtry in the year 1639, and in the following year took the degree of M. A. He obtained ſome preferment, and took his doctor's degree in the year 1645. Soon after this, he was choſen paſtor of the principal church at Utrecht, and in 1653 was appointed profeſſor of theology at that univerſity. He died in 1677, leaving behind him many works, that were very highly eſteemed by his contemporaries. He was what the world has uſually denominated an orthodox divine, and wrote againſt Crellius, and others among the Unitarians. One of his largeſt publications was "A Syſtem of Divinity," in 2 vols. His moſt popular piece was entitled "A ſhort View of Theological Controverſies, with an Index to Scripture Paſſages." This has gone through many editions. Moreri.

ESSENTIA Dulcis, in *Chemiſtry*, a name given by Kunkel, and ſome others of the German authors, to a menſtruum, of which they relate wonderful effects; but the preparation of which ſeems hitherto a ſecret. They ſay this menſtruum has nothing acid or corroſive in it, but that it approaches to the nature of ſpirit of wine, yet that it is capable of diſſolving the moſt denſe metals, and of converting any of them into a pure white ſalt, which has all their virtues, but nothing of that vitrolic acrimony, which they have when prepared in the common way. The ſalts of mercury and of gold thus prepared have great praiſes beſtowed on them, and are ſaid to cure epilepſies, the venereal diſeaſe, and many other diſtempers, without any violence or danger. Kunkel, De Salis Metal. See Metal.

ESSENTIAL, ſomething that is neceſſary to conſtitute a thing, or that has ſuch a connection with the nature and reaſon of a thing, that it is found, or ſuppoſed, wherever the thing itſelf is.

Thus, it is eſſential to God to be juſt. Mr. Locke has laboured to overturn that great principle of the Carteſians, that thinking is eſſential to the ſoul.

The heart, brain, and ſpinal marrow, are parts ordinarily ſuppoſed eſſential to life, or without which life cannot be; yet we have inſtances, in hiſtory, of children being found, and alive, without almoſt any of thoſe parts. See Brain, &c.

Essential *characters*, in *Natural Hiſtory*, or *Diagnoſtics*, are ſuch particulars as mark or diſtinguiſh a plant or animal from all others in the ſame genus or order. Mr. William Martin, in his "Outlines of the Knowledge of Extraneous Foſſils," p. 189, ſtates the principles under five heads, which ſhould direct the choice of parts of a foſſil animal or plant, to be conſidered as its diagnoſtic or eſſential characters. See Reliquia.

Essential *oils*. See Oils.

Essential *properties*, are ſuch as neceſſarily depend on and are connected with, the nature and eſſence of any thing, ſo as to be inſeparable from it; in diſtinction from *accidental*.

Essential *ſalts*, are thoſe prepared from decoctions, or thoſe which are found cryſtallized in the juices and infuſions of plants; in contradiſtinction to thoſe made by incineration. See Salt.

Essential *Fever*, *Form*, *Mode*, *Part*, *Perfection*. See the ſubſtantives.

ESSEQUEBO, or Esquivo, in *Geography*, one of the four provinces into which the Dutch poſſeſſions in Guiana are divided; the other three being Surinam, which is the chief ſettlement, Berbiſche or Berbiz, and Demerara. This ſettlement derives its name from that of the large river on which it is ſituated, and which at its diſcharge into the Atlantic is 3 leagues wide. The productions of this country are ſugar, coffee, and cotton. See Guiana, Surinam, Berbische, and Demerara.

ESSERA, a river of Spain, which runs into the Cinca, in Arragon.

ESSERA, Essere, or *Sere*, in *Medicine*, a generic denomination, uſed by the Arabian phyſicians, and compriſing ſeveral popular eruptions, and raſhes, which appear on the ſkin; eſpecially the eruption of the ſummer ſeaſon, in warm climates, which has been termed the Prickly-*heat*, the Nettle-*raſh*, the Prurigo of Dr. Willan's claſſification; &c. See theſe articles. See alſo Willan on Cutaneous Diſeaſes, genus Lichen.

ESSERUM, in *Geography*, a ſmall town of Denmark, in the iſland of Zealand, in the diſtrict of Cronburg, and the herred of Holboe. Before the Reformation it was remarkable for a rich monaſtery of Bernardines, founded in 1150, in an extremely pleaſant country, watered by lakes abounding in fiſh. But Eſſerum is now much more intereſting for a royal ſtud of horſes, and for having conſtantly flocks of the moſt renowned foreign ſheep, Spaniſh and others, which are diſtributed among the farmers to improve the Daniſh breed. In the beginning of the year 1800, there were at Eſſerum 652 choice ſheep, of which 223 ewes, and 33 rams, were Spaniſh of the beſt Merino breed. Catteau Tableau des Etats Danois, vol. ii. p. 147.

ESSES, in *Military Language*, are fixed to draught chains, made in the form of an S; one end of which is faſtened to the chain, and the other to hook to the horſe's harneſſes, or to a ſtaple; they ſerve likewiſe to lengthen and piece chains together.

ESSEX, in *Geography*, the name of one of the Engliſh counties, which has for its boundaries the German ocean and river Thames to the eaſt and ſouth; the counties of Suffolk and Cambridge to the north; and thoſe of Middleſex and Hertfordſhire on the weſt. The area of land thus encompaſſed meaſures about ſixty miles in length from eaſt to weſt, by fifty from north to ſouth: its circumference being about 225 miles. It is divided into 20 parts, of which fourteen are hundreds, five half hundreds, and one a royal liberty. Theſe are ſubdivided into about 400 pariſhes and townſhips, and twenty-five towns; containing, according to the late official report, 39,398 houſes, and 226,437 inhabitants. When the Romans invaded Britain, this diſtrict, with that now denominated Middleſex, were inhabited by a claſs or tribe of the Britons, called Trinobantes, or Trinovantes, who poſſeſſed, according to Cæſar, and ſome other ancient writers,

ters, two conſiderable cities or fortified towns; one, the ſite of modern London; and the other, that of Colcheſter in this county. This tribe was the firſt to ſubmit to and become vaſſals to the Romans, who, to keep them in ſubordination, eſtabliſhed five military ſtations within this diſtrict. Theſe were Durolitum, Cæſaromagus, Canonium, Camalodunum, and Ad Anſam. Theſe ſtations were all ſeated on the road which formed the fifth Iter from Londinium to Venta Icenorum, Caſtor in Norfolk. Camalodunum was unqueſtionably the principal ſtation in Eſſex, and though its ſite has been much conteſted by different writers, an attentive examination of the ſeveral places aſſigned, combined with a knowledge of the antiquities diſcovered in the vicinity of each, will admit little doubt of Colcheſter being the real ſituation. Eſſex formed a ſeparate and diſtinct kingdom during a certain period of the Saxon Heptarchy, and was called Eaſt-Seaxa; but the times of its eſtabliſhment and termination are not preciſely authenticated. Turner ſtates that this diſtrict, and Eaſt Anglia, were originally occupied by the Saxons at nearly the ſame period; and that Erkenwin was the firſt king of the former; commencing his reign in 527, and dying in 587.

By the Domeſday-book it appears, that ninety land-owners of this county were deprived of their lands by the Conqueror, during whoſe reign the whole civil and eccleſiaſtical eſtabliſhment of the kingdom, and of each county, underwent very conſiderable changes. Eſſex was now governed and tyrannized over by Norman barons, who conſtructed caſtles on their eſtates to ſecure themſelves, and to awe their dependant vaſſals. In the civil wars between the houſes of York and Lancaſter, and in thoſe of Charles's time, this county ſuffered greatly from the interference of the De Vere's in the former, and during the long ſiege of Colcheſter in the latter. Formerly there were twelve caſtles, or fortified buildings in this county; two of which, Landguard fort, and Tilbury fort, were denominated royal caſtles, as built for national ſecurity: the others were baronial reſidences, *viz.* Colcheſter, Hadleigh, Canfield, Hedingham, Clavering, Raleigh, Ongar, Pleſhy, Stanſtead-Montfichet, and Walden. Theſe formidable fortreſſes, though once the pride of the nobility, and the terror of the peaſantry, are moſtly raſed to the ground; the only parts remaining being their high keeps and wide foſſes. At Colcheſter, Hadleigh, Hedingham, and Walden, ſome parts of the walls ſtill remain. Eſſex compoſes part of that tract of country on the eaſtern ſide of England which forms the largeſt connected ſpace of level ground in the whole iſland; not one lofty eminence or rocky ridge being found in ſeveral contiguous counties. The ſurface of Eſſex is not, however, totally flat, having many gentle hills and dales; and towards the north-weſt, whence moſt of the rivers proceed, the country riſes, and preſents a continued inequality of ſurface. The moſt level tracts are thoſe of the ſouthern and eaſtern hundreds. The ſea-coaſt is broken into a ſeries of iſlets and peninſulas, deeply cut in by arms of the ſea, and exhibiting evident tokens of the force and effects of that reſtleſs element. Extenſive ſalt marſhes border moſt of the coaſt, the greater part of which is protected by embankments. The banks of the Thames, and the lower part near the ſea, are likewiſe low and marſhy. This county lies under a proverbial imputation of being particularly unhealthy; but this character can only apply to a ſmall part of it; as the middle and northern diſtricts are juſtly noted for a dry ſoil, and a wholeſome clear air. That part known by the name of the hundreds of Eſſex, bordering on the ſouth coaſt, from its low and marſhy ſituation, and expoſure to the eaſterly winds and ſea fogs, is certainly inimical to health, and many intermitting fevers proceed from theſe cauſes.

The principal productions of this county are wheat, barley, oats, beans, peas, turnips, tares, rape, muſtard, rye-graſs, and trefoil. Many diſtricts on the eaſt ſide are extremely productive: wheat is not unfrequently found to riſe to a load an acre; oats, (particularly the Poland,) to eleven or twelve quarters; beans and other corn in proportion. Among the more rare plants cultivated in Eſſex, are thoſe of coriander, teaſel, and carraway; many acres are alſo appropriated to the produce of hops, and various horticultural plants and roots. The latter are confined to the vicinity of large towns, and to the lands adjoining to the metropolis. Almoſt every ſpecies of ſoil is to be found within the limits of Eſſex, from the moſt ſtubborn to the mildeſt loam. The north-weſt ſide is characterized by a chalky ſubſtratum; but the eaſt and ſouth ſides abound with marſhy and boggy land, having abundance of gravel intermixed. Of waſte lands and foreſts, Meſſrs. Griggs (in their "General View of the Agriculture of Eſſex,") computed the county to contain fifteen thouſand acres; the greater part of which, they obſerve, is capable of producing corn. Since their report, however, many diſtricts have been incloſed and cultivated. Though Eſſex is not highly celebrated for its dairies, yet thoſe in the pariſh of Epping and its vicinity are famous for the richneſs of their cream and butter. The butter is moſtly ſent to London, where it bears a high character and price. Few counties have leſs minerals than Eſſex; which is alſo nearly exempt from quarries, or any maſs of rocks. In conſequence, the houſes are almoſt wholly built with brick; and many of them are ſingular and curious ſpecimens of brick-architecture. In conſtructing the caſtles, the monaſtic buildings, and many of the old manſion-houſes, the builders have endeavoured to render them not only durable monuments of their ſkill, but alſo examples of their taſte, diſplayed by a variety of ornaments in the cornices, doors, pilaſters, and particularly in the chimnies. Some mineral waters riſe in the county, but few have obtained much repute; that of Tilbury is occaſionally reſorted to, and found to be impregnated with ſome earthy and muriatic ſalts.

The principal rivers, properly belonging to this county, are the Colne, the Blackwater or Pant, the Chelmer, the Crouch, the Ingerbourn, the Roding, and the Cam. Beſides theſe, Eſſex partakes of other rivers, which ſerve as natural boundaries, and irrigate and fertilize its land: theſe are the Thames, the Lee, or Lea, the Stort, and the Stour.

In the early periods of our hiſtory, it is reaſonably preſumed, that the whole, or the greater part of Eſſex, was one extenſive foreſt. During the Britiſh and Roman governments, many parts muſt have been cleared for ſtations, roads, and cultivation: yet in the time of king Stephen it appears that the principal portion of the county was either foreſt, or ſubject to foreſt laws. In his reign, however, a large tract in the north-eaſt part of the county was diſafforeſted, and cultivated; and the remaining part, north of Stane-ſtreet, was diſafforeſted by king John. Henry the Third, in the twelfth year of his reign, directed perambulations to be taken of Waltham foreſt, in order to aſcertain its extent and value; and about the ſame time had large tracts cleared for the plough. This judicious plan was purſued by Edward the Firſt, in the twenty-ſixth and twenty-eighth years of his reign: yet much foreſt land ſtill remained; and Paul, viſcount Bayning, with many other gentlemen of the county, purchaſed of the crown, and diſafforeſted ſeveral parts of it. Theſe proceedings, combined with the more equitable deciſions of ſubſequent monarchs, occaſioned the foreſts to contract their boundaries, and be leſs injurious to the public. While the foreſts continued in the crown, and were under the local government of arbitrary foreſters and ſtewards, the ſubject, whoſe eſtate was contiguous, ſuffered repeated oppreſſions. The grievance was partly redreſſed in the perilous reign of king John, when the barons compulſively procured from that monarch the "Charter of Foreſts," by which many of theſe royal diſtricts were diſafforeſted, and ſtripped of their oppreſſive privileges; while more lenient regulations were adopted in the government of thoſe that remained. The foreſts of Epping and Hainault ſtill retain the name, and ſupport a few deer, &c. The office of chief foreſter for Eſſex was deemed highly honorary, and was generally beſtowed on ſome illuſtrious perſon. The ſtewardſhip was alſo an office of great conſequence, and was uſually enjoyed by ſome of the nobility. It continued in the De Veres, earls of Oxford, for many generations, but was taken from them by Edward the Fourth, on account of their adherence to the Lancaſtrian party. On the acceſſion of Henry the Seventh, it was reſtored by grant to John, earl of Oxford. The ſteward had power to ſubſtitute a lieutenant, one riding foreſter, and three yeomen-foreſters, in the three bailiwicks of the foreſt. He alſo had many lucrative privileges, and was keeper of Havering at Bower, and of the houſe and park there.

Previous to the diſſolution, Eſſex contained forty-ſeven religious houſes: of theſe, two were mitred abbies; ſix common abbies; twenty-two priories; three nunneries; three colleges; two præceptories of templars; and nine hoſpitals.

Eſſex is included in the dioceſe of London, and contains three archdeaconries and fifteen deaneries; it returns eight members to parliament, *viz.* two for the county, two for Malden, two for Harwich, and two for Colcheſter: it is in the home circuit; pays twenty-four parts of the land-tax, and ſupplies 960 men for the militia.

Essex, one of the moſt populous and beſt cultivated counties in Maſſachuſetts, in the United States of America; bounded N. by North Hampſhire, E. and S. by the ocean, and the town of Chelſea in the county of Suffolk, and W. by Middleſex county; 38 miles long and 25 broad; of a triangular ſhape, Chelſea being the acute point. It is ſubdivided into 22 townſhips, containing 7644 houſes, and 61,196 inhabitants, about 135 to each ſquare mile. The firſt ſettlement in Maſſachuſetts proper was made in Salem, the capital of this county, in 1628, and it was made a ſhire in 1643, being one of the three into which the colony was divided. Eſſex county pays about $\frac{1}{7}$th part of the ſtate-tax, elects ſix ſenators for the government of the commonwealth, and two repreſentatives in the legiſlature of the United States. The principal towns are Salem, Newbury-port, Glouceſter, Marblehead, Beverly, Newbury, and Ipſwich; and in it are two academies, one at Byefield, and another at Andover. The face of the county is agreeably variegated with hills, vales, plains, and woods; the land is generally fruitful, but more ſuited to the culture of barley than moſt other parts of the ſtate; it has quarries of marble and limeſtone, and the coaſt is indented with a number of good harbours. The north part of Eſſex county is interſected by Merrimack river; and between it and the North Hampſhire line is a ſtrip of land three miles wide, divided into the towns of Methuen, Haverhill, Almſbury, and Saliſbury, containing 1429 inhabitants. The chief iſland on the coaſt of this county is Plum iſland.

Essex, a county in Upper Canada, bounded on the E. by the county of Suffolk, on the S. by lake Erie, on the W. by the river D'Etroit to Maiſonville's mill, thence by a line running parallel to the river D'Etroit and lake St. Clair, at the diſtance of four miles, till it meets the river Thames, and thence up the ſaid river, to the N.W. boundary of the county of Suffolk. This county ſends one repreſentative to the provincial parliament.

Essex, a county in Virginia, bounded E. and N.E. by Rappahannock river, which divides it from Richmond county; about 55 miles in length and 12 in breadth, and containing 3741 free inhabitants, and 5767 ſlaves.

Essex, a county in New Jerſey, ſituated in the eaſtern part of the ſtate, and ſeparated from Staten iſland by Newark bay. It is about 25 miles in length and 16 in breadth, and has three townſhips, *viz.* Newark, Elizabeth-town, and Acquackanack, containing 22,269 inhabitants, of whom 1521 are ſlaves. The ſoil is fertile, and its productions find a ready ſale in the city of New-York. This county comprehends ſeven Preſbyterian churches, three for Epiſcopalians, one for Anabaptiſts, and two for Dutch Calviniſts.

Essex, a county of New-York, having on the north Clinton county, on the ſouth Waſhington county, and on the eaſt lake Champlain, which ſeparates it from Vermont.

Essex, a county in Vermont, bounded N. by Canada, and E. by Connecticut river, containing 1429 inhabitants.

Essex, a townſhip in Chittenden county, in Vermont, containing 729 inhabitants, and lying between Jericho on the S.E. and Colcheſter on the N.W.

Essex *Valley Mountains*, mountains of the iſland of Jamaica; 10 miles S.S.E. of Lacovia.

ESSEY, a town of France, in the department of Orne, and diſtrict of Alençon; 3 leagues N.E. of Alençon.

ESSLISORS. See Elisors.

ESSOIGN, or Essoin, in *Law*, an excuſe for him who, being ſummoned to appear and anſwer to an action real, or to perform ſuit to a court baron, &c. cannot attend, becauſe of ſome legitimate hindrance.

The word is formed of the French *eſſoine*, or *exoine*; and that from the barbarous Latin *eſſonia*, or *exonia*, which ſignifies the ſame.

The cauſes that ſerve to eſſoin, are various; yet they may be reduced to five heads. The firſt is, *eſſoin de ultra mare*, when the party is beyond ſea; by which the defendant ſhall have 40 days: the ſecond, *de Terra Sancta*, when on an expedition in the Holy Land, and the defendant ſhall have a year and a day; the third, *de malo veniendi*, when he is infirm of body, and cannot come; which is alſo called the common eſſoin; the fourth, *eſſoin de malo lecti*, when the defendant is ſick a-bed, and may by writ be viewed by four knights; the fifth, *de ſervitio regis*, when he is in the king's ſervice. Beſides theſe, there are ſeveral other excuſes to ſave a default in real actions, as conſtraint of enemies, floods of water, &c. 2 Co. Inſt. 125.

Essoign *day of term*, is the firſt day of that term when the court ſits to take eſſoigns, or excuſes, for ſuch as do not appear according to the ſummons of the writ; *e. g.* the octave of St. Hilary, or the eighth day incluſive after the feaſt of that ſaint; which falling on the 13th of January, the octave, therefore, or firſt day of Hilary term, is the 20th of January. But the perſon ſummoned hath three days grace beyond the return of the writ, in which to make his appearance; and if he appear on the fourth day incluſive, the *quarto die poſt*, it is ſufficient.

Essoign *de malo villæ*, is when the defendant is in court the firſt day, but gone without pleading; and being afterwards ſurpriſed with ſickneſs, &c. cannot attend, but ſends two eſſoigners, who openly proteſt in court that he is detained by ſickneſs in ſuch a village, that he cannot come *pro lucrari et pro perdere;* and this will be admitted: for it lieth on the plaintiff to prove, whether the eſſoign is true or not.

Essoigns, *Clerk of the.* See Clerk.

ESSOMMES, in *Geography*, a ſmall town of France, in the department of the Aiſne, on the river Marne; 3 miles S.W of Château Thierry.

ESSONE, a river of France, in the department of Seine and Oiſe, which has its ſource near Pithiviers in the foreſt of Orleans, flows by Ferté Alais, receives the Juine near Saint Vrain, 3 miles above Villeroi, and falls into the Seine near Corbeil. It has lately been rendered navigable.

ESSONNE, a ſmall town of France, in the department of Seine and Oiſe, near the river Eſſone, 24 miles S. of Paris, and 24 miles N. of Fontainbleau, remarkable for its manufactures of gunpowder and of writing paper.

ESSORANT, from the French *eſſorer*, to air, in order to dry, in *Heraldry*, a term uſed to expreſs a bird ſtanding on the ground with the wings expanded, as if it had been wet, and were drying itſelf.

ESSOYES, in *Geography*, a ſmall town of France, in the department of the Aube, chief place of a canton in the diſtrict of Bar-ſur-Seine, with a population of 1585 individuals, 15 miles S.W of Bar-ſur-Aube. Its canton contains 21 communes, and 11,655 inhabitants, on a territorial extent of 375 kiliometres.

ESTABLISHMENT *of Dower*, in *Law*, is the aſſurance or ſettlement of dower made to the wife by the huſband on marriage; and *aſſignment of dower* ſignifies the ſetting it out by the heir afterwards, according to the eſtabliſhment. See Dower.

Establishment *of Religion*. See Religion.

ESTACHE, is uſed in our *Old Writers*, for a bridge or ſtank of ſtone and timber.

ESTAFFLISCHEN, in *Geography*, a town of Poland, in the palatinate of Kaliſh; 14 miles N.E. of Kaliſh.

ESTAFORT, a town of France, in the department of the Lot and Garonne, and diſtrict of Agen; 3 leagues S. of Agen.

ESTAGEL, a town of France, in the department of the Eaſtern Pyrenées; 3½ leagues N.W. of Perpignan.

ESTAGNAC, a ſmall town of France, in the department of the Charente; 33 miles E. of Angoulême.

ESTAIN. See Etain.

ESTAING, a ſmall town of France, in the department of the Aveyron, chief place of a canton in the diſtrict of Eſpalion, with a population of 1075 individuals. It is ſituated 18 miles N. of Rhodéz. Its canton contains 12 communes and 6700 inhabitants on a territorial extent of 195 kiliometres.

ESTAIRE, a ſmall town of France, in the department of the North, on the river Lys, between Merville and Armentieres; 15 miles W. of Lille.

ESTAMBOLIC, or Istambol-Antir, a town of Arabia, in the ſheriffal of Mecca, near the coaſt of the Red ſea; 180 miles N.N.W. of Medina.

ESTAMPES. See Etampes.

ESTANDARD. See Standard.

ESTANFORDE, in *Geography*, a town of Flanders; 12 miles S.W. of Ypres.

ESTAPA, or Istapo, a town of North America, in Mexico, and province of Tabaſco, ſituated on a river of the ſame name; 10 miles S.W. of Villa Hermoſa.

ESTAPLES. See Etaples.

ESTAPO, a ſtrong town of America, in New Spain, inhabited by Spaniards and native Americans, ſituated at the mouth of the river Tlaluc. N. lat. 17° 30′. W. long. 103° 5′.

ESTARREJA, a town of Portugal, in the province of Beira; 18 miles S. of Oporto.

ESTATE, in *Law*, the title or intereſt which a man hath in lands or tenements, &c. An eſtate in lands, tenements, and hereditaments, ſignifies (ſays judge Blackſtone) ſuch intereſt as the tenant hath therein; ſo that if a man grants all *his eſtate* in Dale to A. and his heirs, every thing that he can poſſibly grant ſhall paſs thereby. (Co. Litt. 345.) It is called in Latin *ſtatus*, ſignifying the condition or circumſtance in which the owner ſtands with regard to his property. For aſcertaining this with accuracy, eſtates may be conſidered in a three-fold view: firſt, with regard to the *quantity of intereſt* which the tenant has in the tenement; ſecondly, with regard to the *time* at which that quantity of intereſt is to be enjoyed; and, thirdly, with regard to the *number* and *connexions* of the tenants.

I. The *quantity of intereſt* which the tenant has in the tenement is meaſured by its duration and extent. Thus, either his right of poſſeſſion is to ſubſiſt for an uncertain period, during his own life, or the life of another man; to determine at his own deceaſe, or to remain to his deſcendants after him; or, it is circumſcribed within a certain number of years, months, or days; or, laſtly, it is infinite and unlimited, being veſted in him and his repreſentatives for ever. This occaſions the primary diviſion of eſtates, into ſuch as are *freehold*, and ſuch as are *leſs than freehold*. See Freehold.

Eſtates of freehold, underſtood as they are defined under that article, are either eſtates *of inheritance*, or eſtates *not of inheritance*. The former are again divided into inheritances *abſolute* or fee-ſimple, and inheritances *limited*, one ſpecies of which is uſually denominated fee-tail. See Fee, Fee-simple, and Fee-tail.

Of eſtates of freehold, not of inheritance, but *for life* only, ſome are *conventional*, or expreſsly created by the acts of the parties; others are merely *legal*, or created by conſtruction and operation of law. As to eſtates for life, expreſsly created by deed or grant; ſee Life-estate. As to the eſtate of tenant in tail after poſſibility of iſſue extinct; ſee Tail and Fee-tail. As to tenant by courteſy, and tenant in dower; ſee Tenant and Dower.

Of eſtates that are leſs than freehold, there are three ſorts; *viz.* 1. Eſtates for years; 2. Eſtates at will; 3. Eſtates by ſufferance. For the two former, ſee Lease; and for the latter, ſee Sufferance.

Beſides the ſeveral diviſions of eſtates above enumerated, in point of intereſt, there is another ſpecies which is called an eſtate *upon condition*; being ſuch whoſe exiſtence depends upon the happening or not happening of ſome uncertain event, whereby the eſtate may be either originally created, or enlarged, or finally defeated. (Co. Litt. 201.) Eſtates upon condition are of two ſorts: 1. Eſtates upon condition *implied*; 2. Eſtates upon condition *expreſſed*: under which laſt may be included, 3. Eſtates held in *vadio*, *gage*, or *pledge*; 4. Eſtates by *ſtatute-merchant* or *ſtatute-ſtaple*; 5. Eſtates held by *elegit*. See theſe ſeveral articles.

II. Eſtates, with regard to the *time of their enjoyment*, when the actual receipt of the rents and profits commences, may be conſidered either in *poſſeſſion* or in *expectancy*; as to eſtates in poſſeſſion, ſometimes called eſtates *executed*, whereby a preſent intereſt paſſes to and reſides in the tenant, not depending on any ſubſequent circumſtance or contingency, as in the caſe of eſtates *executory*; all thoſe above-mentioned are of this kind; but the doctrine of eſtates in expectancy contains, ſays Blackſtone, ſome of the niceſt and moſt abſtruſe learning in the Engliſh law. Of expectancies there are two ſorts; one created by the act of the parties, called a *remainder*; the other by act of law, and called a *reverſion*. See REMAINDER and REVERSION. See alſo EXECUTORY *Deviſe* and LIMITATION.

III. Eſtates conſidered with reſpect to the *number and connexions* of their owners, or the tenants who occupy them, whatever be their quantity or length of duration, and whether they be in actual poſſeſſion or expectancy, may be held in four different ways: *viz.* in *ſeveralty*, in *joint-tenancy*, in *coparcenary*, and in *common*. See SEVERALTY, JOINT-TENANCY, COPARCENARY and PARCENERS, and TENANTS *in common*.

With regard to the title to eſtates and the different modes of tenure; ſee TITLE and TENURE.

Eſtates are acquired divers ways, *viz.* by deſcent from a father to the ſon, &c. conveyance or grant from one man to another; by gift or purchaſe, deed, or will; and a fee-ſimple is the largeſt eſtate that can be in law. 1 Litt. 541.

Eſtates are real, of lands, &c. or perſonal, of goods and chattels; otherwiſe diſtinguiſhed into freeholds that deſcend to the heir, and chattels, which go to the executors. The word eſtate, generally, in deeds, grants, and conveyances, comprehends the whole, in which the party hath an intereſt or property; and will paſs the ſame. 3 Mod. 46.

ESTATE, *additions of*. See ADDITION.

ESTATE, *baſe*. See BASE.

ESTATE, *que*. See QUE *eſtate*.

ESTATE, or ſimple *State*, denotes alſo the empire, kingdom, provinces, or extent of lands under the government of any ſovereign.

The eſtates of the grand ſeignor, of the king of Spain, &c. are very extenſive; thoſe of the king of France were before the revolution compact, and well peopled. Italy was formerly cantoned out into a great number of petty ſtates. We ſay, miniſters of eſtate, ſecretaries of ſtate, &c.

ESTATE, or *State*, is alſo generally applied in the ſame ſenſe with claſs or order; thus, the lay part of his majeſty's ſubjects, or ſuch of the people as are not comprehended under the denomination of clergy, may be divided into three diſtinct eſtates or ſtates, the civil, the maritime, and the military. See each term.

ESTATE is more particularly applied to the ſeveral ranks or claſſes of a people aſſembled together, for concerting meaſures, reforming public abuſes, or compoſing the diſturbances of a ſtate. In England, the three eſtates, *viz.* king, lords, and commons, meet ordinarily in parliament. See PARLIAMENT.

ESTATES *General*.
ESTATES *of Holland*. } See STATES *General*, &c.

ESTAVAYER, in *Geography*, a ſmall town of Switzerland, in the canton of Fribourg, pleaſantly ſituated on the eaſtern ſhore of the lake of Neufchatel. N. lat. 46° 46′.

ESTE, a town of Italy, in the Paduan; 11 miles S.S.W. of Padua.

ESTELLA, a handſome manufacturing town of Spain, in Navarre, with an univerſity in its neighbourhood, founded A.D. 1565. It contains ſeveral churches and convents, and 4500 inhabitants, defended by a caſtle, ſituated in a plain, watered by the rivers Ega and Ureder; 6 leagues S.W. of Pampeluna. The environs of this place are agreeable and fertile.

ESTELMUR, a town of Aſiatic Turkey, in the province of Caramania; 120 miles S. of Cogni.

ESTENIDE. See EKSENIDE.

ESTEPA, a town of Spain, in the province of Seville, or, according to ſome geographers, in that of Granada; celebrated for its olives and oil; 15 miles S. of Ecija.

ESTEPONA, a ſmall fiſhing town of Spain, ſituated near the coaſt in the province of Granada, between Gibraltar and Marbella. Its territory furniſhes abundance of wine.

ESTERLING, or EASTERLING. See STERLING.

ESTERNAY, in *Geography*, a ſmall town of France, in the department of the Marne, chief place of a canton in the diſtrict of Epernay, with a population of 835 individuals. Its canton has 23 communes and 6498 inhabitants, upon a territorial extent of 325 kiliometres.

ESTETÉ, in *Heraldry*, is uſed by the French to ſignify a beaſt whoſe head has been, as it were, torn off by force, and, conſequently, the neck left rough and ragged; in contradiſtinction to deffait, or decapité, where the neck is left ſmooth, as if the head had been cut off.

ESTEVE, M. in *Biography*, a writer on the theory of muſic, or rather of ſound or harmonics. He has attacked the demonſtration of the principles of harmony by Rameau, in which M. Laborde allows him to have reaſon on his ſide: however, as he does not build his ſcale by the triple progreſſion of Pythagoras, in the way which the abbé Rouſſier preſcribes, and without which ſeries of perfect fifth he thinks there never was nor ever can be any muſic fit to be heard, M. Eſteve has not been honoured with the ſeal of Meſſrs. Laborde and Rouſſier's approbation. He has, however, explained the cauſe of more and leſs perfection in concords, from the coincidences of vibration, which has been known ever ſince the time of Galileo, (ſee BASSE *fondamentale*), but never ſo clearly explained in France.

ESTHER, a canonical book of the Old Teſtament: denominated from a celebrated Jewiſh captive of that name, in Perſia, whoſe beauty preferred her to the bed of Ahaſuerus (ſuppoſed by ſome to have been Darius Hyſtaſpis, by others Xerxes, but probably Artaxerxes Longimanus, though Jacob. Capellus makes him to be Ochus, called in Perſia Achaſch-Veroſh), and the throne of Perſia; and who, in that quality, ſaved her countrymen, the Jews, from the death to which Ahaſuerus had doomed them, by the counſels of his favourite Haman; who wiſhed thus to be revenged on Mordecai for withholding from him that reſpect to which he conceived himſelf entitled. Mordecai informed the queen of the danger to which her nation was expoſed; and induced her to wait upon the king, and invite him and Haman to a ſumptuous banquet which ſhe had prepared. Haman was puffed up with this high honour, and thought himſelf ſure of accompliſhing his ample ſcheme of vengeance. During the interval, the king chanced to read the public records, which reminded him of Mordecai's having diſcovered a conſpiracy that had been formed againſt him. Determined to diſtinguiſh him by ſome ſignal token of favour, he ordered Haman to conduct Mordecai in triumph through the city. The queen having diſcovered to Ahaſuerus, that ſhe belonged to the Jewiſh nation, intreated juſtice againſt Haman on behalf of her people, for the deſtruction of whom he had obtained the king's decree. Ahaſuerus ordered Haman to be hanged on the gallows which he had erected for the execution of Mordecai; revoked the decree iſſued forth againſt the Jews, and granted another, by which he permitted them to avenge themſelves on their enemies on the day appointed. After the death of Haman, the king beſtowed his eſtates upon Mordecai, and admitting him into his confidence, as the acknowledged uncle of the queen, advanced him to a ſtation of high office and truſt in his court. The hiſtory of this tranſaction makes the ſubject of the book of Eſther. Eſther was of the tribe of Benjamin, and a deſcendant from one of thoſe families, which had been carried into captivity by Nebuchadnezzar, king of Babylon, and afterwards ſettled in the city of Shuſhan. She was the niece of Mordecai, and her Jewiſh name was "Hadaſſeh."

The critics are divided about the author of this book: St. Epiphanius, St. Auguſtine, and Iſidore, attribute it to Ezra; but Euſebius will have it to be of a later date. Some aſcribe it to Joachim, high prieſt of the Jews, and grandſon of Joſedek; others will have it compoſed by an aſſembly, or ſynagogue, of the Jews, to whom Mordecai wrote letters, informing them of what happened. Eſth. ix. 29.

But the generality of interpreters, Hebrew, Greek, Latin, &c. aſcribe the book to Mordecai himſelf; Elias Levita, in his Maſſ. Hamum. pref. 3. mentions this opinion as unqueſtionable.

It is chiefly founded on that paſſage, chap. ix. ver. 20. where it is ſaid, that "Mordecai wrote theſe things, and ſent letters unto all the Jews, that were in all the provinces, &c." It is alſo ſuppoſed that queen Eſther herſelf might have ſome ſhare therein: it being expreſſed in the ſame chapter, ver. 29. that Eſther and Mordecai wrote a ſecond letter, by the king's authority, to ordain the ſolemnizing a yearly feaſt, called *purim*, that is, *day of lots*, in commemoration of the Jews being delivered from the lots, or ſortes, whereby they had been condemned.

Some will have this book to be deuterocanonical, or apocryphal; others contend for its being canonical, as far as chap. x. ver. 3. incluſive; and all the reſt deuterocanonical. Of this ſentiment are, St. Jerome, De Lyra, Dionyſius the Carthuſian, Cajetan, and others. The council of Trent turned the ſcale for its being canonical throughout; ſo that the matter is determined for the Catholic countries.

But the Proteſtants retain the old opinion, and only admit it as far as the third verſe of the tenth chapter; the reſt, to the end of the ſixteenth chapter, is thrown among the apocryphal books. See Canon and Apocrypha.

Esther *Town*, in *Geography*, a town of America, in the county of Lancaſter, and ſtate of Pennſylvania, ſituated on the eaſt bank of the Suſquehannah river, a little N. of Harriſburg.

ESTHIO'MENOS, (from ἐσθίω, *to eat*,) in *Surgery*, the diſeaſe called herpes exedens. Alſo any obſtinate ulcer, which continues to eat away the parts.

ESTHONIA, in *Geography*, is the ancient name of the Ruſſian government of Reval, on the ſouthern coaſt of the gulf of Finland, over-againſt Finland Proper. In the year 1386 Eſthonia was ſold to the Teutonic order, and formed a part of Livonia; with which, after a ſeparation of a hundred years, when it was under the dominion of Sweden, it was united to the Ruſſian territory.

Not only the government of Reval, but alſo the greater part of Livonia, or five circles of the government of Riga, are inhabited by Eſthonians. In the former they probably amount to 180,000, in the latter to 257,000 individuals. The language, manners, complexion, dwellings, and huſbandry of the Eſthonians prove their relationſhip to the Finns, who are one of the moſt far ſpread nations of the globe, extending from the ſhores of the Baltic to the remoteſt confines of Aſia. In the Ruſſian annals, where they act a conſiderable part, as they, in common with the Novgorodian Slavi, founded the Ruſſian ſtate, the Eſthonians are called *Tſchudes*. Tooke's View of the Ruſſian Empire, vol. i.

ESTIÆA, Εςιαια, in *Antiquity*, ſolemn ſacrifices to Veſta, called in Greek εςια, of which it was unlawful to carry any away, or communicate any part to any beſide the worſhippers. Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 396.

ESTIATORES, Εςιατορες, among the Athenians, perſons appointed by lot to provide an entertainment for the whole tribe. Beſides thoſe appointed by lot to this office, others voluntarily undertook it to ingratiate themſelves. Potter, Archæol. Græc. lib. i. cap. 15. tom. i. p. 86.

ESTIMIONE, in *Natural Hiſtory*, a name by which ſome call the *barmeſion*.

ESTISSAC, in *Geography*, a ſmall town of France, in the department of the Aube, chief place of a canton in the diſtrict of Troyes, with a population of 1255 individuals. Its canton has 6089 inhabitants, diſperſed in 10 communes, on a territorial extent of 200 kiliometres.—Alſo, a ſmall town of France, in the department of the Dordogne, 18 miles N. E. of Bourdeaux.

ESTIVAL, a town of France, in the department of the Voſges, and diſtrict of St. Diey; 2 leagues N. of St. Diey.

Estival *occident*. See Occident.

Estival *orient*. See Orient.

Estival *ſolſtice*. See Æstival, and Solstice.

ESTIVAREILLES, in *Geography*, a town of France, in the department of the Allier, and diſtrict of Montluçon; 5 miles N. of Montluçon.

ESTIUS, William, in *Biography*, a learned Dutch divine, was born at Gorcum in Holland in the year 1542. He received the early part of his education at Utrecht, and finiſhed his ſtudies in philoſophy and theology at Louvain, where he afterwards became an inſtructor. In 1580 he was admitted to the degree of doctor in divinity, and was ſucceſſively choſen profeſſor of theology, in the univerſity of Douay; ſuperior of that ſeminary, and afterwards its chancellor. He died in 1613 at the age of 71, while he was in the diſcharge of the various duties of his laborious office at Douay, highly eſteemed on account of his modeſty, piety, and active virtues. He had ever been indefatigable in his ſtudies, and zealous in promoting the intereſts of thoſe committed to his care. As an author his principal works are, "Commentarii in omnes S. Pauli et VII. Catholicas Apoſtolorum Epiſtolas," in two volumes folio. "Annotationes in præcipua ac difficiliora S. Scripturæ Loca." Another work is mentioned with much applauſe, it is a diſcourſe "Contra Avaritiæ Scientiæ," intended to expoſe thoſe who lock up their learning in their cloſets, and refuſe to communicate it to the public by uſeful writings, or to individuals by well-timed and ſeaſonable advice. The writings of Eſtius are recommended by Du Pin as exceedingly uſeful to young theologians in their enquiries after truth. Moreri.

ESTOILE'. A croſs eſtoilé is a ſtar with only four long rays, in manner of a croſs; and accordingly broad in the centre, and terminating in ſharp points.

ESTOILLE, Peter de l', in *Biography*, who flouriſhed towards the cloſe of the ſixteenth century, was educated to the profeſſion of the law, and became grand audiencer of the chancellery of Paris. He died in 1611, and after his death was publiſhed from his manuſcripts "A Journal of the reign of Henry III." which has paſſed through many editions; of theſe the laſt was edited by the Abbè Lenglet du Freſnoi in 5 vols. 8vo. The ſame learned editor gave to the public "L'Eſtoille's Journal of the reign of Henry IV." in four volumes, 8vo. This, as well as the other work, is enriched by ſome curious pieces not to be found in the preceding editions. The ſtyle and manner of theſe journals poſſeſs much ſimplicity, exhibiting the air of truth, and affording a lively and accurate picture of the times. Moreri.

Estoille, Claude de l', ſon of the preceding, was a poet, and admitted a member of the French academy in the year 1632. He was patronized as a dramatic writer by Richlieu, but his pieces were not well received by the public, though he is allowed to have had a talent at verſification, and a thorough knowledge of the rules of the ſtage. He was a rigid cenſor of his own performances, and of thoſe of others, and is ſaid to have occaſioned the death of a young author by the ſeverity of his criticiſm on a comedy put into his hands. He died in 1652 about 50 years of age. He had obtained, and richly deſerved, the character of an honourable and truly independent man. In the earlier part of life, though ill provided for with reſpect to fortune, he choſe to quit the capital with a wife whom he loved, rather than ſubmit to the meanneſſes which men of letters are too much inclined to practiſe in courting the opulent. Moreri.

ESTOPPEL, formed of the French *eſtouper*, *oppilare*, *obſtipare*, to ſtop, or block up, in *Law*, an impediment, or bar of action, ariſing from a man's own act, or deed; againſt which a man is forbidden, by law, to ſpeak, though it be to ſay the truth. See Bar.

Goddard defines an eſtoppel to be any bar, or hindrance, to one to plead the truth; and extends it not only to the impediment given by his own act, but by another's alſo. There are three kinds of eſtoppel; *viz.* by matter of record, by matter in writing, and by matter in pais.

ESTOVERS, is uſed by Bracton, (l. iii. tr. 2. c. 18.) for that ſuſtenance which a man, committed for felony, is to have out of his lands, or goods, for himſelf and his family, during impriſonment.

In ſtat. 6 Edw. 1. it is uſed for an allowance in meat, or cloaths. In ſome manors the tenants have common of eſtovers; that is, neceſſary botes, or allowances, out of the lord's wood; in which laſt ſenſe, eſtovers comprehends houſe-bote, hay-bote, and plow-bote; ſo that if a man have in his grants theſe general words, "de rationabili eſtoverio in boſcis, &c." he may thereby claim all three.

Eſtovers is alſo uſed for alimony, which if the huſband refuſes to pay, there is, beſides the ordinary proceſs of excommunication, a writ at common law, "de eſtoveriis habendis," in order to recover it.

ESTOURMELLES, in *Geography*, a town of France, in the department of the North, and diſtrict of Cambray; 1½ league E. of Cambray.

ESTOUTEVILLE, a ſmall town of France, in the department of the Lower Seine, 12 miles N. of Caudebec.—Alſo, a ſmall town of France, in the ſame department, 15 miles N. of Rouen.

ESTRAC, in the *Manege*, ſignifies a horſe that is light bodied, lank-bellied, thin flanked, and narrow-cheſted. See Belly.

ESTRADE, a French term, literally ſignifying a public road, or highway. Hence the military phraſe, *battre l'eſtrade*, to beat the eſtrade, that is, to ſend ſcouts, or horſemen to get intelligence, to learn the diſpoſitions of the enemy, and inform the general of every thing likely to fall in the way. An army never marches without ſending batteurs d'eſtrade on every ſide.

The word is formed of the Italian *ſtrada*, ſtreet, or road; which is derived from the Latin *ſtrata*, a paved ſtreet. Some derive it from *eſtradiots*, who were cavaliers anciently employed in beating the eſtrade.

Estrade is alſo uſed for a little elevation of the floor of a room, frequently encompaſſed with an alcove, or rail, for placing a bed in; and ſometimes, as in Turkey, only covered with fine carpets, for receiving viſitors of diſtinction.

ESTRADES, Godfrey *Count of*, in *Biography*, was at an early age deſigned for the profeſſion of arms, and ſerved under prince Maurice in Holland, with whom he acted as agent of the French court, and afterwards attained the high honour of marſhal of France. He was highly eſteemed as a diplomatic character, and in the year 1661 went to England as embaſſador extraordinary, where he maintained with ſpirit the precedence of the crown of France to that of Spain. In the following year he went to Holland in the ſame character, and concluded the peace of Breda. He was intruſted with the important negociation for a general peace at Nimeguen, and acquitted himſelf to the ſatisfaction of all concerned. He ſuſtained with high reputation various other diplomatic characters, and in 1685 was nominated governor to the duke de Chartres, but died within a few months, at the age of ſeventy-nine. The count left behind him an abundance of MSS. concerning the different negociations in which he had been engaged: from theſe, which conſiſted of twenty-two volumes folio, a collection was publiſhed in 1709, entitled "Letters, Memoirs, and Negociations of the Count d' Eſtrades." An improved edition was publiſhed in 1743 at the Hague, in 9 vols. 12mo.

ESTRANGEL, Estrangelus, in the Syriac *Grammar*. Eſtrangel character, is a particular ſpecies, or form, of Syriac letter; ſerving as the majuſcule letters in that language.

Abraham Ecchellenſis takes the eſtrangel character for the true ancient Chaldee characters; and it is certain the Abyſſinians, who call themſelves Chaldeans, ſtill occaſionally uſe the eſtrangel character, if we may credit Hottinger, in his Theſaur. Philol. p. 286. Biſhop Walton, in his Prolegomena, gives us an eſtrangel alphabet.

ESTRAPADE, in the *Manege*, is the defence of a horſe that will not obey, but to get rid of his rider, riſes much before, and while his forehand is yet in the air, yerks furiouſly with his hind legs, ſtriking higher than his head was before; and during his countertime goes back rather than advances.

ESTRAY, or Stray, ſignifies any tame beaſt, or ſheep, oxen, ſwine, and horſes, or ſwans, found within a lordſhip, and not owned by any man; in which caſe being cried, according to law, in the church, and two market-towns adjoining, if it be not claimed by the owner, within a year and a day, it becomes the lord's of the ſoil where found. If the owner claims it within the year and day, he muſt pay the charges of finding, keeping, and proclaiming; and he may ſeize it, without telling the marks, or proving his property, which may be done at the trial if conteſted. If the beaſt ſtray within the year to another lordſhip, the firſt lord cannot retake it. An eſtray muſt be fed and kept, uninjured, and without labour, till it is reclaimed, or the limited time expires.

ESTREAT, Extractum, in *Law*, is uſed for the true copy, or duplicate, of ſome original writing, eſpecially of amercements, or penalties, ſet down in the rolls of a court, to be levied by the bailiff, or other officer, on every offender. Juſtices, commiſſioners, &c. are to deliver their eſtreats into the exchequer yearly, after Michaelmas; and fines to have writs, which ſhall be entered in the eſtreat, in order as they are entered in the chancery rolls, &c. ſtats. 51 Hen. III. ſtat. 5. 16 Edw. II. All forfeited recognizances are to be firſt eſtreated in the exchequer by ſheriffs of counties; on which proceſs iſſues to levy the ſame to the uſe of the king. Stat. 22 and 33 Car. II. cap. 22.

Sheriffs' eſtreats muſt be in two parts, indented and ſealed by the ſheriff, and two juſtices of peace; who are to view them, and one of them is to remain with the ſheriff, and the other with the juſtices. Stat. 11 Hen. VII. c. 15. The eſtreats of fines, at the quarter-ſeſſions, are to be made by the juſtices; and to be double, one of which is to be delivered to the ſheriff by indenture. Stat. 14 R. II. c. 2. Fines, poſt-fines, forfeitures, &c. muſt be eſtreated into the exchequer twice a year, on pain of 50*l.* And officers are to deliver in their returns of eſtreats upon oath. Stat. 22 & 23 Car. II. c. 22. 4 and 5 W. & M. c. 24. It is the courſe of the court of B. R. to ſend the eſtreats into the exchequer twice a year, *viz.* on the laſt day of the two iſſuable terms; but in extraordinary caſes there may be a rule to eſtreat them ſooner. 1 Salk. 45.

Estreats, *Clerk of the.* See Clerk.

ESTREES, Francis-Annibal D', in *Biography*, was born in 1573, and educated for the church, in which he had the biſhopric of Noyon conferred upon him by Henry IV. at a very early age. When he was only twenty-one he reſigned his eccleſiaſtical preferment, on account of the death of his elder brother, and aſſumed the profeſſion of arms, in which he became diſtinguiſhed under the title of the marquis De Coevres. He was embaſſador extraordinary to Switzerland and the princes of Italy, in 1614. He was created marſhal of France in 1626, and in 1630 ſuccoured the duke of Mantua, who was beſieged in his capital. In 1636 he was deputed embaſſador extraordinary to Rome, a character in which he well ſupported the honour and intereſts of his crown in oppoſition to pope Urban VIII., with whom, and the nephews of the haughty pontiff, he was continually involved in quarrels. He was recalled by his own ſovereign, which he conſidered as an affront, and refuſed to appear at court, to give an account of his conduct. He died at Paris in 1670, at the great age of ninety-eight years, highly reſpected by his countrymen. At the deſire of cardinal Richelieu, he drew up "Memoirs of the Regency of Mary de Medicis," which was publiſhed at Paris in 12mo. in the year 1660. "A relation of the Siege of Mantua, in 1620," and "An Account of the Conclave, in which Pope Gregory XV. was choſen in 1621," have alſo been given to the public from his papers. Moreri.

Estrees, Cæsar d', ſon of the preceding, was born in 1628, and being brought up to the church, he was raiſed to the biſhopric of Laon in 1653. He was created cardinal by Clement X. in 1671; and at the death of that pontiff entered the conclave, and managed ſo as to put off the election five weeks, till the arrival of the other French cardinals. He was ſent into Bavaria to negociate the marriage of the dauphin in 1677, and afterwards went to Rome, on other important and difficult buſineſs. He ſupported the rights of the crown, and of the Gallican church in oppoſition to pope Innocent XI., whom he prevented from publiſhing any act infringing on both. He reſided many years at Rome, the ſole reſident on the part of France, and exerted much influence at the election of ſucceeding popes. On his return to France he was rewarded with the rich abbey of St. Germain des Pres, where he died in 1714, in his eighty-ſeventh year, greatly regretted, &c. leaving behind him a high character as a politician. Moreri.

Estrees-*Saint-Denis*, in *Geography*, a ſmall town of France, in the department of the Oiſe, chief place of a canton, in the diſtrict of Compiègne, with a population of 1040 individuals. The canton has a territorial extent of 150 kiliometres, with 20 communes, and 10,325 inhabitants.

ESTREMADURA, *i. e. Extrema Durii*, a province of Portugal, bounded on the north by Beira, on the eaſt and ſouth by Beira and Alentejo, on the weſt by the ocean; lying between 38° and 40° N. lat. and obliquely between 7° 10' and 9° 30' W. long.; being 140 miles from north to ſouth, and 70 in breadth; containing 5,440 ſquare miles, 8 juriſdictions, 400 pariſhes, and 350,760 inhabitants. Several diſtricts of this province are abundantly fertile, yielding grain, wine, oil, and fruits. The whole country is covered with flowers, and the bees produce a great quantity of honey. The manufacture of ſalt affords one of the chief articles of commerce. The principal towns are Liſbon, Leiria, Abrantes, Pombal, Alcobaca, Setuval, Thomar, Santarem, Alanquer, Torres Vedras, Cintra, and Caſcaes; and the chief rivers are the Tagus, or Tajo, and the Sador or Sado, ſometimes called Cadaon and Caldas.

Estremadura, a province of Spain, bounded on the N. by Leon; on the E. by New Caſtile; on the S. by Andaluſia; and on the W. by Portugal; lying between 38° and 40° N. lat.; and between 7° 10' and 4° 40' W. long.: being 140 miles from north to ſouth, and 90 — 1[illegible]0 from weſt to eaſt. This province was formerly a part of Portugal, but being ſeparated from that country, it is ſometimes called Eſtremadura of Caſtile. It is traverſed by the rivers Guadiana and Tajo, which divide it into three equal parts. Interſected by ridges of hills, it abounds in grain, fruits, and excellent paſtures; but good water is ſcarce, and the air in ſummer is exceedingly hot, inſupportable to ſtrangers, but to the natives not inſalubrious. The principal commerce conſiſts of cattle and fine wool; and the hills are covered with oaks, the acorns of which feed large herds of ſwine, that are black. The inhabitants are in general inclined to corpulency; and are conſidered as humane, affable, ſincere, ſtout, and brave. The principal towns are Badajoz, Placentia, Coria, Albuquerque, Caceres, Truxillo, Merida, Montejo, Xeres de los Cavalleros, Ellerena, and Zafra; and the chief rivers are the Guadiana, the Tajo, and the Alagon.

ESTREMERA, a town of Spain, in New Caſtile; 27 miles S.E. of Madrid.

ESTREMOZ, a fortified ill-built town of Portugal, in the province of Alentejo, containing three churches, ſix convents, two hoſpitals, and 6500 inhabitants; pleaſantly ſituated on a riſing ground in a fertile country; 7 leagues N.E of the capital; and famous on account of a victory gained by the Portugueſe over the Caſtilians, in the year 1663. In its vicinity there is excellent marble. The country on the weſt ſide of the town is pleaſant and well cultivated, abounding in orange gardens and laurels; but at ſome diſtance no traces of cultivation appear. This town has a manufacture of beautiful earthenware.

ESTREPAGNI. See Etrepagny.

ESTREPEMENT, in *Law*, an impoveriſhing or making of land barren, by continual plowing and ſowing, without due manuring, reſt, and other huſbandry.

The word is derived from the French *eſtropier*, to maim; or the Latin *extirpare*, to extirpate, root up.

Estrepement is alſo uſed for any waſte, or ſpoil, made by the tenant for life, upon lands or woods, to the prejudice of him in reverſion; as the cutting down of trees, or lopping them farther than the law allows, &c.

Estrepement is alſo a writ which lies in two caſes: the one, by the ſtat. of Glouceſter, 6 E. I. c. 13, when a man having an action depending, as a formedon, writ of right, or the like, ſues to inhibit the tenant from making waſte during the ſuit.

The other is for the demandant, who is adjudged to recover ſeiſin of the land in queſtion; and before execution, for fear of waſte to be made till he can get poſſeſſion, ſues out his writ.

ESTRICH, or Oestrich, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz on the Rhine; 14 miles W. of Mentz.

ESTUCUA, a town of Mexico, in the province of Mechoachan; 58 miles W. of Mechoachan.

ESULA, or Æsulum, in *Ancient Geography*, a town of Italy, ſituated on a mountain, near the Tiber.

Esula, or *Æſula*, in *Botany*, a word ſaid to be of Arabian origin. See Euphorbia *Eſula*, and Apocynum *Venetum*.

ESULÆ Radix, in the *Materia Medica*, the name of a root of a plant of the ſpurge kind, ſometimes uſed in medicine. The root conſiſting of a cortical part, and an inner ſticky one, the bark only is uſed; and ſuch ſhould be choſen as is new dried, and of a reddiſh colour without and within, and ſuch as, when held in the mouth, affords a very diſagreeable taſte, with great acrimony. It is a very violent purge, and has been ſaid to have performed cures in dropſical caſes, when more gentle medicines have proved ineffectual. It is a good method to macerate it a day or two in vinegar before it is uſed.

ESURIS, in *Ancient Geography*, a town of Spain, ſuppoſed to be *Xeres*.

ESUS, or Hesus, in *Mythology*, a deity among the Gauls, to which they ſacrificed after victory whatſoever came alive into their poſſeſſion. They ſometimes ſprinkled the altars of this deity with the blood of their women and children.

ESZEK, in *Geography*, a town of Sclavonia, with a wooden bridge, built by the Turks over the Drave; 48 miles W.N.W. of Peter-Waradin, and 80 N.W. of Belgrade.

ETABLES, a town of France, in the department of the North Coaſts, and diſtrict of St. Brieuc; 2½ leagues N. of St. Brieuc.

ETAIN, or Estain, a ſmall town of France, in the department of the Meuſe, chief place of a canton in the diſtrict of Verdun, 18 miles N.E. of Verdun. It has a population of 2300 individuals, and its canton compriſes 30 communes, with 7125 inhabitants, on a territorial extent of 247½ kiliometres.

ETALLE, a ſmall town of France, in the department of the Forêts, chief place of a canton in the diſtrict of Neufchâteau, with a population of 1080 individuals. Its canton has a territorial extent of 280 kiliometres, and 13 communes, with 9013 inhabitants.

ETAMPES, a ſmall town of France, in the department of Seine and Oiſe, chief place of a diſtrict of the ſame name, with a population of 7786 individuals. It is ſituated on the left bank of the river Juine, at the confluence of two other rivulets, 36 miles E. of Chartres, ; 45 miles N. by E. of Orleans; and 40 miles S. of Paris. N. lat. 48° 25′. The canton contains 14,187 inhabitants, diſperſed in 15 communes, on a territorial extent of 192½ kiliometres.

As chief place of a diſtrict, Etampes has a ſub-prefect, a court of juſtice, and a regiſter office. There are ſome manufactures of hoſiery, woollen, and cotton yarn, and leather. The ſtockings, in particular, are known in the French trade by the name of ſtockings of Beauce, or Bas de Beauce, from the village where the beſt are made.

The ſoil of the diſtrict of Etampes is ſandy: it produces, however, ſome wheat, rye, barley, oats, and hemp. There are a few vineyards and ſome artificial meadows. The diſtrict contains 6 cantons, 111 communes, 1372½ kiliometres, and 58,890 inhabitants.

ETANGS, Les, a town of France, in the department of the Moſelle, and diſtrict of Boulay; 2½ leagues E.N.E. of Metz.

ETAPLES, or Estaples, a ſmall town of France, in the department of the Pas de Calais, chief place of a canton in the diſtrict of Montreuil, with a population of 1360 individuals. It is ſituated at the mouth of the river Canche, which forms a ſmall harbour, 12 miles N.E. of Boulogne, 168 miles N. of Paris. N. lat. 50° 30′ 44″. The canton contains 19 communes, and 7807 inhabitants, on a territorial extent of 232½ kiliometres.

ETAPPE, in *War*, an allowance of proviſions and forage made to the ſoldiers upon march through a kingdom, or province, to or from winter quarters.

Hence, he that contracts with the country, or territory, for furniſhing the troops in their march, is called etappier.

ETARRY, in *Geography*, a town of Hindooſtan, in the country of Bahar; 34 miles S.W. of Arrah.

ETAULIERS, a town of France, in the department of the Gironde, and diſtrict of Bourg; ſeven miles N. of Blaye.

ETASAGGAH, a town of Hindooſtan, in Bahar; 35 miles S.E. of Bahar.

ETAVERAM, a town of Hindooſtan, in the Carnatic; 10 miles E. of Coilpetta.

ETAYA, a circar of Hindooſtan, in the Soubah of Agra, bounded on the N. by Rohilla; on the E. by the circar of Pattan, Canoge an Corah, and on the S.W. by Jumna. Etaya is the capital.

Etaya, a town of Hindooſtan, in the country of Agra, on the N.E. ſide of the Jumnah, 52 miles S.E. of Agra. N. lat. 26° 45′. E. long. 79° 17′.

ETCH, in *Agriculture*, a term ſignifying the ſame thing as erſh. See Ersh.

ETCHAUK, in *Geography*, a town of Bengal, 22 miles N. of Ramgur.

ETCHING, in the *Polite Arts*, an important branch of that ſpecies of engraving which is performed with the view of delivering impreſſions on paper, by means of the rolling-preſs, is the ſuperaddition of the chemical proceſs of corroſion, to the art of drawing through etching-varniſh, (or etching-*ground*, as it is more frequently termed,) on plates of metal; though it has ſometimes been ſucceſsfully performed on other ſubſtances, and particularly on glaſs.

Etching is moſt frequently performed on plates of copper; and (though aqua-tinta be a ſpecies of etching, for which ſee Aqua-tinta) the means commonly employed, are lines drawn with a ſtylus, or ſteel-point, termed an etching-*needle*, which are afterwards corroded by aqua-fortis.

The etching-needle reſembles the dry point (ſee the article Dry-point) in all reſpects, excepting the ſuperior ſharpneſs of the latter, and that it need not be quite ſo long as dry-points are at the firſt. Of theſe needles, the artiſt ſhould provide himſelf with three or four, for etching finer or coarſer lines, of various dimenſions and different degrees of bluntneſs; that for the fineſt or moſt delicate lines being little leſs ſharp than the dry-point. That he may with certainty etch lines of ſimilar ſtrength and depth, where ſuch are required, as in covering a ſurface of an even tint, the extreme point of his needle ſhould be very delicately and gradually rounded off on a leathern ſtrop ſupplied with crocus-martis, or putty-powder.

The practitioner in etching ſhould, moreover, provide himſelf with a ſoft and large camel's-hair bruſh, wherewith occaſionally to ſweep the duſt, and eraſed etching ground, from the ſurface of his work: and an etching-board of from three to ſix inches in breadth, bevelled to an edge on one ſide, ſupported at the ends by ſmall bars of wood about one-third of an inch in thickneſs, and of ſufficient ſpan to ſtand as a bridge over the varniſhed plate, and prevent the engraver's hand from touching and marring his work, ſhould alſo be provided, and the copper-plate, being previouſly prepared, as ſee Copper-plate, he may proceed to lay his etching-ground in the following manner.

The plate is put upon a German ſtove, or chafing-diſh, and heated over the fire; or, if ſmall, is held with a hand-vice, the poliſhed ſide being upwards, and heated with the flame of paper burning under it; when hot, it is rubbed over with etching varniſh (ſuch as is deſcribed in the ſequel of this article) wrapped up in taffety, which ſhould be gently paſſed from one ſide to the other in a right line, ſo as to form ſeveral rows, till the plate is every where moderately covered; then with a *dabber*, formed of cotton, tied up in Perſian ſilk, let every part of the plate be beat gently, while the varniſh is in a fluid ſtate; and in order to give it a fine grain, and that the varniſh may be equally ſpread over the ſurface of the plate, continue to beat it with the dabber, after the plate is taken from the fire, till it attains a ſomewhat harder conſiſtence in cooling; but the uſe of the dabber ſhould be diſcontinued long before the varniſh is cold, leſt it ſhould be made to riſe from the plate.

When the plate is thus uniformly and thinly covered with the varniſh, it muſt be blackened whilſt it is yet warm by a piece of flambeau, or of a large wax-candle, or taper, twiſted together, till ſix or more flames unite in one, which affords a copious ſmoke; diſpatch is of importance, that the varniſh may not grow cold during the operation, which ſhould be performed, if poſſible, at one heating of the plate, for repeated melting of the varniſh does it much damage. Large plates may be ſuſpended from the ceiling of a room by four cords and iron rings, with the varniſhed ſide downwards, for the greater convenience of being blackened. Care ſhould be taken that the flambeau or candles be kept at a proper diſtance from the plate, that the wick may not touch and burn, or otherwiſe impair the varniſh. The varniſh may be made white, if that colour is preferred to black, by grinding white lead in water, and putting it into a glazed earthen diſh, with a little good glue diſſolved, and melting the whole together. This mixture is ſpread with a bruſh or pencil of hog's hairs thinly and evenly on the varniſh laid on the plate and ſmoothed. The colour is then left to dry; if it fixes with difficulty on the varniſh, the compoſition ſhould be mixed with a drop or two of ox-gall.

When the copper-plate is thus varniſhed, and is quite cold, it remains to transfer from paper to the varniſhed plate, the tracing, or outline of the deſign. If the outline be reduced from an oil or water-colour picture or other original of larger dimenſions than the intended etching, and be executed with lead pencil or red chalk upon drawing or writing paper, the method moſt in uſe among Engliſh engravers, is, to take the varniſhed plate and outline to the rolling-preſs printers, and (ſuffering the latter to lie between wetted paper for a quarter of an hour or ſo, that it may become ſufficiently damp for the lead or chalk to be in a certain degree liquified, while the paper is ſufficiently ſoftened to do no injury to the etching ground,) to paſs it through the preſs, the upper roller thereof being ſupplied with blankets in the ſame quantity, and the preſs adjuſted to about the ſame degree of preſſure, as for printing. If this be carefully performed, the outline will appear at once transferred, and reverſed on to, the ſurface of the etching-ground, and the artiſt have nothing to do but to proceed with his etching, By theſe means the trouble both of retracing and *reverſing* (*i. e.* of changing the right hand view of his picture round to the left, and *vice verſâ*, the left to the right, as it would appear if reflected in a looking-glaſs,) is ſaved to the engraver. The method formerly uſed,—which muſt ever be uſed where no rolling preſs is at hand, and which is ſtill believed to be generally practiſed in the other countries of Europe—is, either to trace the outline of the deſign on tranſparent paper, that by ſimply turning the paper it may be ſeen in reverſe, or uſing thin drawing paper for the purpoſe, to render it tranſparent afterwards by means of oil or varniſh. When this is thoroughly dry, a piece of fan, or other very thin, paper, of the ſize of the outline to be traced, muſt be evenly rubbed over on one ſide with powdered red chalk or black lead, and interpoſed between the outline and varniſhed plate, with the chalked or leaded ſide downward, and both outline and tracing paper being ſtretched tight over the varniſhed plate, and faſtened by means of ſmall bits of wax placed along the margin, a blunt etching-needle muſt be carefully paſſed over the ſeveral outlines with a moderate degree of preſſure, which will occaſion ſo much of the powdered lead or chalk to adhere to the ſmoked etching ground, as, when the papers are removed, will exhibit the outline or tracing of the whole deſign in all its correctneſs.

Having proceeded through theſe introductory mechanical preparations, which require care and ſome knowledge of drawing, the engraver's taſk as an artiſt, or man of taſte or genius, properly begins. Who ſhall preſcribe laws to genius?—He may now exerciſe the knowledge he has previouſly ſtored, and call forth his inventive powers. The forms of his objects muſt now be ſeverally drawn, with ſuch taſte and feeling as he may poſſeſs; and his ſhadows, demi-tints, and lights, excepting ſuch as he may prefer to leave to be executed by the graver or dry point, be hatched, by employing lines more cloſe or more open, and preſſing on his needles more lightly or more ſtrongly, as a ſkilful muſician preſſes on the keys of his harpſichord, and as the ſeveral parts of his work may demand, varying his line with the nature of his object.

The characteriſtic, or local advantage of etching, for certain purpoſes, over lines cut with the graver, conſiſts in the unlimited freedom of which this mode of art is ſuſceptible. The etching-needle, meeting little reſiſtance from the varniſh, glides along the ſurface of the plate, and eaſily takes any turn that the taſte of the artiſt may direct, or his hand accompliſh; and hence its peculiar adaptation to the expreſſion of that claſs of objects which artiſts term pictureſque, ſuch as trees, rocks, ruins, cottages, the ſhaggy hair of animals, broken ground, or other rough and irregular ſurfaces.

It has formerly been much diſputed among the curious, whether Germany or Italy had the honour of giving birth to the invention of etching, and with the view of aſcertaining this point, the dates of the impreſſions from the earlieſt etchings by Albert Durer and Parmegiano have been aſſiduouſly ſought for and compared. The writer of the preſent article conceives that ſome portion, at leaſt, of this diſcuſſion and reſearch, might have been ſpared, had the diſputants reflected that etching, originally **Etzen**, is not an Italian but a German word, and how very unlikely it is that an Italian invention ſhould have been denominated by a German word.

Although this art afforded means analogous to the objects themſelves, of drawing and characteriſing all thoſe objects, of which wildneſs and freedom, communicated by ſpontaneous perception and feeling, is the ſoul, yet engraving with the graver had been previouſly invented, and in the beginning of the ſixteenth century impreſſions from ſuch engravings had called forth the admiration of the taſteful. For theſe reaſons, and from the prevalence of thoſe habits, and prejudices of taſte and education, which hang like dark veils about the faculties of man, the extent and variety of energy of which etching was capable were not perceived, and probably are not even yet perceived; the means of engraving, or manual operation of the graver, was miſtaken for the end; and hence a falſe criterion of merit obtained conſiderable influence; connoiſſeurs gravely put on their critical ſpectacles in order to ſee in what degree, and how dexterouſly, the etcher had imitated the clear and clean-cut lines of the graver; juſt as the early printers with the letter preſs, merely endeavoured to imitate M.S. miſſals and bibles, without perceiving the ſuperior degree of perfection of which printing was ſuſceptible. The Sadelers, Le Boſſe, and others run into this egregrious miſtake, and the latter, who wrote a treatiſe on the art of engraving, lays it down as a principle, that the perfection of this mode of engraving conſiſts in the cloſe ſimilitude of etching to the work done by the graving-tool.

That the efforts of the moſt taſteful, bold, and inventive among the engravers of our own country, have largely contributed to diſpel theſe prejudices, will be ſeen towards the cloſe of this article. At preſent we proceed with our account of the proceſs of etching.

The forms of the ſeveral objects of which any given etching may conſiſt, being drawn with requiſite knowledge and care, and the chiaroſcuro, and expreſſion of the textures of the ſeveral ſubſtances introduced into the compoſition, hatched with the degrees of taſte and truth, which the ability of the artiſt may enable him to diſplay, the buſineſs of corroſion, which is technically called *Biting-in*, begins. For this purpoſe a border of ſuch wax as is of a moderate degree of hardneſs when cold, and of a moderate degree of tenacity whilſt warm, muſt be applied round the margin of the plate, in the form of a little wall or rampart, about an inch, or three quarters of an inch in height. This wax may be compoſed of bees' wax, either tempered with common pitch, or with Venice turpentine and tallow, and at one of the corners a gutter, or ſpout, ſhould be formed for pouring the aquafortis conveniently off the plate. The plate being thus bordered, it is uſual further to fortify or ſecure the work againſt the egreſs of the aquafortis whilſt biting, by turpentine-varniſh thickened with lamp-black, and applied with a hair pencil on the margin of the plate, and under the inſide edge of the rampart of wax. This varniſh or compoſition (which is called *ſtop-ground*) being ſufficiently dry, the aquafortis may be poured on the plate.

We are now arrived at a part of the proceſs where experience, combined with chemical knowledge, is the only practical guide on which any thing like ſound reliance may be placed. Yet a few general rules may not be diſpenſed with. The aquafortis may either be pure nitrous acid, diluted with pure water in the proportions of four or five parts water to one of nitrous acid for the more delicate parts of the etching, or it may be the double aquafortis of the ſhops diluted with pure water in the proportions of two to one, or ſometimes of equal parts, according to the degree of ſtrength or delicacy of the fainteſt parts of the work. Of aquafortis thus diluted, but which muſt be gradually ſtrengthened as the work proceeds, let a ſufficient quantity be employed to riſe, when poured on the plate, about half an inch above its ſurface. If all things have been rightly conducted, it will now be ſeen that the menſtruum will ſoon exert its action in thoſe lines or hatches where the artiſt has preſſed hardeſt on his etching-needle, and will gradually begin to corrode the more delicate lines. It may here be proper to obſerve that a feather, or camel's hair bruſh, ſhould be uſed during the biting, to burſt the ſmall bubbles of fixed air which are liberated from the copper, and cleanſe away from the lines the verdigreaſe which is generated during the operation of the aquafortis: by thus moving the aquafortis to and fro on the plate, it will exert its action uniformly over the whole etching.

In about a quarter of an hour, or when the effects of the aquafortis have become viſible in the more tender parts, it may be poured off, the plate waſhed with clean water, and dried by expoſure to the air, ſunſhine, or (which is now more common, becauſe more expeditious) by the operation of a pair of bellows. After trial made by taking off a ſmall portion of the etching-ground with the ſcraper, or a ſmall piece of pointed charcoal, ſuch parts of the etching as are believed to be ſufficiently corroded, muſt be painted over carefully, or *ſtopped-out*, with the compoſition of lamp-black and turpentine varniſh which is mentioned above; and when this is dry, the aquafortis muſt be re-applied, and the biting proceeded with in the ſame manner, till the ſtronger parts are judged to be ſufficiently corroded, the aquafortis being ſtrengthened from time to time according to the judgment of the operator.

To bite-in a large plate will ſometimes occupy ſeveral days, for great judgment and nicety of obſervation are required in gradating the chiaroſcuro, and conſiderable care muſt be exerted in the ſtopping-out. It need ſcarcely be mentioned, that the operator ſhould be as cautious as the neceſſary degree of attention to his work will allow, not to inhale the fumes which ariſe from the mingled copper and aquafortis, which become more and more deleterious, as the biting advances.

When the ſtrongeſt parts are believed to be ſufficiently corroded, and the plate is thoroughly waſhed with water, it may be again placed on the chafing diſh, or German ſtove, till it be ſufficiently warm for the border of wax to be removed, after which, and while it is yet warm, the varniſh may be diluted by the application of a ſmall quantity of oil of turpentine or of olives, and wiped off with a rag; when, if the biting-in hath been ſucceſsfully accompliſhed, the etching is complete, and in ſome caſes the plate is finiſhed; though in moſt caſes it happens that the engraver's taſte and judgment direct him purpoſely to leave certain parts to be finiſhed with the dry point and graver.

For an account of the early progreſs of the art of etching, the reader is referred to our account of the GERMAN and ITALIAN *ſchools* of engraving. Its more recent improvements have taken place in England. In etching trees, which no other mode of engraving can adequately expreſs, Vivares and Pouncy have diſplayed an art of characterizing the ſpecies of tree which it was their object to repreſent, and at the ſame time of ſuggeſting in the varying ſtyles of their foliage, thoſe maſſes or countleſs numbers of leaves which are ſeen in nature itſelf. Their etchings of trees are decidedly ſuperior to thoſe which have been produced on the continent, unleſs we might except the trees of Waterlo and Kobell, and have rarely been equalled by thoſe of the engravers of our own iſland.

He who would ſee the moſt perfect ſpecimens which have been produced of this ſpecies of art, ſhould look at aquafortis proofs (not the finiſhed engravings) which Vivares has produced after Claude, Patel, and Gainſborough; and thoſe which Pouncy has etched after Wilſon, Hearne, and Farington. In looking at the former, he will ſee with ſurpriſe how much Vivares has attained of the peculiar beauty, feeling, and delicacy of Claude's pencil, although he could only have been acquainted with certain pictures:—the larger Colonna Claude for example, from which he has produced a moſt exquiſite etching—through the medium of chalk drawings, and thoſe not very good. It is not leſs worthy of admiration, at leaſt of high approbation, to obſerve how truly Pouncy has characterized the painting of Wilſon, in his etchings of "Athens in Proſperity," and "Athens in Ruin," which are alſo executed from chalk drawings copied from the originals of Wilſon in the library of the late Mr. Willett.

In rocks and cottage ſubjects Browne has ſcarcely been leſs ſucceſsful, as may be ſeen in the aquafortis proofs of the beſt of his large plates after Both, Salvator Roſa, and Du Sart. In the rocks of his "St. John preaching," after Salvator Roſa, he is perhaps ſomewhat extravagant, and out of harmony with his own figures and foliage, though vigorous and characteriſtically rugged; but in "the Cottagers," and "the Jocund Peaſants," after Du Sart, he is unrivalled; the ſeveral textures of the old plaſter walls, old planks, thatch, broken ground, rough coated animals, (though theſe are probably etched by Woollett,) and even the ſluſh which trickles down the hog-trough, are etched with the trueſt feeling of nature and Du Sart.

In etching ruins, as well as more perfect architectural ſubjects, Piraneſi the Roman led the way, and Rooker the elder ſucceſsfully followed. Theſe artiſts more than perhaps any other, except Mr. Lowry, ſhewed the affinity, or ſuſceptibility of pictureſque union, which ſubſiſts in fine art, between freedom of handling and geometrical preciſion; as may be ſeen with pleaſure in the antiquities of Rome and Pæſtum, which Piraneſi etched from his own drawings; (the original and very maſterly drawings of the temples at Pæſtum being preſerved in the collection of Mr. C. Lambert of the Temple F. A. S.) in the ſix large views of London, which Rooker etched after the drawings of P. Sandby and himſelf; and among numerous other works from the hand of Mr. Lowry, in the plate of the weſt door of the cathedral of Carrara from the drawing of Flaxman, as well as in various other plates of architectural and mechanical ſubjects, by which this work is illuſtrated and adorned, and which conſiſt almoſt entirely of etching.

With the view of etching ſubjects of this kind with ſuperior accuracy and facility, Mr. Lowry, about twenty years ſince, invented and began to conſtruct ſeveral inſtruments or machines, which it is within the knowledge of the writer of this article have been much employed on the engravings which are ſpoken of above. The firſt was "for etching ſucceſſive lines either equidiſtant, or in juſt graduation from being wide apart to the neareſt approximation, *ad infinitum;* the compaſs of the inſtrument being commenſurate with the poſſible demands of the art. The ſecond, which is more recently conſtructed, is for ſtriking elliptical, parabolical, and hyperbolical curves, and, in general, all thoſe lines which geometricians call mechanical curves, from the dimenſions of the point of a needle, to an extent of five feet."

Within the laſt ſeven years he has conſtructed other machinery for facilitating particular operations in etching, and enſuring preciſion in deſcribing arches of circles of every poſſible radius; lines converging to points at all diſtances; various kinds of ſpiral lines, and the cogs and ſmaller teeth of wheel work; of the ſeveral uſes and ſuperior powers of which machinery, numerous examples may be ſeen in what has already appeared of this Cyclopædia.

Of theſe inventions it may be truly ſaid that they combine elegance with utility, and are of high value if only conſidered as auxiliaries of the imitative part of this branch of engraving; but as the auxiliaries of chemical, agricultural, and mechanical ſcience, they are of incalculable advantage. The accuracy of their operation, as far as human ſenſe, aided by the magnifying powers of glaſſes, enables us to ſay ſo, is perfect; and it is not neceſſary here to inſiſt on the advantages that muſt reſult to the whole cycle of ſcience, from mathematical accuracy. A hope may be indulged that before the completion of theſe volumes, Mr. Lowry may be induced to favour the public with plates, and particular deſcriptions of his various apparatus.

It now remains to deſcribe the compoſition of the ſeveral kinds of etching-ground, which have been uſed by different engravers from time to time.

Of etching grounds there are three principal kinds, *viz.* common etching ground, hard ground, and ſoft ground.

The hard ground was formerly much uſed, being better accommodated to the intention of imitating the engraving with the tool; but the former has now wholly ſuperſeded the uſe of the other, as it gives a power of expreſſion incompatible with the greater inflexibility of the hard varniſh, which confines the lines and hatches to ſuch a ſameneſs and regularity as give a ſtiffneſs of manner, and coldneſs of effect to the work.

There are various directions for preparing the *common* etching-varniſh, which is by far the moſt in uſe and the moſt worthy of being ſo. Le Boſſe recommends the following: take of virgin wax, very white and clean, and of grains of maſtic very clear and pure, each one ounce; and of calcined aſphaltum, half an ounce: grind the maſtic and aſphaltum ſeparately, very ſmall, and melt the wax over the fire in an earthen pot well glazed. When the wax is thoroughly melted, and very hot, ſprinkle the maſtic into it gradually that it may melt, and ſtir the mixture that the ingredients may incorporate. Then ſprinkle the aſphaltum into the mixture, ſtirring the whole compoſition over the fire till the aſphaltum be entirely melted: take the pot from the fire, and let the mixture cool; and pour the varniſh into clean warm water, and by working it with the hand, form it into a roll of about an inch in diameter, or into ſmall balls, which may be wrapt up in taffety and kept for uſe. The quantity of wax ſhould be increaſed in winter, in order to attemper the varniſh to the exiſting ſtate of the atmoſphere.

The following varniſh is uſed by many of the engravers at Paris: take of virgin wax, and aſphaltum, of each one ounce; half an ounce of black pitch; and a quarter of an ounce of Burgundy pitch: the aſphaltum muſt be pounded in a mortar, and the wax melted over a ſlow fire in a pot of glazed earthen-ware, and the reſt of the ingredients added by little and little, ſtirring the mixture till the whole be well melted and incorporated. Then throw the whole maſs into a veſſel of clean warm water, and proceed as before.

Mr. Lowry's recipe for common etching ground is as follows:—To two ounces of aſphaltum add one of Burgundy-pitch, and an ounce and a half of white virgin wax. The aſphaltum muſt firſt be finely powdered, and then melted in the glazed earthen veſſel over a moderate fire, before the Burgundy pitch is put in: the wax muſt be added laſt, when the whole compoſition muſt be well ſtirred, and then poured into warm water, to be further incorporated by means of the hands, and made up into balls for uſe.

The *hard* varniſh, which was uſed by Callott and other engravers of the continent, and which was commonly called the Florence varniſh, was prepared in the following manner. Take four ounces of fat oil, very clear, and made of good linſeed oil, like that uſed by painters. Heat it in a new pot of glazed earthen ware, and afterward put to it four ounces of grains of maſtic well powdered, and ſtir the mixture briſkly till the whole be well melted together, then filter the whole through a piece of fine linen into a glaſs bottle with a long neck, that can be ſtopt very ſecurely, and keep it for uſe.

In laying this varniſh on the plate, it may be ſpread evenly with the dabber and ſmoked, as before directed, but after it is ſo ſpread, there remains to dry or harden it over the fire, for which purpoſe it will be proper to prepare a charcoal fire which ſhall emit no ſparks; it ſhould be contained in a coal-pan or chafing-diſh, ſomewhat larger than the plate, which ſhould be placed over it for the ſpace of from eight to twelve minutes, every precaution being uſed to prevent duſt from approaching the plate. Whilſt in this ſituation the varniſh will ſoon begin to ſmoke, and when this ſmoking is obſerved to decreaſe, the plate muſt be removed from the fire, and touched at the ſide or on the margin with a little piece of hard wood. If the varniſh be eaſily raiſed by the touch, it is yet too ſoft, and the plate muſt be again placed over the fire as before: after a ſhort time it muſt again be tried with the ſtick, and if the ſtick adhere to the varniſh ſo as to require ſome ſlight effort to draw it away, the plate muſt from that inſtant be left to cool. If on the firſt trial the ſtick adhere ſtrongly to the varniſh, water muſt be immediately thrown on the back of the plate, to cool it as quickly as poſſible, leſt a longer continuance of the heat render it too hard, or burn the varniſh. When the plate is cold, the artiſt may proceed with the tracing and etching, as before directed.

The *ſoft* ground or varniſh is prepared ſimply by mixing common etching ground with animal oil, in proportion of more or leſs according to the exiſting ſtate of the atmoſphere; a much ſmaller portion of the oleaginous ingredient being admiſſible in ſummer than in winter. If common tallow be uſed for the purpoſe, the ſalt which it may contain ſhould firſt be precipitated, by dropping the melted tallow into water, and afterward ſkimming it from the top; but Mr. Gilpin recommends veal ſuet, and it is probably to be preferred.

The method of uſing ſoft ground is as follows. Over a plate thinly covered with this ſort of varniſh, and ſmoked as in the caſe of the common etching ground, the artiſt cautiouſly ſpreads a ſheet of very thin paper, which it is beſt to ſpread in a damp ſtate, and to faſten with ſtrong paſte by the edges, which ſhould be folded over for the purpoſe on the back of the plate: the paper will thus, when dry, be ſtretched tight and flat over the ſurface of the varniſh.

All is now ready for the reception of the etching, which is performed ſimply by making a hatched drawing of the intended ſubject with a black lead pencil on this paper. Great care muſt be taken during the etching that nothing but the pencil touch the paper, and for this purpoſe ſuch a bridge muſt be employed on which to reſt the hand of the artiſt, as is before recommended. When the drawing is complete, the paper muſt be carefully removed from the ſurface of the plate, which muſt be ſurrounded with a rampart of wax, and the aquafortis applied as before directed. This is the whole of the proceſs of etching in ſoft ground. As much of the varniſh as it was neceſſary to remove, in order to admit the aquafortis to the copper, will be found to have adhered to the back of the paper on which the artiſt has been drawing, which, preſuming the plate to be judiciouſly *bit-in*, will exhibit the exact archetype of the impreſſions which the etchings will produce.

It remains to be ſaid of etching in ſoft ground, that the ſtippling with the graver, which it is ſometimes found neceſſary to add in certain parts, after the plate is bit-in, does not incorporate ſo thoroughly with the ſketchy looſeneſs and chalky texture of the etching, but that a judicious eye will always diſcover the junction, and a delicate taſte will dwell on it with the ſame kind of diſſatisfaction that we regard a modern repair of a fine old picture that has been damaged; and further, that though it be a mode of art extremely well calculated to imitate a painter's ſketch or drawing in black-lead or chalk, it is by no means capable of producing a complete abſtract of a finiſhed picture.

There are certain local energies peculiar to every branch of engraving. He who ſhould endeavour in mezzotinto or the chalk manner to rival the playful freedom and characteriſtic taſte which is diſplayed by Vivares in his etchings of trees, would find himſelf as much miſtaken in his aims as he who by etching through ſoft ground, or on *ſtone* (for which ſee ETCHING *on Stone*,) ſhould attempt to render the delicate blandiſhments, ſo as to produce a complete abſtract of the full harmony, of the finiſhed works of Correggio or Claude. On the other hand, either of theſe modes of etching is far more capable of producing a faithful tranſcript of a drawing hatched with chalk or lead-pencil, than the powers of the graver and aquafortis united on copper, and of multiplying ſuch drawings, certainly affords the moſt efficient means.

It may not be ſuperfluous to add that it is not the painter's ſketches that it is moſt deſirable to multiply, but his finiſhed performances; we wiſh moſt to ſee the mercury of his active imagination amalgamated with the ſterling gold of his cultivated underſtanding; and we juſtly value an art of engraving as it is capable of rendering or reproducing the pure forms into which this rich maſs may be moulded.

ETCHING *on Stone*. A method of etching on calcareous ſubſtances, which may be termed a chemical art of multiplying hatched drawings, has alſo been recently diſcovered in England, or recently imported from Germany; and ſome very ſpirited ſketchy etchings have been executed in this way by the preſident Weſt, and Meſſrs Fuſeli, Coſway, Barry, and ſome other members of the Royal Academy. Meſſrs. Corbould, Stubbs, and C. Heath are alſo among thoſe who have ſucceſsfully practiſed this new art.

The materials were ſupplied by a gentleman not now in England: the knowledge of the exact proportions of the ingredients of which they conſiſted, was not imparted to thoſe who made uſe of them, neither is it believed to have been imparted to any one elſe; but the materials themſelves being known, the proportions may preſumptively be aſcertained by a little experience.

The ſtone was of a ſpecies reſembling that fine-grained ſtone of a yellowiſh colour, which is found in large quantities in the neighbourhood of Bath, and is called Bath ſtone. The etchings were of two kinds; thoſe performed with a crayon, and thoſe performed with pen and ink. The crayon was a mixture of white wax and lamp-black, with a ſmall quantity of ſhell-lac. The ink conſiſted of ſhell-lac, borax, and water, and the ſtones which received the crayons were ground to a ſurface ſomewhat leſs ſmooth than thoſe which were prepared for the reception of the ink.

The method of etching is merely *drawing* on the ſtone with theſe materials. The myſtery, or ſecret—which any chemiſt would eaſily develope—reſides in the manner of printing theſe drawings, and is ſimply as follows.

The ink is to be prepared as printer's ink is commonly prepared, namely, ground up with oil, and the paper which is to receive the impreſſion muſt be damped in the uſual manner. The etched ſtone is then to be wetted by immerſion in water; when it is taken out, and while it is ſtill wet, the ink being carefully applied on its ſurface, without violent friction, by means of a printer's ball (ſuch as is uſed in letter-preſs printing) will be found to adhere only where the ſtone has been hatched by the artiſt, with the crayon or ink, the antipathy of oil to water effectually preventing it from ſticking any where elſe. The paper is now to be placed as in letter-preſs printing, and a preſſure, which need not be very violent, applied either by means of a roller paſſed over the back of the paper or otherwiſe: a blanket or finer woollen cloth, being interpoſed between the roller and paper.

Etching *on Glaſs*, is performed in the following manner: Lay a thin coat of white wax (as etching ground is laid) on the plate of glaſs. On this the drawing muſt be traced in the uſual way. When the ſubject is etched, a border or wall of wax of a very even height muſt be put around: take then ſome fluor ſpar powdered to about the fineneſs of oatmeal, and ſtrew it *evenly* over the etching, and on this pour a mixture of equal quantities of ſulphuric acid and water, till the whole is about the conſiſtence of thick cream: a cover of metal or wood muſt then be laid over, and fitted cloſe on the border of wax, to keep in the fumes of the acid, the eſcape of which would ſo weaken the liquor that it would not act on the glaſs, and would beſides be very hurtful to the lungs.

If the ſubject be to be etched with care, and high finiſhing be required, the acid mixture muſt be taken off occaſionally, and the plate, after being well waſhed and dried, muſt have the parts that are bit-in enough, ſtopped-out, as in common etchings, when the mixture muſt be again put on, and cloſed down as before; and this muſt be repeated till the ſeveral gradations of ſhade are believed to be ſufficiently corroded.

Etchings on glaſs are printed by means of the rolling preſs, and it need ſcarcely be added that much care is requiſite on the part of the printer, leſt the plates of glaſs ſhould ſplit in paſſing through the preſs.

ETEA, or **Etia**, in *Ancient Geography*, a ſmall town of the iſle of Crete.

ETELENT, in *Geography*, a town of Aſiatic Turkey, in the Arabian Irak, ſituated on the Tigris; 66 miles N.N.W. of Baſſora.

ETENDUE, *Fr.* in *Muſic*. See Compass.

ETEON, in *Ancient Geography*, a town of Greece, in Bœotia.

ETEONOS, a town of Greece, in Eubœa.

ETERNAL Flower, in *Botany*. See Xeranthemum.

ETERNITY, duration which is conceived incommenſurable with time, and excluſive of beginning, progreſs, ending, &c. See God.

Authors are much at a loſs for a proper and juſt definition of eternity: that of Boethius, De Conſol. Philoſ. lib. v. part 6. *viz.* "Interminabilis vitæ tota ſimul et perfecta poſſeſſio, *i. e.* a perfect poſſeſſion of a whole endleſs exiſtence altogether," though retained by S. Thomas and others, is faulty in divers reſpects.

Cenſorinus, De Die Natal. defines eternity by infinite duration, that is, duration which has always been, and always will be. Others more fully deſcribe it by a duration that exiſts altogether without any flux or ſucceſſion of parts prior or poſterior to each other: where the word duration, taken abſtractedly, imports no more than the perſeverance of a thing in its exiſtence, the τȣ *durare* being here oppoſed to the τȣ *ceſſare, in exiſtendo.*

But ſoften the word duration how you will, it is ſcarcely conceivable but by conceiving a quantity thereof, nor a quantity without conceiving a ſucceſſion. Others, therefore, define eternity by a *perpetuum nunc*, a perpetual now, or a *nunc ſemper ſtans*, an everſtanding now; but neither are theſe unexceptionable, the words *perpetuum* and *ſemper ſtans* importing an obſcure ſort of duration. See Duration.

Eternity, in *Mythology*, a divinity among the Romans, who had neither temples nor altars. They repreſented it under the figure of a woman, who held the ſun in one hand and the moon in the other: her ſymbols were a phœnix, globe, and elephant.

ETERNOZ, in *Geography*, a town of France, in the department of Doubs, and diſtrict of Quingey; 2½ leagues S.E. of Quingey.

ETESIÆ, or **Etesian** *Winds*, are ſuch as blow at ſtated times of the year, from what part ſoever of the compaſs they come. They are ſo called from the Greek word ετος, *year*, being yearly or anniverſary winds, ſuch as our ſeamen call monſoons and trade-winds, which, in ſome parts of the world, continue conſtantly blowing for certain ſtated ſeaſons of the year. Thus the north winds, which, during the dog-days, conſtantly blow upon the coaſts of Egypt, and hinder all ſhips from ſailing out of Alexandria for that ſeaſon, are called eteſiæ in Cæſar's Commentaries. In other authors, the weſt and eaſt winds are called eteſiæ, when they continue blowing for certain ſeaſons of the year. Vide Salmaſ. Exercit. in Solin. p. 421.

Cellarius endeavours to prove that thoſe winds are properly eteſian which blow from that part of the horizon which is between the north and weſt about the time of the ſolſtice. Geog. Antiq. lib. i. cap. 8. See Monsoon and Wind.

ETETA, in *Ancient Geography*, a town of Upper Myſia, according to Ptolemy; called Ægeta in the Itinerary of Antonine.

ETFU, or **Edfou**, in *Geography*, a village of Upper Egypt, ſituated near the Nile, above Eſneh, built on the ruins of the great city of Apollo, or Apollinopolis Magna, and now governed by an Arab ſcheik. It poſſeſſes an ancient temple, covered with hieroglyphics, among which, ſays Savary, we diſtinguiſh men with falcons' heads. Its inhabitants were enemies of the crocodile. The extent, majeſty, and preſervation of this edifice, ſays Denon, who has given a view of it, "ſurpaſſed all that I had ſeen in Egypt, or elſewhere; it made an impreſſion on me as vaſt as its own gigantic dimenſions. This building is a long ſuite of pyramidal gates, of courts decorated with galleries, of porticoes, and of covered naves, conſtructed, not with common ſtones, but entire rocks." "The excellent preſervation of this ancient edifice forms a wonderful contraſt with the grey ruins of modern habitations built within its vaſt incloſure; a part of the population of this village is contained in huts built in the courts, and around the fragments of the temple; which, like ſwallows' neſts in our houſes, defile them without concealing or injuring their general appearance." Below Etfu, the cultivated country becomes very narrow, ſo that there is only a quarter of a league in breadth between the deſert and the river.

ETHAM, in *Ancient Geography*, a town of Egypt, ſituated in the deſert, which gave name to the lower part of the Red ſea, oppoſite to Magdalum. It was the third ſtation of the Iſraelites in their eſcape from Egypt.

ETHELBERT, in *Biography*, king of Kent, ſucceeded to the throne about the year 560. He began his reign with a reſolution to revive the reputation of his family, which had been ſinking in the ſcale of monarchy; with this view he made war upon the king of Weſſex, by whom he was twice defeated, though he was afterwards triumphant, and acquired the complete aſcendancy over Weſſex and the other ſtates, except Northumberland, and reduced them to the condition of his tributaries or dependants. In the reign of Ethelbert, Chriſtianity was introduced into England. The king had married Bertha, daughter of the king of Paris, who being a Chriſtian, had ſtipulated for the free exerciſe of her religion, and had carried over in her train a French biſhop. So exemplary in every reſpect were her life and conduct, that ſhe inſpired the king and his court with a high reſpect for her perſon, and for the religion by which ſhe appeared to be influenced. The pope, taking advantage of this circumſtance, ſent a miſſion of forty monks, at the head of whom was Auguſtine, to preach the goſpel in the iſland. They landed in Kent in 597, and were well and hoſpitably received by Ethelbert, who aſſigned them habitations in the iſle of Thanet. A conference was held, and the king took time to conſider of the new doctrines propounded to him; and in the mean while gave them full liberty to preach to his ſubjects. Numbers were converted, and at length the king ſubmitted to a public baptiſm, Chriſtianity proved the means of promoting knowledge and civilization in this iſland; and the king, with the conſent of his ſtates, enacted a body of laws, which was the firſt written code promulgated by the northern conquerors. Ethelbert died in the year 616, and left his crown, after a reign of 50 years, to his ſon Edbald. Hume's Hiſt of Eng.

ETHELBERT, king of England, was ſon of Ethelwolf, and ſucceeded to the government of the eaſtern part of the kingdom in 857, and in three years afterwards he became ſole king. He died in 866, but had, in the courſe of his reign, ſhewn a conſiderable ſhare of vigour in defending his dominions from the inroads of the Danes, who at that period were cruel enemies to this country, and continued to ravage one part as they were repulſed from another. Hume.

ETHELEUM, in *Geography*, a river of Aſia, which ſeparated between the Troade and Myſia.

ETHELING, or ÆTHELING. See ATHELING.

ETHELRED I., in *Biography*, king of England, ſon of Ethelwolf, ſucceeded his brother in the year 866. The reign of this monarch was ſhort but full of troubles. The Danes had already gained an aſcendancy over the kingdom, and ſeemed now to threaten it with entire conqueſt. The enterpriſing Alfred united his ſkill to the power which his brother the king was able to call forth; they purſued the invaders from place to place, and drove them from the centre of Mercia. The Mercians, careleſs of their liberties, or jealous of the ſuperiority which victory was likely to give to the monarch, refuſed to co-operate with him, and Ethelred was under the neceſſity of oppoſing the Danes with his Weſt Saxons alone. With theſe he was generally ſucceſsful, till large reinforcements were ſent to ſupport the invaders, which enabled them to make a ſtand againſt the natives. The actions fought were frequently very bloody, and in one of them Ethelred was wounded. He died in 871, leaving his crown to the immortal Alfred; of whom we have already ſpoken. Hume's Hiſt.

ETHELRED II. king of England, was ſon of Edgar, and brother to Edward the Martyr, whom he ſucceeded to the crown in the year 978. He was at this period a minor, and from his want of capacity and vigour in the affairs of government he was, in his riper years, characterized by the epithet of "The Unready." No man, however, ſtood more in need of exertion and enterpriſe, for the Danes, who had for ſeveral years forborne all depredations, renewed their attacks with the utmoſt fury; and meeting with little oppoſition, they became more bold, till, at length, in the year 993, under Sweyn king of Denmark, and Olave king of Norway, they made a formal invaſion of the country. At firſt nothing ſeemed to oppoſe the rapidity of their progreſs: and they laid ſiege to London, which was valiantly and ſucceſsfully defended by the citizens. A miſtaken policy in behalf of the Engliſh induced them to purchaſe the departure of the invaders, who, in 997 and 998, returned in large bodies, laid waſte the ſouthern parts of the kingdom, and demanded a ſtill larger bribe than they had before received. To ſtrengthen himſelf by a foreign connection, Ethelred married, in 1001, Emma, ſiſter to Richard II. duke of Normandy. In the following year a dreadful maſſacre took place, on the ſame day throughout England, of all the Danes ſettled in the kingdom. The Engliſh in this inſtance were the willing inſtruments in the hands of the king to execute his bloody orders. They ſpared neither age nor ſex; even a ſiſter of the Daniſh ſovereign, who had married an earl, and had conformed to the Chriſtian profeſſion, was barbarouſly murdered, having already witneſſed the death of her huſband and infant children. Such revenge, ſays the hiſtorian, added nothing to the ſtrength of the nation, but rendered its enemies more implacable. In 1003, Sweyn again invaded the iſland, and carried deſolation all along the Weſtern coaſt. On a ſubſequent occaſion the bold invader obliged the nobles to ſwear allegiance to him as king of England, while Ethelred, in 1013, fled into Normandy with his family. Sweyn maintained his power only a year, when death put an end to his reign, and Ethelred was recalled by his loyal ſubjects. He reſumed the government, but had not learned that wiſdom which his misfortunes were calculated to teach; he ſubmitted to Canute the ſon of Sweyn, whoſe valour and activity he was unable to reſiſt. Ethelred died in 1016, after an inglorious reign of thirty-five years. Hume.

ETHELWOLF, king of England, ſucceeded his father Egbert in the year 838. Little ambitious of government, one of his firſt acts was to give his eldeſt ſon, Athelſtan, the ſovereignty over Eſſex, Kent, and Suſſex. His whole reign was moleſted by the incurſions of the Danes, and about the year 851 they became ſo formidable as to threaten the total ſubverſion of the government. The natives were not inactive, but oppoſed the enemy with the utmoſt vigour; nevertheleſs they took up their winter-quarters in England, and before they returned, burnt Canterbury and London. In the midſt of theſe dangers the king, excited by a ſpirit of devotion, made a pilgrimage to Rome, where he remained about a year, being accompanied by Alfred, who was afterwards king. During his abſence he left his eldeſt ſon Athelſtan as regent, who ſoon after died, and thus afforded an opportunity to his ambitious brother of ſeizing the reins of government with an intention of dethroning his father. To avoid the evil conſequences of civil war the king, without heſitation, ceded the weſtern part of his dominions to his ſon. After this, influenced, in all probability, by the intriguing monks, he ſummoned the eſtates of the whole kingdom, and ſolemnly conferred upon the clergy the tithes of all the produce of the lands. This act of piety, as it was denominated, was conſidered as the moſt effectual meaſure for reſiſting the Danes. Ethelwolf died in 857. Hume.

ETHER, in *Chemiſtry*, is a light, odorant, inflammable liquid, produced by the action of certain of the acids upon alcohol. The acids that have actually been employed for this purpoſe are the ſulphuric, the nitric, the muriatic, the acetic, and the fluoric; whence originate as many ſpecies, or perhaps varieties of ether, all of which we ſhall deſcribe in due order.

§ 1. *Sulphuric ether.*—The method of preparing this ſubſtance is firſt mentioned in the Diſpenſatory of Valerius Cordus, publiſhed about the year 1540; it was alſo known to Baſil Valentine, Paracelſus, and Boyle: it had, however, attracted the notice of chemiſts only in a very imperfect degree, before it was deſcribed by Froben, a German, in the

Philoſophical Tranſactions for 1730. Since that period the preparation and properties of ſulphuric ether have been carefully inveſtigated by many able chemiſts, eſpecially Scheele, Dollfuſs, Macquer, Pelletier, Vauquelin and Fourcroy.

The mode of obtaining ether in the ſmall way is as follows. Take a tubulated glaſs retort, of the capacity of about ſix quarts, lengthen its beak by an adopter, and paſs the other end of the adopter into a two-neck quilled balloon receiver; fix another adopter into the oppoſite neck of the balloon, and join to this a common quilled balloon receiver, placed in ſuch a poſition that the quill, inſtead of pointing directly downwards, as in the firſt receiver, ſhall ſlant gently upwards; then lute all the junctures with linſeed meal or common paſte, except that of the retort to the firſt adopter; fix alſo a 24 ounce vial to the quill of the firſt receiver, and looſely cloſe the quill of the ſecond with a cork or plug of moiſt paper. The lute being moderately dry and hard, withdraw the retort, and pour in through the tubulure 40 ounces by weight of rectified alcohol, and 32 ounces of the ſtrongeſt ſulphuric acid. Replace the retort with its contents, being careful to ſhake it as little as poſſible, and let it remain for 12 hours or more, during which the acid and alcohol will gradually act on each other, producing a conſiderable degree of heat. Afterwards withdraw the retort, and mix together its contents as accurately as poſſible, by communicating to them a gentle circular motion; this being finiſhed, replace the retort, and carefully cloſe by lute its junction with the adopter, and leave the whole in this ſtate till the contents of the retort have acquired a reddiſh-brown colour, which will take place in a day or two. Now proceed to diſtillation, by placing a pot of lighted charcoal beneath the retort, obſerving to heat it very gradually. The firſt impreſſion of the fire drives off a little highly dephlegmated alcohol, but as ſoon as the mixture begins to boil, the ether itſelf paſſes over and condenſes on the ſides of the receiver in large ſtreaks. It is now eſſentially requiſite to keep the receiver as cool as poſſible, by the application of ice or of wet cloths wrung out in cold water and frequently renewed; and if this is properly attended to, by far the greater part of the ether will be condenſed in the firſt receiver, whence it will flow into the vial beneath; a little, however, will paſs through the ſecond adopter into the ſecond receiver, where it muſt be condenſed by the ſame means as have already been recommended. The contents of the retort are to be kept moderately boiling, till ſulphurous acid gas begins to paſs through the quill of the ſecond receiver, which may be known at once by its ſtrong ſuffocating odour. As ſoon as this is perceived, the fire is to be withdrawn, and the vial is to be detached from the receiver, and its contents poured into a ground-ſtoppered bottle; being then replaced as before, the proceſs of diſtillation is to be re-commenced till about ſix or ſeven ounces of a coloured liquid are produced, after which the operation is to be ſtopped. The original mixture of ſulphuric acid and alcohol is thus divided into three ſeparate products; namely, the reſidue in the retort, and the products of the ſecond and firſt diſtillations. In the retort is a black thickiſh matter, ſmelling ſtrongly of ſulphurous and acetous acids, and intenſely ſour to the taſte. If diluted with an equal bulk of warm water and filtered through pounded glaſs or clean white ſand, it will be ſeparated from the carbonaceous matter with which it was loaded, and by ſubſequent boiling the ſulphurous and acetous acids will be driven off, leaving behind ſulphuric acid in a conſiderable degree of concentration, and applicable to a variety of uſeful purpoſes. The product of the ſecond diſtillation conſiſts of two diſtinct liquids, the heavieſt of which is acidulous water, and the lighter an impure ether, called *oil of wine*, which may be ſeparated from the water by inverting the vial that contains them in warm water; a little of the ether is in conſequence converted into elaſtic vapour, which forces out of the vial the lower and heavier fluid. The product of the firſt diſtillation is impure ether, in quantity about 17$\frac{1}{2}$ ounces. Thus from 32 ounces of ſulphuric acid and 40 ounces of alcohol there are procured about 17$\frac{1}{2}$ ounces of impure ether, and three ounces of oil of wine; and the ſulphuric acid that may be recovered, taking into conſideration its quantity and denſity, amounts to about 46 per cent. of that originally employed.

Ether, when freſh diſtilled, is contaminated by ſulphurous and acetous acids and a little coloured oil, in conſequence of which it is neceſſary to purify it by rectification. This is generally done by adding to the ether ſucceſſive portions of cauſtic potaſh or ſoda diſſolved in water, and ſhaking together the two fluids in a well cloſed bottle, after each addition of alkali, till the ſulphurous odour is totally deſtroyed; the contents of the bottle are then to be poured into a retort, and by the application of a gentle heat, never amounting to ebullition, the ether will paſs into the receiver in a ſtate of great purity, leaving behind a watery ſaline liquor covered by a thin film of browniſh-yellow oil. Scheele recommends that the alkali employed in rectification ſhould be diſſolved in alcohol inſtead of water; the advantage of which is that no ſpontaneous ſeparation of the liquors takes place, and therefore the ſulphurous and acetous acids are neutralized and ſeparated with greater certainty. Diſtillation at a gentle heat will readily ſeparate the ether from the other ingredients. A ſtill cheaper and very effectual method of rectifying ether is the following, firſt employed by Mr. Woulfe. "Fill three-fourths of a bottle with the impure ether, add a little water and a portion of ſlacked lime; agitate the bottle with violence, and keep it for ſome time in cold water, before taking out the cork; if the ſmell of the ſulphurous acid be not removed, add a little more lime and agitate a ſecond time. Decant off the ether into a receiver, and diſtil it off." Another very cheap and ingenious proceſs was invented by Pelletier. It conſiſts in adding to the impure ether a little finely pulverized black oxyd of mangaeſe. The mixture being corked up in a bottle, is to be well ſhaken four or five times a day for the ſpace of a week, at the end of which time the ſulphurous acid will have been converted into ſulphuric, and will have combined with the mangaeſe, from which the ether may be poured off without the neceſſity of diſtillation.

By any of the above methods ether is rectified ſufficiently for any purpoſes to which it is uſually applied; but if the greateſt poſſible degree of purity is required, there ſhould be added to the rectified ether ſucceſſive portions of dry, pulverized muriat of lime, till it ceaſes to be diſſolved; from this mixture, by diſtillation with a very gentle heat, and keeping at the ſame time the receiver quite cold by the application of ice, an ether may be procured, probably entirely free from alcohol and water, and of the ſpecific gravity of 0.65.

Rectified ether exhibits the following properties. It is a tranſparent colourleſs liquor, of a peculiar and to moſt perſons an agreeably fragrant odour, and a hot penetrating, and ſomewhat ſuffocating taſte. Its uſual ſpecific gravity, according to Lavoiſier, is $=0.758$. It is volatilizable at a lower temperature, and more rapidly than any other liquid, a conſiderable proportion being loſt, eſpecially in hot weather, by merely pouring it from one vial into another; hence the veſſels in which it is kept ought to be very exactly cloſed, and for further ſecurity are often kept inverted in cold water. It boils at 98° Fahr. under the uſual atmoſpherical preſſure, and at 20° in vacuo.

Owing to the extraordinary rapidity with which ether evaporates, it poſſeſſes a very great power of refrigeration. This is made obvious to the feeling by pouring a little into the palm of the hand; it is almoſt inſtantly volatilized, and the hand becomes painfully cold. So alſo if ſome fine tow is wrapped about the bulb of a ſmall thermometer, and the blaſt from a pair of double bellows is let upon it, after it has been well ſoaked in ether, the mercury in the thermometer will, in the ſpace of a minute or leſs, be lowered to 0° Fahr. Ether, notwithſtanding its ready volatility, is capable of being congealed at a low temperature. If a ſmall matraſs filled with this fluid is cooled down to −25° Fahr. by a mixture of ſnow and muriat of lime, the liquor becomes gradually filled with brilliant tranſparent cryſtalline laminæ, reſembling benzoic acid or oxymuriat of potaſh; and preſently, eſpecially at a ſomewhat lower temperature, the whole is congealed into a white almoſt inodorous maſs. Ether is remarkably inflammable, taking fire inſtantly on the near approach of an ignited body; it burns with a large white flame and a little ſmoke, and is reſolved into water, carbonic acid, and a minute quantity of charcoal. When paſſed through a red-hot earthenware tube, it is entirely decompoſed, and a large production of carburetted hydrogen takes place. Ether remarkably increaſes the bulk of any of the permanent gaſſes to which it was added, as was firſt obſerved by Dr. Prieſtley. A ſmall quantity of this fluid being mixed with oxygen confined over mercury, exactly doubled its bulk, nor could any additional quantity occaſion a further dilatation. Nearly the ſame effect took place with atmoſpheric air, azot, hydrogen, nitrous gas, and carbonic acid; but by a ſlight agitation in water the ether was abſorbed, and the gas reſumed its former dimenſions without any alteration of its original properties. If oxygen gas thus diluted by ether is ſet fire to, it burns rapidly, but does not explode; but if one part of this mixture is added to three parts of oxygen, the application of an ignited body, or of the electric ſpark, cauſes a violent exploſion, the products of which are water and $2\frac{1}{3}$ parts of carbonic acid. Hence it appears that one part of ether requires 6.8 of oxygen for its ſaturation, and that the proportion of carbon to hydrogen in ſulphuric ether is nearly as 5 to 1.

Water and ether appear to combine with each other in two different proportions. If equal parts of theſe fluids are ſhaken together in a graduated tube, the ether will be found to have diminiſhed in bulk about $\frac{2}{10}$, and the water to have enlarged in nearly the ſame proportion; the lower fluid conſiſts of water ſaturated with ether, and the upper fluid is ether combined with a little water. The ether in this ſtate is ſaid to be *waſhed*, and acquires in conſequence ſome properties which pure ether does not poſſeſs; in particular, it is now capable of diſſolving caoutchouc with great eaſe, whereas this ſubſtance is acted on by pure ether only in a very imperfect manner. Phoſphorus is ſoluble in ether, but the ſolution is not luminous. When ether is boiled with phoſphorus, it often depoſits cryſtals by cooling; agitation with water produces no change in this liquid, but the addition of a little alcohol cauſes an immediate turbidneſs, whence the ſophiſtication of ether by alcohol may be detected by the addition of a few drops of phoſphorized ether. The fixed alkalies ſeem incapable of uniting with ether, but ammoniacal gas is abſorbed by it very copiouſly. The ſame may be obſerved of nitrous gas; but neither of theſe combinations has hitherto been ſubmitted to an accurate examination. Sulphuric acid acts on ether with conſiderable energy, eſpecially if aſſiſted by a gentle heat; it is converted into a browniſh oily fluid, much heavier than ether, called oil of wine, and at a higher temperature is changed into olefiant gas. With regard to the action of oxymuriatic acid on ether, a curious experiment is related by Mr. Cruickſhank. "If we fill a bottle of the capacity of three or four pints with the pure oxymuriatic acid gas, taking care to expel the water as completely as poſſible, and then throw into it about a drachm or half a drachm of good ether, covering its mouth immediately with a piece of light wood or paper, in a few ſeconds white vapour will be perceived, moving circularly in the bottle; this will ſoon be followed by an exploſion, accompanied by flame, at the ſame time a very conſiderable quantity of carbon will be depoſited, and the bottle will be found to contain carbonic acid gas." Nitric acid excites a conſiderable efferveſcence in ether, and ſeems to convert it into oil of wine. The eſſential oils are ſoluble in ether, and it combines with alcohol in almoſt all proportions.

Concerning the theory of etherification, much has been written, and many experiments have been made by able chemiſts, without, however, obtaining the ſatisfaction that could be wiſhed. According to Macquer, ether is a ſubſtance intermediate between alcohol and oil, and alcohol approaches to the ſtate of oil preciſely in proportion as it parts with its water of compoſition. But though it is true that the production of water accompanies the converſion of alchohol into ether, and of ether into oil of wine, yet this is by no means the only phenomenon, ſo that the theory of Macquer is, at beſt, imperfect, ſince the depoſition of charcoal, and the generation of acetous acid, are not at all accounted for. According to Pelletier, Chaptal, and others, the whole proceſs of etherification conſiſts in a transfer of oxygen from the ſulphuric acid to the alcohol: the diſengagement of ſulphurous acid accompanies the production of ether, and therefore ſhews that the ſulphuric acid is deoxygenated: the oxygen, thus ſeparated, does not come over in the ſtate of gas, and therefore muſt be combined with the alcohol forming ether. But in reply, it may be obſerved, that this mode of explanation accounts for only a few of the phenomena, and that the preparation of ether, if carefully managed, may be carried on without the diſengagement of any ſulphurous acid. The moſt elaborate enquiry into this intricate ſubject was undertaken by Vauquelin and Fourcroy, which we ſhall now proceed to detail, though it is by no means ſo complete and ſatisfactory as to preclude the neceſſity of further reſearches. The facts and obſervations by which this theory is ſupported are the following.

If one part of alcohol and two of ſulphuric acid are mixed together, the temperature riſes to about 200° Fahr.; the maſs immediately acquires a deep browniſh-red colour, which deepens into black in a few days after, and at the ſame time exhales a vapour manifeſtly ethereous.

Equal parts of concentrated ſulphuric acid and rectified alcohol acquire on mixture a temperature of 190° Fahr.; bubbles of gas are extricated, the liquor becomes turbid and opaleſcent, and at the end of a few days acquires a deep red colour. The whole being then transferred to a diſtillatory pneumatic apparatus, and being heated to 107° Fahr., ebullition takes place, and ether paſſes over into the recipient; if the operation is carefully conducted no elaſtic fluid is diſengaged, and the vapour, when condenſed, is found to be only water and ether. When the liquor thus obtained amounts to about half of the alcohol employed, ſulphurous acid begins to be manifeſt, and, in a ſhort time, the production of ether ceaſes, and is ſucceeded by oil of wine, accompanied by acetous acid. The contents of the retort being kept boiling, and becoming more and more concentrated as the diſtillation proceeds, are conſtantly acquiring a higher temperature; when this amounts to about 234° Fahr., olefiant gas begins to come over, and continues till the oil of wine ceaſes to flow. At this period carbonic acid gas firſt makes its appearance, and water and ſulphurous acid ſtill continue to be produced, the reſidue in the retort being in the mean time reduced to little elſe than ſulphuric acid thickened by charcoal.

From theſe facts the able chemiſts who obſerved them have concluded,

1. That the ſpontaneous action of alcohol and ſulphuric acid, when this latter is conſiderably in exceſs, is ſufficient for the formation of ether without the aſſiſtance of any extraneous heat, and that by duly proportioning the two ſubſtances, the alcohol might be wholly decompoſed and made to yield all the ether of which it is capable when treated in the uſual manner.

2. That the formation of ether is not owing to the affinity of the oxygen of the ſulphuric acid, for the hydrogen and carbon of the alcohol, becauſe in the preparation of ether no ſulphurous acid gas is evolved till the production of ether has almoſt ceaſed. It muſt therefore be the entire attraction of the acid for one or more of the elements of the alcohol that determines its decompoſition: now ſince water is formed during the whole proceſs, and, ſince the attraction of ſulphuric acid for this ſubſtance is very powerful, it appears likely that this is the cauſe that deſtroys the equilibrium of the affinities by which the elementary particles of alcohol are retained in combination, and induces the oxygen and hydrogen to unite and form water. Hence it might at firſt ſight be ſuppoſed that ether differs from alcohol in containing a ſmaller proportion of oxygen and hydrogen. This however will not be found to be the caſe, when we advert to the depoſition of charcoal, which, equally with the production of water, accompanies the formation of ether: now the amount of charcoal depoſited is greater in proportion to that which is left, than the hydrogen of the water compared to what remains in the ether; therefore this latter fluid, though compoſed of the ſame elements as alcohol, differs from it in containing a ſmaller proportion of carbon compared with the hydrogen. During the progreſs of diſtillation the heat to which the materials in the retort are expoſed is conſtantly increaſing, and (the affinity of the acid and alcohol alſo augmenting) the acid itſelf is at length decompoſed, ſulphurous acid is generated, and the exceſs of oxygen deprives the alcohol of part of its hydrogen whence reſults the oil of wine, differing from ether in containing a larger proportion of carbon; and in confirmation of this, it may be obſerved, that the charcoal depoſited during the production of oil of wine is not ſo abundant as during the generation of ether.

Hence as (according to the authors of the above hypotheſis) no decompoſition of the ſulphuric acid takes place during the formation of ether, the agency of the acid is partly that of detaining the alcohol in a temperature more than ſufficient for the volatilization of this fluid when uncombined, and partly that of aſſiſting the caloric to decompoſe the alcohol in conſequence of its own powerful affinity for water.

A circumſtance, however, firſt remarked by Scheele, but which has hitherto failed to obtain the notice to which it is ſo well entitled, ſufficiently proves that in the formation of ether the acid employed acts a much more important part than is aſſigned to it in the theory of Vauquelin and Fourcroy. The admirable chemiſt above-mentioned ſtates that if ſulphuric ether be duly rectified by agitation with cauſtic alkali and ſubſequent diſtillation, it occaſions no precipitate with barytic ſalts; but if to the ether thus purified there be added nitric acid, a copious precipitate is then produced by any of the ſoluble ſalts of barytes, indicating the preſence of ſulphuric acid. This fact ſtrikingly points out that a portion of the baſe of the acid in a more or leſs deoxygenated ſtate actually combines with the alcohol to compoſe ether. A like fact reſpecting muriatic ether is alſo mentioned by Scheele, namely, that though this ether, when rectified, occaſions no decompoſition of nitrated ſilver, yet the watery reſidue, after combuſtion of the ether, occaſions a copious precipitate of muriated ſilver when mixed with the nitrat of this metal.

§ 2. *Nitrous ether.*—Although nitrous ether appears to have been known to Baſil Valentine and Kunkel, yet the mode of its preparation being kept a ſecret, it ſoon ceaſed to be attended to by chemiſts, till in the year 1740 it was re-diſcovered by Duhamel, and afterwards was more particularly deſcribed by Navier, Sebaſtiani and others. It was prepared by Navier in the following manner. Put 12 ounces of rectified alcohol into a ſtrong bottle, and add to it gradually and at intervals 8 ounces of ſtrong nitric acid; after each portion of acid the liquors are to be well mixed by agitation, and the bottle is to be kept cloſe corked and immerſed up to its neck in ice and water; when the whole of the acid has been added, the bottle is to be well corked and further ſecured by a leathern cap. A ſtratum of ether riſes by degrees to the ſurface of the liquor, and after five or ſix days the cork is to be pierced by a needle in order to let out the nitrous gas formed during the proceſs: this gas having eſcaped, the cork is to be drawn, and the whole contents of the bottle being poured into a ſeparatory funnel, the ether is thus procured unmixed with the heavier fluid on which it floats. This is, however, a very rude way of proceeding, and is attended with the utmoſt riſk to the apparatus, the ether obtained alſo is in ſmall quantity, and very impure. In order to prevent the violent and rapid action of the concentrated acid on the alcohol, which is the chief difficulty in the preparation of nitrous ether, Dr. Black propoſed to interpoſe a thin ſtratum of pure water, and Fiſcher on the ſame principle made uſe of a little weak ſpirit of nitre for the ſame purpoſe. M. Dolfuſs, from a careful repetition of the latter proceſs, obtained the following reſult. Upon two ounces of very ſtrong nitric acid he poured gently ſix drachms of the ſame very much diluted, and upon this three ounces of rectified alcohol. The bottle was looſely corked and ſuffered to ſtand undiſturbed for three days; at this time the lower liquor appeared perfectly homogeneous with a ſtratum of ether floating above it. The whole being put into a retort and ſubjected to a gentle heat, there were obtained two ounces and a drachm of very pure ether unmixed with any acid, and the reſidue in the retort conſiſted of weak acetous acid mixed with oxalic acid, nearly the whole of the nitrous acid having been decompoſed.

The laſt mode by which nitrous ether may be prepared, that we ſhall mention, and which on the whole appears to be the beſt, conſiſts in mixing together alcohol and ſulphuric acid, and pouring the liquor upon pulverized nitre; the ſulphuric acid diſengages the nitre, which immediately re-acts on the alcohol, and ether is the reſult. The able chemiſt whom we have already mentioned has ſhewn the excellence of this method by the following experiment. Having put into a retort four ounces of perfectly dry and pulverized nitre, he added to it a mixture conſiſting of two ounces of concentrated ſulphuric acid, and four ounces of alcohol. The whole being ſubmitted to diſtillation, there came over firſt ſix drachms of dulcified ſpirit of nitre, and then three ounces of a liquor from which by ſubſequent rectification were procured two ounces of pure ether.

Nitrous ether, when recently made, contains in looſe combination a conſiderable quantity of nitrous gas, which in ſome degree modifies its properties, and renders it peculiarly liable to burſt the bottles in which it is kept, eſpecially in warm weather. This loſs and trouble, however, may be avoided by rectifying the ether, which is beſt done in the following way. Pour into a ſtrong vial ſo as to fill it two thirds, one part of ether and four parts of pump-water, and agitate it cautiouſly at firſt, frequently removing the thumb from the mouth of the vial in order to afford a free paſſage to the diſengaged nitrous gas: when no more of this gas is given out add a quantity of dry pearlaſh equal in weight to the ether, and ſhake the whole well together; then put the mixture into a tubulated retort and proceed to diſtillation, taking care that the temperature does not exceed 120° Fahr.; the ether will paſs into the receiver quite pure, and may be kept for any length of time in ſtrong well cloſed bottles, with no more riſk of accidents than ſulphuric ether is ſubject to.

Nitrous ether reſembles ſulphuric ether in moſt of its properties; it has, however, a dilute yellow colour, and a ſomewhat different odour and flavour; this appears to be owing to the preſence of a little reſinous matter, from which it can never be entirely freed; by repeated diſtillations from freſh parcels of dry white ſugar, as Deyeux has obſerved, this impurity may, in great part, be ſeparated, and in proportion as this takes place the ether becomes more and more analogous to that prepared by ſulphuric acid.

Nitrous ether appears capable of uniting with nitrous gas in two proportions; when the ether is in exceſs it forms nitrous ether in the ſtate in which it appears previous to rectification; when the nitrous gas exceeds the ether it forms a permanently elaſtic fluid that has obtained the name of *etherized nitrous gas*. The preparation of this differs only in the rapidity with which the nitrous acid and alcohol are made to act on each other: when the combination takes place very ſlowly much ether and little etherized gas are the reſult, but when the contrary is the caſe, theſe two products are formed in an inverſe proportion. If equal parts of alcohol and ſtrong nitrous acid are mixed together at the common atmoſpheric temperature, or at a higher heat in proportion as the acid is diluted, a very rapid and copious efferveſcence takes place, a little ether is condenſed in the receiver, and a large quantity of gas paſſes through the conducting tube, the firſt portions of which are etherized nitrous gas, and the latter common nitrous gas. What remains in the retort is acetic acid with a little oxalic acid. The properties of etherized nitrous gas (according to Van Diemen and his aſſociates, to whom we are inbebted for its diſcovery) are the following. It has a diſagreeable ethereal odour, exactly reſembling that of olefiant gas when treated with oxymuriatic acid. By the application of flame it takes fire and burns with a yellowiſh lambent flame like alcohol; after the combuſtion has ceaſed, the veſſel in which it was carried on contains a vapour of ſingular pungency. Water abſorbs this gas, but requires a conſiderable time to effect this, except agitation is had recourſe to, reſembling, in this reſpect, carbonic acid. Alcohol produces the ſame effect as water, and takes up the gas not only more rapidly, but alſo in larger proportion. A ſolution of cauſtic potaſh alſo diſſolves it, but with conſiderable difficulty, and on the addition of ſulphuric or muriatic acids the etherized gas is again ſet at liberty unaltered in any of its properties. Ammonia, whether liquid or in the gaſeous ſtate, is incapable of contracting any union with it; the ſame is the caſe with oxygen gas at the common temperature, but a mixture of the two airs, when inflamed, produces a moſt violent exploſion; ſulphuric acid immediately decompoſes this gas, by abſorbing the ether, the nitrous gas retaining its elaſtic ſtate. Sulphurous acid produces the ſame effect, only it requires ſome days for this purpoſe. If ſulphuric acid, previouſly diluted with an equal weight of water, is placed in contact with this gas over mercury, its action is greatly retarded, the diminution of volume in the incloſed air takes place much more ſlowly, and even after ſome days a portion of ether is retained by the nitrous gas, which in conſequence acquires the property of enlarging the flame of a taper that is immerſed in it, in the ſame manner as nitrous oxyd does. Nitrous acid, according to the degree of its concentration, abſorbs either wholly or in part, the ethereous portions of the gas, and the ſame may be obſerved of muriatic acid.

Etherized nitrous gas, when paſſed through a red-hot tube, depoſits a little oil, and by ſubſequent waſhing in lime-water is freed from ſome carbonic acid; the reſidue is nitrous gas, mixed or combined with common carburetted hydrogen, and is not acted on by the ſulphuric, nitric, or muriatic acids, by cauſtic potaſh or alcohol. The addition of oxygen gas produces red vapours, the nitrous gas is converted into acid, and the gaſeous reſidue is carburetted hydrogen.

§ 3 *Muriatic ether.*—After chemiſts had ſhewn the production of ether by means of the ſulphuric and nitric acids, it was natural to attempt its preparation by the muriatic acid. But this latter, in its uſual ſtate of dilution with water, has no action on alcohol, and therefore the various modes that were firſt practiſed to obtain muriatic ether entirely failed. A few chemiſts were ſaid to have ſucceeded by employing ſimple muriatic acid, but in a more concentrated and dry ſtate than the common liquid acid; the proceſs, however, was both difficult and doubtful, and muriatic ether can hardly be ſaid to have been known till Rouelle diſcovered that it might be prepared by diſtilling together alcohol and the ſmoking liquor of Libavius, which is a concentrated muriat of tin in its higheſt ſtate of oxydation. The marquis de Courtanvaux, having repeated the proceſs of Rouelle with great care, propoſes the following as the beſt method of making the ſubſtance in queſtion. Mix together in a retort three parts of the fuming muriat of tin and one of alcohol; a conſiderable degree of heat is immediately excited, and a white ſuffocating vapour ariſes, which, however, ſoon diſappears on agitating the mixture. As ſoon as an ethereous odour is perceived, let two balloon receivers be luted on, and kept as cool as poſſible; then by the application of a gentle heat to the retort there comes over firſt a little dephlegmated alcohol, which is ſucceeded by the ether: by an increaſe of temperature a few drops of coloured oil are produced, and there ariſes, partly in the form of a ſoft butter and partly in that of a denſe brown liquid, a quantity of ſmoking muriat of tin, part of the metallic oxyd remaining in the retort as a grey powder. When the ether thus procured is mixed with pearlaſh, a copious efferveſcence and precipitation take place, owing to the decompoſition of ſome muriat of tin contained in the ether; after which, by diſtillation at a gentle heat, the ether ariſes in a ſtate of great purity, amounting to half the impure product of the firſt diſtillation.

Several other of the metallic muriats have been found to be equally efficacious with the liquor of Libavius; the corroſive muriats of antimony and of arſenic, the muriats of biſmuth and zinc, and the red muriat of iron, have in particular been uſed with ſucceſs in the preparation of muriatic ether. Scheele.

Scheele, the diſcoverer of oxymuriatic acid, was induced to try the effect of this in the preparation of muriatic ether. For this purpoſe he put three ounces of alcohol into a receiver, with which was connected a retort holding two ounces of common ſalt, upon which was poured an equal weight of ſulphuric acid; the muriatic acid thus diſengaged paſſed into the receiver, where it combined with the alcohol; and this, when ſaturated with acid, was transferred to another retort, containing three ounces of black oxyd of manganeſe in fine powder; the mixture inſtantly aſſumed a green colour, and preſently after became ſo hot as to boil. When the ebullition had ceaſed, there was found in the receiver a liquor, from which, on mixture with water, a quantity of ether immediately ſeparated. The ſame method is recommended by Van Mons, except that he employs only one fourth of the manganeſe uſed by Scheele, and performs the ſecond diſtillation in a Woulfe's apparatus, the bottles of which contain a ſolution of cauſtic potaſh, by which the acid is prevented from re-acting on the ether.

Another mode of applying oxymuriatic acid to the preparation of ether, firſt practiſed by Scheele, is mentioned by Pelletier, and deſerves to be repeated, as being perhaps the moſt expeditious and economical of any. He introduced into a large tubulated retort a mixture of eight ounces of manganeſe, and 16 ounces of decrepitated common ſalt, upon which he poured a mixture of 12 ounces of ſulphuric acid, and eight ounces of alcohol. From this maſs ten ounces were drawn off by diſtillation at a gentle heat, which, by ſubſequent rectification, yielded four ounces of ether.

It deſerves to be remarked, that the ether prepared by oxymuriatic acid generally depoſits, during its rectification with potaſh, a conſiderable quantity of a clear aromatic and bitter oil, which ſinks in drops to the bottom of the veſſel; the ether alſo, according to Dollfuſs, at leaſt before rectification, is compleatly miſcible with water when ſhaken with it for ſome time. The preparation of ether, by means of ſimple muriatic acid, is not eaſy, and was readily ſuppoſed to be impoſſible by ſome of the leaders of the modern ſchool of French chemiſts, becauſe it contradicted one of their early theories on the proceſs of etherification; yet Beaumé, a chemiſt of great experience and unqueſtioned veracity, had affirmed, that he had obtained a ſmall quantity of ether, by mixing together alcohol and muriatic acid, both of them in the ſtate of vapour. The practicability of this method appears alſo to be eſtabliſhed beyond doubt by the following formula of M. Baſſe. Keep a quantity of common ſalt in fuſion for about an hour, in order to drive off all the water of cryſtallization, then pulverize it, and put 40 parts into a tubulated retort, connected with a Woulfe's apparatus, in the firſt bottle of which are to be poured 20 parts of moſt highly rectified alcohol; then add to the ſalt in the retort 20 parts of the ſtrongeſt ſulphuric acid, and proceed to diſtillation by a gentle heat, keeping the bottle holding the alcohol as cool as poſſible. When the alcohol is ſaturated with acid, transfer it to a retort, and diſtil over about one half of it; agitate this portion with an alkaline ley, and the ether will preſently ſeparate and float on the ſurface, whence it may be obtained by decantation or diſtillation. The quantity of ether from the above materials amounts to about five parts.

Muriatic ether has a ſtriking reſemblance to that prepared by ſulphuric acid; its ſpecific gravity, however, is greater, amounting, according to Hermbſtadt, to 0.84; its taſte alſo has a peculiar aſtringency like alum, and when burning it exhales a ſtrong acrid odour, ſomewhat reſembling that of ſulphurous acid.

§ 4. *Fluoric ether.*—All that we know of this ſubſtance is derived from the diſcoveries of Scheele. He firſt impregnated rectified alcohol with fluoric acid gas, by diſtilling pulverized fluor ſpar with ſulphuric acid, and placing alcohol in the receiver; the ſmoking ſpirit thus obtained was diſtilled with a gentle heat, but no ſign of ether made its appearance. Another portion of the acidulated ſpirit was then mixed with black oxyd of manganeſe, and by ſubſequent diſtillation an ethereous fluid came over, from which, by ſubſequent rectification, a little ether was obtained of a very agreeable odour, reſembling nitrous ether.

§ 5. *Acetic ether.*—Acetic ether was firſt diſcovered by the Count de Lauraguais; the method of its preparation was by diſtilling together equal parts of alcohol and acetic acid. Scheele, Porner, Bergman, and other chemiſts, repeated this proceſs ineffectually, and hence were induced to ſuſpect ſome error. In conſequence of theſe doubts, Pelletier entered into a careful examination of the ſubject, and has both ſhewn the reaſon of the failure of Scheele, and has given the proper method by which to ſucceed. He diſtilled together equal parts of alcohol and acetic acid, and drew off a little more than half; this liquor was acidulous, and had an ethereal odour, but no true ether could be made to ſeparate. He then mixed together 12 ounces of ſtrong radical vinegar, and the ſame quantity of alcohol, and diſtilled over one half of it at a boiling temperature; this product he poured back into the retort and recommenced the diſtillation; the produce of this and of a third diſtillation were in like manner recohobated, and having diſtilled the whole again for the fourth time, he finally obtained 12 ounces of an ethereous fluid; with this he mixed a quantity of carbonated potaſh, ſufficient to ſaturate the acid which it contained, and then ſubmitted it to gentle diſtillation. The firſt ſix ounces that came over were pure acetous ether, the next four ounces alſo contained ether, but not ſo pure as the former. It is remarkable that during the cohobations a conſiderable abſorption of air took place.

Scheele obtained acetous ether in a much more compendious manner, by mixing together acetat of potaſh, or of lead, or of copper, with alcohol, and then adding as much ſulphuric acid as was requiſite to decompoſe the acetous ſalt, and diſtilling the mixture at a low heat. The produce being ſhaken with water, the ether riſes to the ſurface and may be poured off. From 16 parts acetat of lead, ſix parts ſtrong ſulphuric acid, and nine parts of water, Bucholz obtained ſix parts rectified ether.

Acetic ether always retains the odour of the acid by which it is formed; it is not ſo volatile as the ethers procured by the mineral acids; it burns with a lambent blue flame, like alcohol; it is ſoluble in a little more than twice its bulk of water, and is decompoſable into acetous acid by repeated diſtillations at a very gentle heat.

Various other acids have been diſtilled with alcohol for the purpoſe of procuring ether, but with little or no ſucceſs. Oxalic acid, with an equal weight of alcohol, yielded Bergman a watery ſomewhat etherized alcohol. Benzoic acid and alcohol, according to Scheele, afford no ether, but when a little common muriatic acid is added to the mixture, an ethereous liquor comes over, of which part floats on water and part ſinks in the ſame fluid. The ether, or the lighter portion, has the odour of benzoic acid, burns with a clear flame and ſmoke, and is about equal in volatility to acetic ether. The phoſphoric, boracic, tartarous, citric and ſuccinic acids, were found by the ſame able chemiſt to be incapable of producing ether, either by their own action on alcohol, or when mixed with oxyd of manganeſe or muriatic acid.

ETHER, in *Ancient Geography*, a town of Paleſtine, in the tribe of Juda, which afterwards was aſſigned to the tribe of Simeon.

ETHEREAL Oil. See Oil, *volatile* or *eſſential.*

ETHEREGE, George, in *Biography*, chiefly known as a writer of comedy, was born in the vicinity of London about the year 1636. Little is known of his early years, but it is ſuppoſed he was educated at Cambridge; ſpent ſome time in foreign travel, and afterwards entered himſelf at one of the inns of court. His talents were but ill adapted to the laborious profeſſion of the law; he was fond of gay and polite company, and became a writer for the ſtage. In 1664, his firſt comedy, entitled "The Comical Revenge, or Love in a Tub," was preſented to the town, and well received. The author was immediately enrolled among the wits of the age. His next piece is thought to have been entitled to more praiſe for wit than for morality. It is entitled "She would if ſhe could;" its licentious tendency was juſtly reprobated by the "Spectator," who ſays he knew of but one author who had profeſſedly written a play upon the deſire of multiplying our ſpecies, and that is the polite ſir George Etherege in the play of "She would if ſhe could:" "Other poets," he adds, "have here and there given an intimation, that there is this deſign under all the diſguiſes and affectations which a lady may put on, but no author except this has made ſure work of it, and put the imaginations of his audience upon this one purpoſe, from the beginning to the end of the comedy." His next piece was not produced till the year 1676; it was entitled "The man of the mode, or ſir Fopling Flutter," and dedicated to the ſecond ducheſs of York, Mary of Modena. It was very popular, and regarded as a true model of polite comedy; one of its principal characters was ſaid to be a repreſentative of the earl of Rocheſter, the finiſhed fine gentleman and man of pleaſure. Etherege lived a diſſipated life, and in a few years injured his fortune and conſtitution. With a view of maintaining his rank in ſociety, he paid his addreſſes to a lady of conſiderable fortune, who refuſed to marry him, unleſs he could procure the honour of knighthood. This he readily obtained, and upon the acceſſion of James II. he was ſent out envoy to Ratiſbon, where he reſided ſome time, and from whence he wrote letters which are favourable ſpecimens of his talent for eaſy pleaſantry. He died ſoon after the revolution, but the account of the time and manner of his death has been differently related. By ſome he is ſuppoſed to have died in his native country ſoon after his return from France, whither he had been on public buſineſs, and by others it is ſaid, that it happened at Ratiſbon by a fall down ſtairs. Beſides the comedies already mentioned, Etherege was author of many ſmaller poems. His letters to the duke of Buckingham are in the Biographia Britannica, to which the reader is referred.

ETHERINGTON'S Bay, in *Geography*, a bay on the north-weſt coaſt of the iſland of St. Vincent; a little to the north of Chateau Belair bay.

ETHESIUS Lapis, a name given by ſome authors to the chryſolite.

ETHICAL GOOD, Ethical *poſſible.* See the reſpective articles.

ETHICS, Ηθικη, the doctrine of manners, or the ſcience of moral philoſophy. See Philosophy and Morality.

The word is formed of ηθος, *mores*, *manners*, becauſe the ſcope or object thereof is to form the manners.

Gale makes ethics only the firſt part or branch of moral philoſophy, *viz.* that which regards private perſons, or in a private capacity.

By manners or morals is here meant a way, or manner, of living confirmed by cuſtom or habit, or certain habitudes of doing, or actions which are often repeated, which, if they be according to right reaſon, the morals or manners are ſaid to be good, otherwiſe, evil and vicious.

Hence the object of ethics is the exerciſe of right reaſon in all our affairs, actions, and relations; or it is a man himſelf conſidered as dirigible, and to be conducted according to reaſon: and the end of ethics is to make him good and happy: ſo that if a man conducted himſelf according to right reaſon in all the circumſtances of his actions, affairs, and relations, he would arrive at the higheſt pitch of moral perfection and beatitude.

Whence ethics may be defined a right manner of thinking in order to attain to human felicity, or a ſcience whereby man is directed to conduct his will, and the actions thereof, ſo as to live well and happily. See Will.

The principal, nay, the only topics thereof, are happineſs and manners, whence ariſe two parts or branches of ethics; the firſt on moral happineſs, conſidered as the end; and the ſecond on moral virtues or good manners, as the means to arrive at that end.

ETHICOPROSCOPTÆ, formed of ηθος, *manners*, and προσκοπτω, *offendo*, *I offend*, in *Antiquity*, the name of a ſect. Damaſcenus, in his Treatiſe of Hereſies, tells us, that the denomination of Ethicoproſcoptæ was given to ſuch as erred in matters of morality and things relating to practice that were to be done or to be avoided, &c. who blamed things laudable and good in themſelves, or recommended or practiſed things evil. On this footing the Ethicoproſcoptæ, though a numerous body, were no particular ſect.

ETHIOPIA, in *Ancient Geography*, was a name given to ſeveral countries, both of Aſia and Africa, whoſe inhabitants were either perfectly black or of a ſwarthy complexion; but Ethiopia, in a more reſtricted application of the term, or Ethiopia propria, was limited on the north by Egypt, extending to the leſſer cataract and the iſland Elephantina; on the weſt by Libya interior; on the eaſt by the Red ſea; and on the ſouth by a part of Africa unknown to the ancients, but probably comprehending that ſpace which includes the modern kingdoms of Girgiro, Alaba, Machida, and part of Adel or Zeila. Proper Ethiopia, however, ſeems to have varied in extent at different periods; but for ſeveral ages it ſeems to have been the tract which at this day comprehends the kingdoms of Dongola, Sennaar, and Abaſſia, with part of Adel or Zeila; and conſequently to have taken up 17 degrees of longitude, and to have reached from the tropic of Cancer to within ſix degrees of the line. Some geographers have reſtricted it to the tract of country that lies between Egypt and Abyſſinia, about 600 miles in length, and 500 in breadth, which was called by the Arabian geographers Nubia.

The proper Ethiopia was anciently diſtinguiſhed by a variety of appellations. Sometimes it was called India; ſometimes Cephenia; and moſt uſually Abaſene, in ſound and ſignification approaching very near to the modern Habaſh, Habeſh, or Abaſſia. We alſo find Chaldæa, Aſſyria, and even Perſia denominated Ethiopia by ſome authors of reputation; and it muſt be allowed, that the ancients called all thoſe countries, extending themſelves beyond each ſide of the Red ſea, indiſcriminately India or Ethiopia.

According to the Jews, the LXX, the Vulgate, and other verſions, Cuſh, when applied in ſcripture to a country, is always to be underſtood of the proper Ethiopia. This opinion is ſupported by Philo, Joſephus, Eupolemus in Euſebius, Euſtathius, the author of the Alexandrian Chronicon, and the concurrent teſtimony of the Greek and Latin fathers. See Cush.

Ethiopia did not abound in cities and towns of any conſiderable note. Auxume, Auxumis, or Axome, reckoned the metropolis of Ethiopia, was undoubtedly the ſame city as the modern Axuma, or Axum. This country was extremely mountainous, and therefore the climate in different parts of it was very various. (See ABYSSINIA.) The days and nights, as Ethiopia lay betwixt the tropic of Cancer and the line, were for the moſt part nearly equal. The winds that blew on the mountains were, generally ſpeaking, ſalubrious and pleaſant; but the atmoſphere over the plains ſtagnated and became unwholeſome. The ſoil in thoſe parts that admitted of cultivation was extremely fertile, and produced vaſt quantities of grain, pulſe, and fruit. It abounded with metals, particularly gold, minerals, vegetables, and a great variety of animals. (See ABYSSINIA.) The moſt famous river that waters this country is the Nile. (See NILE.) The chief ports and emporia of ancient Ethiopia were thoſe of Adulis, Mondus, Opore, Moſylon, and the principal city of the Aualitæ, ſeated upon the Red ſea. The Arabs imported from their country into theſe ports fruit, corn, wine, and cloaths; and exported from thence to Ocelis and Muſa, oppoſite harbours in Arabia, ſpices, caſſia, perfumes, ivory, myrrh, and ſeveral other commodities. The moſt noted iſlands pertaining to Ethiopia were Meroe, the Sporades of Agatharcides, Aſtratæ, Ara Palladis, Gythitis, Myronis, Daphnine, Magi, Acanthine, Iſis, Mondus, and Menuthias.

According to Pliny, Ethiopia was anciently divided into 45 kingdoms, of which the moſt powerful and flouriſhing was Meroe; but he does not inform us, whether they were independent of each other, or under one ſupreme head. There is reaſon to believe, however, that the kings of Ethiopia always ruled with an uncontroulable ſway. If we admit the Ethiopian tradition, that a long ſucceſſion of princes, deſcended from Solomon, reigned in this country, it can ſcarcely be denied, that their authority was unlimited, as that of the Hebrew monarch knew no bounds. It appears from Strabo and Pliny, that ſome Ethiopic nations were governed always by queens, whoſe common name was Candace, as that of the Egyptian kings was Pharaoh, and Ptolemy. From Diodorus Siculus we learn, that a great part of Ethiopia was compoſed of ſeveral elective monarchies, the heads of which were choſen out of their prieſts; and that all theſe princes made the laws of their reſpective kingdoms the baſis of their government. According to Diodorus Siculus the laws of Ethiopia agreed in ſubſtance with thoſe of Egypt; which the Ethiopians accounted for by the aſſertion, that Egypt was firſt peopled by colonies that migrated out of their country. Herodotus, however, repreſents the Ethiopians as having been civilized by the Egyptians, and as having learned the cuſtoms and manners of that people at ſo late a period as the reign of Pſammitichus I. Jupiter Ammon, according to the Greek and Latin authors, appears to have been the principal object of religious worſhip in Ethiopia; though the natives paid likewiſe divine honours to Iſis, Pan, Hercules, Æſculapius, and others, whom they conſidered as the greateſt benefactors to mankind; and if theſe authors may be credited, their religion differed not much from that of the Egyptians. Diodorus Siculus tells us, that the Ethiopians valued themſelves upon their being the firſt nation that had a religious eſtabliſhment; and for this reaſon they believed, that their ſacrifices were more acceptable to the gods than thoſe offered by any other people. He aſſures us, however, that ſome of them were atheiſts, who looked upon the ſun, on account of his ſcorching rays, as their implacable enemy. If a tradition of the modern Abaſſines could be relied on, the Ethiopians, or at leaſt a conſiderable part of them, adhered zealouſly to the law of Moſes from the time of Solomon till their converſion to Chriſtianity. According to this tradition, the queen of Sheba, whom our Saviour calls the queen of the ſouth, and who ruled over a powerful nation of Ethiopia, had a ſon by Solomon named Menileck, who was educated at that prince's court, and inſtructed, under the care of his father, in the law of God. Being afterwards anointed king of Ethiopia, and ſent home to take poſſeſſion of his kingdom, at the deſire of ſeveral eminent Iſraelites and doctors of the law that attended him, he introduced his father's religion, which continued among his ſubjects and their poſterity till the time of St. Athanaſius. See ABYSSINIA.

Ethiopia, in ancient times, was a country of vaſt extent, inhabited by different nations; and, therefore, it is natural to ſuppoſe, that a conſiderable variety of languages, or at leaſt of dialects, muſt have prevailed in it. The moſt ancient of theſe was that called the Ethiopic, into which the ſcripture was formerly tranſlated, and in which all the books of the Abaſſines, both ſacred and profane, are written. According to ſome authors, this language nearly reſembles the Chaldee; but, according to Ludolfus, who ſpent 60 years in the ſtudy of it, it bears as great an affinity to the Hebrew and Syriac, and approaches nearer ſtill to the Arabic, from which it appears to be immediately derived. Ludolfus aſſerts, that a competent knowledge of the Hebrew, or any other of the oriental tongues, will enable a ſtudent ſoon to make a very rapid progreſs in the Ethiopic. The pureſt dialect of this tongue was that uſed in the kingdom of Tigré, where Axuma and the old Ethiopian kings reſided. Upon the failure of the Zagæan line, a Sewan prince aſcended the throne, upon which the Amharic dialect was introduced at court, and gradually diffuſed over the whole empire. (See ABYSSINIA.) From comparing the ancient Ethiopic alphabet, as given by the learned Job Ludolfus, in his "Hiſtory of Ethiopia," with the old oriental alphabets, it ſeems not improbable, that ſome of them were derived from the old Aſſyrian, Phœnician, Samaritan, and Syriac characters. The number of letters likewiſe in this alphabet, and the names of ſeveral of them, tend to eſtabliſh the ſame ſuppoſition; though Ludolfus believes theſe characters to have been invented by the Axumites or Ethiopians themſelves, and to be much older than even the Cufic character of the Arabs. The Ethiopians both write and read from the left hand to the right, contrary to the cuſtom of the orientals: a circumſtance which indicates that their alphabet was not entirely of the ſame extraction with that of the Arabs.

The Ethiopians agreed in ſeveral points with the Egyptians, though they had many cuſtoms peculiar to themſelves, ſome of which were very ſingular and uncommon. From this mutual agreement in moſt of their laws, their ſplendid funerals, the deification of their princes, the ſeveral colleges of prieſts, circumciſion, and moſt of their ſacred and civil inſtitutions, it is highly probable that the ſame arts, ſciences, and learning, as well as religion, prevailed in both nations.

The Ethiopians were naturally bold and intrepid, but violent in their temper. They likewiſe ſurpaſſed the people of moſt other nations in beauty and ſize, to which a proportionable degree of ſtrength was generally annexed. According to various authors, the proper ancient Ethiopians were, in general, perfectly black, as we find their poſterity at this day, though thoſe of ſome particular cantons were white, called by Pliny white Ethiopians. Their women were ſtrong and luſty, and brought forth their children with little pain. From the teſtimony of Herodotus, compared with the relations of ſome modern authors, it is not unlikely, that they died of old age, a few only excepted, who fell by the ſword, or were devoured by wild beaſts, as Salluſt has obſerved of the ancient Africans. Anc. Un. Hiſt. vol. xvi. See Abyssinia and Cush.

Ethiopia, in *Modern Geography*, is a denomination including the countries of Nubia, Abyſſinia, Abeſh or Abex, and Anian, which are bounded by Egypt and the deſart of Barca on the north; by the Red ſea and the eaſtern ocean on the eaſt; by Zanguebar and Caffraria on the ſouth; and by Guinea, Nigritia, and Zaara, on the weſt. Nevertheleſs, all the countries ſtill, according to the ancient diviſion, that lie almoſt in a ſtraight line from Egypt to the Cape of Good Hope, may be comprehended under the general name of Ethiopia. Ethiopia is divided into Upper and Lower, the former including Nubia and Abyſſinia; and the latter comprehending all the kingdoms ſouth of the equinoctial line, as Congo, Lower Guinea, Caffraria, Monomotapa, &c. which ſee reſpectively.

ETHIOPIC Version. See Bible, *Ethiopic*.

Ethiopic *Year*. See Year.

ETHLEC, in *Ancient Geography*, a town of Upper Mœſia, according to Antonine's Itinerary.

ETHMOID, or Ethmoidal, in *Anatomy*, a name given to one of the bones of the head. See Cranium.

ETHNARCHA, Ethnarch, formed of εθνος, *nation*, and αρχη, *command*, a governor and ruler of a nation.

There are ſome medals of Herod I. ſurnamed the *Great*, on one ſide whereof is found Ηρωδου, and on the other Εθναρχου, q. d. *Herod* the *Ethnarch*. After the battle of Philippi, we read that Antony, paſſing over into Syria, conſtituted Herod and Phaſael his brother tetrarchs, and in that quality committed to them the adminiſtration of the affairs of Judea. (Joſ. Ant. lib. xiv. cap. 23.) Herod therefore had the government of the province before ever the Parthians entered Syria, or before Antigonus's invaſion, which did not happen till ſix or ſeven years after Herod was commander in Galilee. (Joſ. lib. xiv. cap. 24, 25.) Conſequently Herod was then truly ethnarch, for he can be no otherwiſe denominated; ſo that it muſt have been in that ſpace of time that the medals were ſtruck, which only gave him this title: which medals are a confirmation of what we read in hiſtory of the government which that prince was intruſted with before he was raiſed to the royalty.

Joſephus gives Herod the appellation of tetrarch in lieu of that of ethnarch; but the two terms come ſo near to each other, that it is eaſy to confound them together.

Though Herod the Great left by will to Archelaus all Judea, Samaria, and Idumea, yet Joſephus tells us he was then only called ethnarch.

ETHNOPHRONES, in *Antiquity*, a ſect of heretics in the ſeventh century, who made a profeſſion of Chriſtianity, but joined thereto all the ceremonies and follies of paganiſm, as judicial aſtrology, ſortileges, auguries, and other divinations.

They derive their denomination from εθνος, *nation*, and φρην, *thought*, *ſentiment*. q. d. *paganizers*, or perſons whoſe thoughts or ſentiments were ſtill heathen or gentile.

They practiſed all the expiations of the gentiles, celebrated all their feaſts, and obſerved all their days, months, times, and ſeaſons. See Damaſcenus, Hæreſ. N° 94.

ETHOLOGUS, among the *Ancients*, a mimic, or actor, who could repreſent all the various habits and diſpoſitions of the mind.

ETHOPŒIA, or Ethopea, in *Rhetoric*, called alſo *Ethology*, a draught or deſcription, expreſſing the manners, paſſions, genius, tempers, aims, &c. of another perſon.

The word is of Greek original, being formed of εθος, *mos*, *conſuetudo*, and ποιεω, *facio*, *fingo*, *deſcribo*. Quintilian, lib. ix. cap. 2. calls this figure *imitatio morum alienorum*; and in Greek, μιμησις, *imitation*. In Engliſh we denominate it a *picture* or *character*.

Such is that beautiful paſſage in Salluſt, in his "Bellum Catilinarium," wherein he gives us a picture of Cataline: "He had an uncommon ſtrength both of body and mind, but an ill-turned and wicked diſpoſition. When very young, his great pleaſure was in inteſtine broils, rapine, ſlaughter, and civil diſcord. His body was formed to undergo faſting, cold, and watching, beyond all belief. His mind was daring, deceitful, and various, and could imitate or accommodate itſelf to every body; he was extremely covetous of other people's goods, and profuſe of his own. His luſts and deſires were very high; his ſtock of eloquence conſiderable, but he had little or no diſcretion."

The ethopœia is divided into *proſopographia* and *ethopœia*, properly ſo called; the former of which is a picture of the body, countenance, make, dreſs, gait, &c. and the latter of the mind.

ETHULIA, in *Botany*, a name concerning whoſe origin or meaning we have met with no conjecture. Linnæus its author rarely explained names of his own contrivance, nor is any thing upon this occaſion mentioned in his ſon's Decas Prima Plantarum, where *Ethulia* firſt appeared. Could he poſſibly allude to the remote country whence it came, as *e*, *extra*, (beyond) *Thule*, ſuppoſed by the ancients the uttermoſt part of the earth? If the plant had been of American origin, ſuch an appellation would, not inelegantly, have alluded to the famous prophecy in Seneca's Medea, ſo expreſſive of the diſcovery of the weſtern world, and ending

——"nec ſit terris
Ultima Thule."——

It was however ſuppoſed to come from Ceylon, and is actually a native of the banks of the Nile. If the above conjecture be inadmiſſible, the name muſt depend on its harmony for protection. Linnæus might well be glad to get rid of the harſh *Sparganophorus* of Vaillant, to which he would object as compoſed of *Sparganium*, a generic name already eſtabliſhed. But it is probable he did not at firſt obſerve that Vaillant's genus was his *Ethulia*, though he ſoon recognized it. Linn. Gen. 413. Schreb. 545. Willd. Sp. Pl. v. 3. 1740. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 158. Juſſ. 184. Gærtn. t. 164. (Sparganophorus; Vaill. Act. Paris. Ann. 1719. Gærtn. t. 165.) Claſs and order, *Syngeneſia Polygamia-æqualis*. Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* rounded, ſimple, of many linear, equal, ſpreading-pointed ſcales. *Cor.* compound, diſcoid. Florets all fertile, numerous, uniform, tubular, funnel-ſhaped, with ſome ſpace between them; their limbs five-cleft, erect. *Stam.* Filaments five, very ſhort, capillary; anthers united into a cylindrical tube. *Piſt.* Germen angular; ſtyle thread-ſhaped, the length of the ſtamens; ſtigmas two, recurved. *Peric.* none, except the permanent calyx. *Seeds* ſolitary, truncated, top-ſhaped, five-ſided, five-furrowed; crown none, except a prominent margin. *Recept.* naked, convex, dotted with minute excavations.

Eſſ. Ch. Receptacle naked. Seed-down none. Florets tubular, five-cleft, numerous. Scales of the calyx pointed.

This is but a vague and confuſed genus, depending properly on the three following ſpecies only.

1. E. *conyzoides*. Linn. Sp. Pl. 1171. L. fil. Dec. Pl. Rar. 1. t. 1. "Flowers panicled."—Seeds of this were

ſent by Profeſſor David Van Royen to Linnæus, who raiſed them in his ſtove at Upſal, and the plant proving new, was deſcribed and figured by his ſon, in a work of which only two faſciculi ever appeared. Linnæus ſuppoſed it a native of Ceylon, which may poſſibly be correct. No new information appeared concerning it, till it was mentioned in the Hortus Kewenſis as ſent by Thouin, and ſoon afterwards Vahl diſcovered it to be the *Kahiria* of Forſkall, ſo that we hence learn it to be certainly a native of the muddy banks of the Nile, where it flowers early in November. The *root* is annual, fibrous. *Stem* four feet high, alternately branched, hollow, downy, leafy. *Leaves* alternate, on ſhort ſtalks, lanceolate, pointed, equally ſerrated, fragrant, downy beneath, three inches long; without ſtipulas. *Flowers* pale blue, in compound corymboſe panicles about the tops of the branches, remarkable for the ſlender and diſtant tubes of their florets. The *ſeeds* form an almoſt globoſe head; each of them is crowned with a pale undivided angular border.

2. E. *Sparganophora.* Linn. Sp. Pl. 1171. (Sparganophorus Vaillantii; Gærtn. v. 2. 395. t. 165.) "Flowers in ſeſſile axillary cluſters. Calyx-ſcales recurved."—This we know only from the work of Vaillant, (from whom Linnæus adopted it,) and that of Gærtner; nor is its native country aſcertained. The *leaves* are ſaid to be like thoſe of Golden Rod. *Seeds* exactly like the laſt in general ſtructure, nor does there ſeem any doubt of their belonging to one and the ſame genus.

3. E. *Struchium.* Swartz. Prod. 111. (Struchium; Browne Jam. 312. t. 34. f. 2.) Flowers axillary, ſeſſile, moſtly ſolitary. Calyx with ſtraight ſpinous points.—Gathered by Browne in Jamaica. *Stem* herbaceous, two or three feet high, leafy, ſmoothiſh. *Leaves* elliptic-lanceolate, four or five inches long, pointed, ſtrongly ſerrated, thin, very ſlightly pubeſcent, on ſtalks an inch in length. *Flowers* ſmall, axillary, ſeſſile, either ſolitary or in pairs, or if more together, they have ſmaller leaves between them. We preſume the ſtraight ſpinous points of the calyx-ſcales will afford a certain ſpecific difference between this and the laſt, whether their foliage be different or not.

In his firſt Mantiſſa, p. 110, Linnæus added three ſpecies to his genus *Ethulia.* Of theſe *E. tomentoſa* muſt be entirely ſtruck out of the ſyſtem, being no other than his own *Artemiſia chinenſis*, and not having either the habit or characters of an *Ethulia.* The ſecond is *E. divaricata*, Burm. Ind. 176. t. 58. f. 1. (Chryſanthemum bengalenſe anguſtifolium puſillum, ſummo caule ramoſum; Pluk. Phyt. t. 21. f. 4.) Leaves linear, toothed, decurrent. Flowers ſolitary, ſtalked, terminal. Stem divaricated.—Native of rice-fields in Malabar. *Koenig.* *Root* annual. *Stem* three or four inches high, erect, much branched in a corymboſe manner; branches leafy, quadrangular, winged, ſomewhat cottony. *Leaves* alternate, linear-lanceolate, toothed, running down into the wings of the branches. *Flowers* on ſhort, ſimple, ſolitary, terminal ſtalks; *Calyx* of numerous, imbricated, ſharp and ſomewhat ſpinous, ſpreading, purpliſh ſcales. *Seeds* without any crown.—We have, as Willdenow has already done, preſumed to correct the deſcription of Linnæus, and his quotation of Burmann. Linnæus moreover quotes his own *Artemiſia minima*, Sp. Pl. ed. 1. n. 19, with the original ſpecimen before him, for this *Ethulia*, but very erroneouſly, and his citation of Burmann is ſo placed as to imply that he had committed the ſame fault, which is not true. We cannot but obſerve here that Burmann in his Flora Indica has copied *E. conyzoides* and *E. Sparganophora* from Linnæus, without any real knowledge of them, ſo that his authority is of no avail reſpecting thoſe ſpecies. Gærtner, v. 2. 389. t. 164, retains this *E. divaricata* as the only real *Ethulia*, adding a good ſynonym from Plukenet (who figures the plant twice), Chryſanthemum parvum ramoſiſſimum, membranaceo-caule maderaſpatenſe; Pluk. Phyt. t. 160. f. 5. Gærtner therefore preſerves the name and genus of Vaillant's *Sparganophorus*, which he contends is a very diſtinct genus from this plant. In the laſt particular he appears to be right, but the above three ſpecies unqueſtionably conſtitute what Linnæus meant by *Ethulia*, and they only agree with his generic deſcription, ſo that the *divaricata* ought perhaps to be referred, notwithſtanding its want of a ſeed-crown, to the *Grangea* of Adanſon and Juſſieu, as the latter ſuſpects, or rather to make a genus by itſelf. (See GRANGEA.) Juſſieu indeed preſerves Browne's *Struchium* as a genus, but, as we preſume, improperly.

One more ſuppoſed *Ethulia* remains to be noticed, named *bidentis*, Mant. 110, from its reſemblance to *Bidens tripartita.* This has nothing to do with the genus under conſideration, being the very identical *Flaveria capitata* of Juſſieu, of which we ſhall ſpeak under that name hereafter. It is a native of Chili.

With the *Ethulia uniflora* of Walter and Willdenow we are not at all acquainted. S.

ETIENNE, in *Biography*, the name of a family who have been celebrated as learned printers, and are more commonly known by the epithet of Stephanus, or in Engliſh by that of the learned Stephens. The founder of the family was Henry, a printer at Paris. He is chiefly diſtinguiſhed as the editor of a Pſalter, in which the compoſitions were divided into verſes, and diſtinguiſhed by figures, being the firſt book of Scripture in which this practice was obſerved. He died at Lyons, leaving behind him three ſons, all eminent printers, of whom the ſecond was,

ETIENNE, ROBERT. This young man worked at firſt under Simon de Colines, who had married his mother, and then ſet up in buſineſs for himſelf at Paris. He had received a very liberal education, and was well acquainted with the ancient languages, and was deeply ſkilled in principles of ſound criticiſm. He carried the art of typography to a very high pitch of excellence, as a number of his books well known at preſent will teſtify. His office is ſaid to have reſembled a learned ſeminary, in which the Latin language was the only one allowed to be ſpoken by all the perſons employed by him. He eſtabliſhed an early reputation by the editions of the bible in different languages. He was the firſt perſon who introduced the diviſion of the whole into verſes; of which, we are informed, he made the neceſſary preparations, as he was on a journey on horſeback from Paris to Lyons. Theſe diviſions have been uſeful as marks for reference, but in other reſpects they have been injurious to the work, on account of the faultineſs of the diviſions which not unfrequently give a wrong ſenſe to important paſſages of the ſacred writings. In the year 1532 he publiſhed his excellent "Theſaurus Linguæ Latinæ" in two volumes folio. This work obtained a very high reputation, and has paſſed through many editions: the beſt are ſaid to be that printed in London in 1734, and the one printed at Baſil in 1740. Both editions conſiſt of four volumes folio. In the year 1539 the reputation of Robert attracted the attention of Francis I. who reimburſed him ſome of his expences in procuring manuſcripts and founding new types, and gave him the honour of king's printer for Greek and Latin books. At the reformation this worthy printer, in common with many biblical critics, fell under the ſuſpicion of hereſy, and endured a long perſecution excited by the doctors of the Sorbonne, who, in the year 1548 unanimouſly decreed that his bible with a verſion by Leo Judæ, and notes, ought to be ſuppreſſed, and placed in the liſt of prohibited books. By many liberal and reſpectable perſons Etienne was ſupported againſt the fanaticiſm of bigots and prieſts, but, at length, he thought it adviſeable to withdraw to Geneva, where he more openly avowed himſelf a friend to the reformed religion. He felt himſelf called on to vindicate his conduct, and publiſhed an apology, in which he retaliated upon his perſecutors, and the church, by whom he had been driven into a kind of exile. At Geneva he continued to follow his profeſſion, and publiſhed many books in favour of the Proteſtant cauſe. He was elected burgher of Geneva, and lived in habits of friendſhip with Beza and Calvin. He died in the year 1559, at the age of fifty-ſix. He has been, ſince his death, to the preſent day, the theme of admiration with the learned, and by the illuſtrious De Thou he was conſidered as better entitled to the gratitude of his country, by the perfection which he gave to the art of printing, than thoſe warriors who had extended the boundaries of the French empire. Moreri.

Etienne, Charles, a phyſician of the faculty of Paris, who is conſidered by his biographers as an honour to the age in which he lived, in conſequence of the extent and variety of his attainments. He was born about the year 1503. His father, Henry Etienne, and his brothers, Francis and Robert, were all celebrated for the ingenuity with which they cultivated the art of printing. But this family was not leſs unfortunate than ingenious; for, being attached to the cauſe of the Proteſtant reformation, ſome of them were baniſhed from France, and others died in priſon. Charles, however, during theſe troubles, lived and flouriſhed at Paris, where he had for many years practiſed his profeſſion, when his brother Robert became the object of perſecution, and fled to Geneva. He immediately undertook the ſuperintendence of his printing-office, which he continued to manage for ſeveral years, in the hope of effecting the reſtoration of his brother, practiſing medicine at the ſame time with his former diſtinction and ſucceſs. Robert died at Geneva, however, in 1559; and Charles terminated his life unfortunately, a few years afterwards, having died in a dungeon in 1564, at the age of about ſixty.

Dr. Etienne, the ſubject of this article, made ſeveral diſcoveries of minor importance in anatomy, which had eſcaped his predeceſſors, eſpecially Galen, of whom he was a great admirer; he publiſhed ſome anatomical figures, the execution of which, however, was claimed by a ſurgeon of the name of Riviere, and generally allowed to be his; but the explanations were admitted to be Etienne's. He publiſhed a great number of works, ſome of which have no connection with his profeſſion, eſpecially the hiſtories of Lorraine, of Flanders, and of the dukes of Milan. The works relative to medicine, beſides the anatomical book juſt mentioned, were principally on botanical ſubjects. He alſo wrote a volume, conſiſting of three books, "De Nutrimentis," Paris, 1550. Eloy.

Etienne, Henry, the ſon of Robert, was born at Paris in 1528, and became diſtinguiſhed as one of the moſt learned men of his time. His father ſpared neither pains nor expence in his education, and the youth had a great facility in acquiring the Greek language. At the age of eighteen he aſſiſted his father in collating the MSS. of Dionyſius Halicarnenſis. After he had performed this buſineſs he ſet out on his travels; ſtaid ſome time in Italy, where he became well acquainted with the learned men of that country, and obtained much valuable information from the Italian libraries. From Italy he came to England, and from thence he paſſed through the Low Countries in his way to Paris, whither he returned at the moment his father was driven from that city. Here he followed the united profeſſions of printer and editor. In 1554 he publiſhed the Odes of Anacreon from the MSS. which he found in Italy. He accompanied his edition with fragments of Sappho and other lyric poets, and with an elegant metrical verſion. To him the learned are likewiſe indebted for various other Greek authors, publiſhed from MSS. which he had collected in his travels, all of which he corrected and enriched with valuable annotations. In 1572 he publiſhed his "Theſaurus Linguæ Græcæ," in four volumes folio, a capital companion to the Latin Theſaurus by his father. Scapula made an abridgement of this vaſt work, which greatly hindered the ſale of the original, and thus defrauded the learned author of the recompence to which he had the moſt ſolid claim. This valuable man was protected by Henry IV. of France, who was ſo far attached to him, that he employed him in a work entitled "Sur la precellence de la Langue Francoiſe." He was, however, too deeply imbued with the liberal principles which real literature almoſt always infuſes in the minds of her votaries, to eſcape the malice of the monks. They brought a proſecution againſt him for his "Preparation á l'Apologie pour Herodote." Appriſed of his great danger, and well knowing the rancour of his enemies, he fled from the city and took refuge in the mountains of Auvergne. Scarcely had he left the city, when finding that he had eſcaped their cruel fangs, they burnt the excellent man in effigy, regretting, no doubt, that they had not his perſon on which to wreak their vengeance. After this Etienne reſided chiefly at Geneva, though he made occaſional viſits to his literary friends in Germany and France. He was ſubject to many difficulties, and doomed to other and ſevere perſecutions, which at length ſo far broke his ſpirits as to cauſe derangement, and in this ſtate, as well as in poverty, he died at an alms-houſe at Lyons in 1598. Beſides editing the Poetæ Græci Principes; Maximus Tyrius; Diodorus Siculus; Medicæ artis Principes poſt Hippoc. and Galen; and the Nov. Teſt. Græc., to which he prefixed an admirable preface; he was author of ſome excellent pieces, beſides what have been already mentioned; *viz.* Dialogues "De bene inſtituendis linguæ Græcæ ſtudiis;" "De criticis veteribus Græcis et Latinis," and other pieces in the French language, as well in verſe as in proſe. He was a man of many ſingularities, but truly reſpectable, and highly reſpected. He left ſeveral children, of whom his ſon Paul ſucceeded him in his Genevan printing-office, and inherited a ſhare of his reputation. Moreri.

Etienne, *Saint*, in Latin *Fanum Sancti Stephani*, or *Furania*, in *Geography*, a conſiderable town of France, in the department of the Loire, chief place of a diſtrict of the ſame name, with a population of 16,259 individuals. It is ſituated on the river Furan, 36 miles S.W. of Lyons, and 348 miles S. by E. of Paris. N. lat. 45° 22′. The town is divided into two cantons, Eaſt and Weſt, the former with three communes and 12,735 inhabitants, the latter with three communes and 14,669 inhabitants; the whole canton has a territorial extent of 92½ kilometres. There are at Saint Etienne and in the neighbourhood ſeveral manufactures of ſwords and fire arms, cutlery, and hardware of all ſorts, ribbands, ſilks, and good bleaching grounds. The diſtrict abounds with coal-mines, and the proximity of two large rivers, the Rhône and Loire, affords great facility for the tranſport of the produce of the manufactures.

As chief place of a diſtrict, Saint Etienne has a ſub-prefect, two courts of juſtice, and a regiſter office. The diſtrict contains 9 cantons, 76 communes, and 99,261 inhabitants,

ants, on a territorial extent of 1142½ kiliometres.—Alſo, a ſmall town of France, in the department of the Maritime Alps, chief place of a canton in the diſtrict of Puget-Theniers, with a population of 1689 individuals; its canton has a territorial extent of 212½ kiliometres, and three communes, with 3089 inhabitants.

Etienne *de Baigorry*, *Saint*, a town of France, in the department of the Lower Pyrenées, chief place of a canton in the diſtrict of Mauléon, with a population of 6187 individuals. The canton contains 10 communes and 10,939 inhabitants, on a territorial extent of 210 kiliometres.

Etienne *de Cuines*, *Saint*, a ſmall town of France, in the department of Montblanc, chief place of a canton in the diſtrict of St. Jean de Maurienne, with a population of 830 individuals. The canton has a territorial extent of 117½ kiliometres and 6 communes, with 6496 inhabitants.

Etienne *de Lugdarès*, *Saint*, a ſmall town of France, in the department of the Ardèche, chief place of a canton in the diſtrict of l'Argentiere, with a population of 1509 individuals. The canton has ſeven communes and 3439 inhabitants, on a territorial extent of 185 kiliometres.

Etienne *de Montluc*, *Saint*, a town of France, in the department of the Lower Loire, chief place of a canton in the diſtrict of Savenay, with a population of 4118 individuals. The number of the inhabitants of the canton amounts to 12,453; they are diſperſed in five communes, on a territorial extent of 272½ kiliometres.

Etienne *de Saint Geoire*, *Saint*, a ſmall town of France, in the department of the Iſère, chief place of a canton in the diſtrict of St. Marcellin. It has 1546 inhabitants, and its canton compriſes, on a territorial extent of 162½ kiliometres, 13 communes, with a population of 9381 individuals.

Etienne *en Dévoluy*, *Saint*, a ſmall town of France, in the department of the Upper Alps, chief place of a canton in the diſtrict of Cap, with only 766 inhabitants: but the canton has four communes, and a population of 2184 individuals, on a territorial extent of 262½ kiliometres.

Etienne *les Orgues*, *Saint*, a ſmall town of France, in the department of the Lower Alps, chief place of a canton in the diſtrict of Forcalquier, with a population of 984 individuals. The canton has a territorial extent of 272½ kiliometres, 12 communes, and 4260 inhabitants.

ETIOLATION *of Plants*, in *Gardening*, the rendering them white, criſp, and tender, by excluding the action of light from them. See Blanching.

ETIQUETTE, a French term, primarily denoting a ticket or title affixed to a bag or bundle of papers, expreſſing its contents. It is alſo uſed when applied to the Spaniſh and ſome other courts, to ſignify a particular account of what is to be done daily in the king's houſhold, and in the chief ceremonies relating to it. It likewiſe denotes thoſe forms that regulate the decorum of conduct towards perſons of various ranks and ſtations.

ETIVAZ in *Geography*, a ſmall town of Switzerland, in that part of the canton of Berne which is called the Ober Land, or Upper Country, being at the foot of the higheſt Alps, and extending to the glaciers, or ice mountains. It is ſituated in the diſtrict of Geſſenay, and is remarkable for its mineral ſprings, the water of which has a ſulphureous taſte.

ETLINGEN, or Ettlingen, a ſmall town of Germany, in the grand duchy of Baden, ſituated on the river Alb, between Pfortzheim and Raſtadt, at the diſtance of 12 miles from each. N. lat. 48° 55'.

ETMARSHAUSEN, or Etmershausen, a ſmall town of Germany, in the duchy of Saxe Coburg, in the diſtrict of Saltzungen, remarkable only for the following inſcription, which is engraved on an old garden gate of ſtone, in Latin characters: "wer weiſz obs wahr iſt," (who knows whether it be true.) It is become a proverbial ſaying in that part of Saxony, and frequently uſed as a polite inſinuation that a perſon is ſuſpected of having rather deviated from or embelliſhed the truth; people then obſerve that what has been related is engraven at the garden gate at Etmarſhauſen. The origin, occaſion, or motive of the inſcription itſelf, has never yet been explained, and has puzzled ſeveral antiquaries of the neighbourhood.

ETMASER, a town of Arabia, in the province of Yemen; 36 miles N. of Chamir.

ETMULLER, Michael, in *Biography*, an eminent phyſician, was born at Leipſic on the 26th of May, 1644. Poſſeſſing a taſte for the ſciences which his native city afforded him the moſt ample means of cultivating, he diligently ſtudied under the celebrated profeſſors of that period. He afterwards ſpent a conſiderable time in travelling through France, England, Holland, Italy, and Germany, with a view to the farther acquiſition of knowledge; and on his return took the degree of doctor of medicine at Leipſic in Auguſt 1668. In the year 1676, he was appointed profeſſor of botany in that univerſity, and extraordinary profeſſor of ſurgery and anatomy. He fulfilled thoſe offices with great applauſe; and his death, which happened on the 9th of March, 1683, when he was but 39 years of age, was generally regretted by the faculty of Leipſic. The diſorder, which occaſioned it, was contracted while he was employed in ſome chemical experiments. He was a very voluminous writer, and his works were deemed ſufficiently intereſting at the time of their publication to be tranſlated into moſt of the European languages. His medical practice and opinions were built upon the theory of Sylvius de la Boë, and the chemical ſect.

Etmuller, Michael Ernest, ſon of the preceding, was born at Leipſic on the 26th of Auguſt, 1673; and, after having ſtudied at Zittau, Altemberg, and other ſchools of Germany, he took the degree of doctor of medicine at his native place, in 1697. He afterwards travelled to the moſt eminent univerſities of Europe, and became ſucceſſively profeſſor of anatomy, of philoſophy, and of pathology at Leipſic. He had likewiſe been two years director of the Academia Naturæ Curioſorum, when his death occurred, on the 25th of September, 1732. He has left ſome diſſertations of his own, but is chiefly known as the editor of the works of his father.

ETNA. See Ætna.

ETOBESA, or Etobema, in *Ancient Geography*, a town of Spain, in Edetania, mentioned by Livy under the name of Etoviſſa, and ſituated at ſome diſtance W. of Valencia.

ETOCETUM, a place in the iſle of Albion, according to the Itinerary of Antonine, which Gale fixes at Wall, near Litchfield.

ETOILE, in *Geography*, a town of France, in the deparment of Drôme, and diſtrict of Valence; 3 leagues N.W. of Creſt.

ETOLIA. See Ætolia.
